The *Handbook of the Birds of the World* is, as reviewers never cease to indicate, an astonishing achievement, and their critical rapture has consistently been mixed with a sense of awe – almost disbelief – that such a project should have come to pass. The notion of the time being ripe for so massive an enterprise took many people, myself included, by surprise; but despite the dithering costs of such a project and the dizzying tasks involved in its management, it is certainly the case that much of the basic information on the bird species of the world has now been generated and is available for assembly. A hundred years ago *HBW* would have been unthinkable: so much of the planet remained to be explored, so many species remained to be discovered. Fifty years ago the picture was still very obviously incomplete; and even if new species were by then becoming much harder to find, our general biological knowledge of a high proportion of birds was abidingly feeble. The past quarter-century, however, has witnessed a radical transformation in our information base, as the growth of worldwide tourist markets and the proliferation of Peterson-style fieldguides has elevated birdwatching into a major international pursuit. The rarest birds have accordingly been pursued, their means of surefire identification frequently established, their habits and habitats broadly documented. *HBW* caught the wave and is riding it triumphantly to shore.

From the foreword of this volume, by DR NIGEL J. COLLAR

Jacket illustration by FRANCESC JUTGLAR
Common Barn-owl (*Tyto alba*)
Fringed Coquette (*Lophornis magnificus*)

Authors of Volume 5

Dr D. L. Altshuler

Graduate Research Fellow, Department of Zoology, University of Texas, Austin, Texas, USA.

R. Berkley

Owl Research Institute, Missoula, Montana, USA.

Dr M. D. Bruce

Biocon Research Group, Turrumurra, Australia.

R. Bündgen

Department of Ornithology, Alexander König Research Institute and Museum of Zoology, Bonn, Germany.

Dr W. A. Calder

Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, Arizona, USA.

R. J. Cannings

Freelance Biologist and Consultant, Naramata, British Columbia, Canada.

Dr P. Chai

Department of Zoology, University of Texas, Austin, Texas, USA.

P. Chantler

Freelance Ornithologist, Kent Ornithological Society, England.

N. Cleere

Freelance Ornithologist, England.

M. Cohn-Haft

Department of Biological Sciences and Museum of Natural Science, Louisiana State University, Baton Rouge, Louisiana, USA; currently based in Manaus, Brazil.

Dr N. J. Collar

Research Fellow, BirdLife International, Cambridge, England.

C. Deppe

Owl Research Institute, Missoula, Montana, USA.

P. L. Enríquez Rocha

El Colegio de la Frontera Sur, San Cristóbal de las Casas, Chiapas, Mexico.

Professor J. Fjeldså

Zoologisk Museum, Københavns Universitet, Denmark.

M. Heindl

Munich, Germany.

I. Heynen

Wuppertal, Germany.

Dr C. Hinkelmann

Bardowick, Germany.

D. W. Holt

Owl Research Institute, Missoula, Montana, USA.

Dr D. T. Holyoak

Consultant, Cornwall, England.

Dr J. S. Marks

Assistant Professor, Division of Biological Sciences and Wildlife Biology Program, University of Montana, Missoula, Montana, USA.

Dr H. Mikkola

Department of Applied Zoology and Veterinary Medicine, University of Kuopio, Kuopio, Finland.

Dr P. D. Olsen

Australian National University, Canberra, Australia.

J. L. Petersen

Owl Research Institute, Missoula, Montana, USA.

Dr A. T. Peterson

Associate Professor and Curator, University of Kansas Natural History Museum, Lawrence, Kansas, USA.

Dr D. R. Powers

Professor, Biology Department, George Fox University, Newberg, Oregon, USA.

J. L. Rangel Salazar

El Colegio de la Frontera Sur, San Cristóbal de las Casas, Chiapas, Mexico.

Dr J. H. Rappole

Research Scientist, Conservation and Research Center, National Zoological Park, Smithsonian Institution, Front Royal, Virginia, USA.

Dr M. S. Roy

Lecturer and Research Scientist in Evolutionary and Conservation Genetics, University of Otago, Department of Zoology, Dunedin, New Zealand.

C. Sánchez Osés

Department of Ornithology, Alexander König Research Institute and Museum of Zoology, Bonn, Germany.

Professor K. L. Schuchmann

Curator and Lecturer, Department of Ornithology, Alexander König Research Institute and Museum of Zoology, and University of Bonn, Bonn, Germany.

Dr P. E. Scott

Assistant Professor of Life Science, Indiana State University, Terre Haute, Indiana, USA.

K. P. Segars

Owl Research Institute, Missoula, Montana, USA.

Professor F. G. Stiles

Professor and Curator of Ornithology, Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Bogotá, Colombia.

B. T. Thomas

Formerly Independent Researcher, Venezuela; late of Virginia, USA.

Dr A. A. Weller

Department of Ornithology, Alexander König Research Institute and Museum of Zoology, Bonn, Germany.

Dr D. R. Wells

Independent Researcher, Illington, Norfolk, England; formerly University of Malaya, Kuala Lumpur, Malaysia.

K. L. Wood

Owl Research Institute, Missoula, Montana, USA.

T. Züchner

Research Associate, Department of Ornithology, Alexander König Research Institute and Museum of Zoology, Bonn, Germany.

Foreword

Risk Indicators and Status Assessment in Birds

*And you know something is happening,
But you don't know what it is...
Do you, Mr Jones?*

– Bob Dylan, *Ballad of a thin man*

Introduction

The *Handbook of the Birds of the World (HBW)* is, as reviewers never cease to indicate, an astonishing achievement, and their critical rapture has consistently been mixed with a sense of awe – almost disbelief – that such a project should have come to pass. The notion of the time being ripe for so massive an enterprise took many people, myself included, by surprise; but despite the dithering costs of such a project and the dizzying tasks involved in its management, it is certainly the case that much of the basic information on the bird species of the world has now been generated and is available for assembly. A hundred years ago *HBW* would have been unthinkable: so much of the planet remained to be explored, so many species remained to be discovered. Fifty years ago the picture was still very obviously incomplete; and even if new species were by then becoming much harder to find, our general biological knowledge of a high proportion of birds was abidingly feeble. The past quarter-century, however, has witnessed a radical transformation in our information base, as the growth of worldwide tourist markets and the proliferation of Peterson-style fieldguides has elevated birdwatching into a major international pursuit. The rarest birds have accordingly been pursued, their means of surefire identification frequently established, their habits and habitats broadly documented. *HBW* caught the wave and is riding it triumphantly to shore.

To shore, to conclusion, to an end; and, when it ends, sometime around 2010 if all goes to plan, there will lie in our hands a truly wonderful resource, a breathtaking work of reference, a masterful avian encyclopedia, a grid of information across the biosphere such as has never previously existed for any major group of animals or plants. And what else? A little less mystery, perhaps; and a lot fewer birds. I do not just mean fewer individual birds, fewer populations, and smaller ranges for almost everything except the human commensals, although this in itself is a deeply depressing prospect; I also mean fewer bird species.

There is, of course, a connexion between these things. It is an odd circumstance – everyone looks forward to the next volume of *HBW*, bearing, as we know it will, the most up-to-date information on a great swathe of the world's avifauna, yet most of us will also have at least an inkling that these new data owe their existence to events over which we may be decidedly less enthusiastic. Birdwatchers and biologists get to ever more remote places – islands, interiors – by virtue of new airports, new logging roads, new tourist facilities. They arrive as tiny components of the great machinery of economic development which, in a few short years, mutilates natural landscapes and human cultures beyond recognition and brings Coca-Cola, television, chainsaws, DDT and debt to every cultivable corner of the planet. By the year 2010 not only will we know more about birds than ever before (and be able to find much of that knowledge in *HBW*); we will also have most of them *completely surrounded*.

We can therefore anticipate learning very early in the new millenium the full meaning of the notion of global stewardship; if not, we will discover instead what it might be like to visit a zoo in which all of the cages are empty. So perhaps the foremost aspiration within this notion must be the absolute minimisation of extinction at the global level. There are, of course, many plans to be devised and implemented in order to staunch the steady outflow of our planet's biological diversity at the distributional, population and genetic levels – all those disappearing individuals – but this is an area riven with political and procedural complexity, and a satisfactory review of the situation, while urgently required, will take several years. Meanwhile we must make no less haste in reaching a better understanding of the early warning signs of endangerment, and a clearer appreciation of the means by which we can confidently and consistently register species as in such danger: the sooner these things are sorted, the surer we can be of preventing too great a taxic haemorrhage by the time *HBW* has run its spectacular course.

A catalogue of risk indicators

We have had many years – indeed, several centuries – to accumulate the evidence; yet we still cannot be confident of all the elements that render species susceptible to extinction. Extinction probabilities appear to vary considerably from one species to another, for reasons we cannot yet – or cannot always – discern; as Simberloff (1986) put it, “Most of the traits said to make a species extinction-prone are eminently reasonable, but... the problem is that for every trait listed one can find species that have the trait and have *not* gone extinct.”

The most obvious and immediate explanation for this problem is that it is traits of one sort or another *in combination* that produce extinctions. Certainly this idea lies behind the widely used metaphor of a vortex to describe the extinction process, where one relatively innocent factor compounds, and is compounded by, other such factors to send a species into an accelerating downward spiral. The interactions of these factors are likely to become increasingly complex as the process of decline continues yet, other than in the skeletal reviews of Frankel and Soulé (1981) and Soulé (1983), I am not aware that an attempt has been made to describe even the simplest of such interactions, although population viability analysis, which models future trends on the basis of different factors at different intensities, seeks to mimic them. It does not even appear that an attempt hitherto has been made, at least as far as birds are concerned, simply to catalogue all the elements that commonly serve in the detection of extinction-proneness.

Meanwhile, since the mid-1990s we have had a widely acclaimed and approved new set of criteria for global status assessment (next section) which champions the use of quantifiable indicators, often in combination. The primary indicators (decline rate, range size and population size) are explicit; however, many secondary indicators (various types of ecological adaptation) are concealed within the general requirement that the criteria will be applied with due consideration of circumstance. The following baseline catalogue attempts to deal with both types, and is offered with three things in mind. First, it may simply be of help in identifying at an early stage the most appropriate species (on the basis of particular geographic areas, habitats, life-history strategies, and so on) for which to be most vigilant. It may also sometimes provide points of reference in cases where quantification otherwise is a matter of informed opinion and decisions to red-list depend on an arbitrary indulgence of the precautionary principle. Finally, it may act as a challenge to fieldworkers to start filling the critical gaps in our knowledge concerning the evolutionary and anthropogenic circumstances of any species suspected to be in difficulties, whether local or global.

In this essay I do not reference information taken directly from Collar and Stuart (1985), Collar *et al.* (1992, 1994), and *HBW* itself.

Distribution

Small range size

For a species to become extinct, its numbers must decline and, in some measurable way, its range size must decrease. Small range size is clearly associated, albeit unpredictably, with extinction risk (see Figure 1). In a small range, any detrimental practices may so rapidly influence the entire population of a species, however abundant it may be (Terborgh 1974), that “extinction is possible within the time span which would be required for conservation measures to take effect” (de la Mare 1987). Perhaps the most notorious example of this was the 1 km² ridge forest at Centinela near Río

Palenque in Ecuador, 10% of whose flora (some 100 species) were estimated to be unique to the site, which was pristine in 1975 and totally cleared by 1988 (Dodson and Gentry 1991). The most notorious avian example may be the Stephen Island Wren *Xenicus lyalli*, whose range was so small that a single cat is credited with its extermination (Rothschild 1907). The need to guard against such catastrophes was precisely what motivated the BirdLife exercise to identify and map "restricted-range" species (ICBP 1992, Stattersfield *et al.* 1998). These are creatures that demand our eternal vigilance, most of which needs to be directed at the distribution and intensity of habitat destruction, and in particular of forest clearance. The threshold of 50,000 km² for a restricted-range bird builds in the opportunity, in many cases, for pre-emptive conservation; conversely, the opportunity for other deleterious factors to make a serious impact escalates with diminishing range size.

Linear range

Species whose habitats are essentially linear in nature (through confinement to rivers, shorelines, etc.) are exposed to relatively elevated risks from conversion or, more usually, disruption of their habitats, and also because the one-dimensionality of their range greatly constrains total population size. Maps that generalise ranges can give a very misleading idea of the status of such species, which can appear to occupy very large areas and hence to be entirely secure. Recently it was shown that the once-abundant River Lapwing *Vanellus duvaucelii* is highly disadvantaged, in Laos at least, through its confinement to moderately large rivers (>30 m wide), which however are also foci for human settlement and disturbance, and are the persistent target for hydroelectric installations (Duckworth *et al.* 1998). Disturbance, pollution and/or siltation of rivers affect anatids like Blue Duck *Hymenolaimus malacorhynchos* and Brazilian Merganser *Mergus octosetaceus*, sandbank nesters such as Indian Skimmer *Rynchops albicollis* and Piping Plover *Charadrius melodus*, and fish-dependent forest birds like Blakiston's Eagle-owl *Bubo blakistoni*; it can even endanger small birds if they also occupy small ranges, such as the Rufous-throated Dipper *Cinclus schulzi* and Luzon Water-redstart *Rhyacornis bicolor*. Birds of riverine forest like the Wattled Curassow *Crax globulosa* suffer disproportionately if disturbance and destruction of their habitat is compounded by hunting.

Ancient isolates

Islands have been the venue for the majority of recorded avian extinctions since 1600 (King 1985). Confinement to ancient geographical features – oceanic islands, limestone caves, montane and crater lakes – represents a serious liability, owing to the fact that most of the species's evolutionary history has been spent *in situ*, without external contact. Long-term isolation is in itself a defence against the customary "continental" pressures of an evolutionarily diverse environment, so adaptations such as flightlessness and tameness in island birds are traits that have been selected *for* in the absence of predators, but which are dramatically selected *against* as soon as assisted passage allows those predators (but also aggressive competitors and habitat-altering domestic stock) to enter the equation. This type of extinction-proneness has been recognised ever since the demise of the Dodo *Raphus cucullatus*, and the scale of the disaster that convulsed the Pacific in the wake of Polynesian man (Milberg and Tyrberg 1993, Pimm *et al.* 1994, Steadman 1995) has led to the notion that many avifaunas

Figure 1. Range sizes of threatened bird species. Seventy-three per cent of threatened bird species have restricted ranges of under 50,000 km², and c.150 species have tiny ranges of under 100 km² (BirdLife International in prep.).

have already experienced an “extinction filter” (Balmford 1996). Even so, the horrifying loss of the Guam avifauna to the snake *Boiga irregularis* within the last two decades (Savidge 1987) demonstrates that there are still many constitutively defenceless species for which vigilance is needed. These are, however, very difficult cases: no matter how great the precautions, almost certainly something – very possibly disease (Diamond 1984a, Ralph and van Riper 1985) – will eventually slip through the barrier. (It is worth noting that the problem of long isolation extends to Australia, devastated as it is by rabbits, cats and foxes, with birds like the Gouldian Finch *Chloebia gouldiae* and Star Finch *Neochmia ruficauda* suffering from exotic invaders in the form of a parasitic mite and a habitat-smothering vine respectively.)

Political isolates

Confinement to one or two countries is a non-biological circumstance that nevertheless counts as a form of constitutive liability, rendering species vulnerable to the unpredictability of the political or economic environment. Civil unrest in Peru made it extremely difficult throughout the early 1990s to contemplate any intervention – external or internal – on behalf of the Junin Flightless Grebe *Podiceps taczanowskii* (a Critically Endangered ancient isolate). The persistent war within Angola has had the same effect on the rarest Scarp endemics (six listed as Endangered in *Birds to watch* 2). U.S. policy towards Cuba cuts off important potential funding for the conservation of the many threatened birds there, nine of which are unique to the country. No-one can get into northern Iraq to discover the status of bustards, or into southern Myanmar (Burma) to find out if, after over a decade of intense effort for the “last population” in Thailand, Gurney's Pitta *Pitta gurneyi* survives in the Tenasserim tracts. Cambodia, best hope for the Giant Ibis *Pseudibis gigantea*, continues to make virtual bystanders of aid workers and environmentalists. Moreover, when there is serious humanitarian work to do, even the most ardent conservationist is unlikely to feel like knocking on ministry doors; if refugees are camped on the type and only locality of the Somali Long-clawed Lark *Heteromirafr archeri*, then peace be with them. In any case, as everyone knows who has made a long habit of knocking on ministry doors, the influence of corruption in governmental organisations – unenviably underfunded while charged with regulating the exploitation of often enormously valuable resources – is all-pervasive; indeed, the role of political corruption in the erasure of biodiversity is one of those ultimate causes of extinction that cries out for exposure and analysis.

Population

Small population size

Risk of extinction increases with decreasing population size (see Figure 2). Among the forces that conspire to put small populations at increased risk are demographic stochasticity (chance events like an entire generation being the same sex), environmental stochasticity (chance events like storms and fires), genetic deterioration and social dysfunction (Simberloff 1986). The “effective” (roughly meaning breeding) population size is generally used, but many populations possess barely detectable and hence unquantifiable numbers of “floaters”, whose value as rapid substitute breeders cannot be ignored. The debate about what constitutes a minimum viable population size continues to evolve (Franklin and Frankham 1998a,b Lynch and Lande 1998), but it is apparent that some species suffer no great harm from passing through genetic bottlenecks, at least as long as the bottleneck is brief (so that most genetic variation is retained): the Seychelles Warbler *Acrocephalus sechellensis* hit a low of c.50 in 1965 (2,060 in 1997), and the Chatham Islands Robin *Petroica traversi* was down to five in 1980 (250 in 1998) (recent information *per* A. J. Stattersfield).

Population decline

Decline is a clear indicator of adversity (again see Figure 2), and both measuring and explaining decline are crucial to an understanding of the nature and mitigation of the problem. A great challenge for conservation assessment is simply to *detect* significant declines, which can be particularly difficult for species with large ranges, since early status reports (often uncritically repeated, so that they seem relatively recent) can mask modern circumstances. The Spot-billed Pelican *Pelecanus philippensis* and Greater Adjutant *Leptoptilos dubius* once had huge ranges and populations (the former purportedly in millions) focused on Myanmar (Burma), but in the past century these ranges have been “hollowed out”, leaving the pelican moderately secure only in Sri Lanka and the stork at the brink of extinction. Yet neither bird was in the second edition of the international Red Data Book (King 1978-1979); nor – in spite of Stresemann and Grote's (1943) concern, which, alas, found expression in the wrong

Figure 2. Population sizes and trends of threatened bird species. Seventy-six per cent of threatened bird species have small populations of under 10,000 individuals, and 72% are declining. More than 300 species have tiny populations of under 1,000 (BirdLife International in prep.).

language at the wrong moment (back to political isolates!) – was the now unfindable Slender-billed Curlew *Numenius tenuirostris*. These birds will not have died off – or died back – entirely in vain if only they serve as warnings to maintain the monitoring and red-listing of free-falling species like the Lesser Kestrel *Falco naumanni* and Marbled Teal *Marmaronetta angustirostris* until such time as the declines are understood and tempered. Most of all they serve simply to indicate that the regular gathering of good-quality information on the status of all species is essential to detect declines before they take on terminal characteristics.

Fragmentation

The number and size of subpopulations (difficult to judge though they often are), in particular the size and condition of the largest of them, may have a direct bearing on the fate of species and their need for management. Part of the concern is that highly sedentary species will end up in a series of essentially independent subpopulations, none of which is sufficiently large to avoid long-term effects of inbreeding (some Himalayan galliforms such as Cheer Pheasant *Catreus wallichii* and Blyth's Tragopan *Tragopan blythii* are perhaps strong avian examples). Moreover, modelling of sink/source dynamics shows that, even in more vagile species, the majority of individuals can sometimes reside in non-sustaining subpopulations (Howe *et al.* 1991). Of course the relative productivity of different subpopulations can only be discovered through long-term study of breeding success and survival, but a body of evidence is emerging that elevated predator incursion, diminished food supply and other factors conspire to render many small fragments essentially unproductive (Kattan *et al.* 1994, Turner 1996, Robinson 1998). Certain guilds of bird appear to suffer disproportionately from fragmentation, including large raptors, large canopy frugivores and large terrestrial or near-terrestrial insectivores (Terborgh and Winter 1980, Diamond 1984b).

Ecology

Habitat choice

A species's choice of habitat determines its fate. Habitat destruction is now the most important cause of extinction, responsible for 50% of continental and 20% of island bird losses (Diamond 1984a), and it is much the greatest cause of bird endangerment (Collar *et al.* 1994, 1997). However, habitats are distributed unevenly and differ in the types and levels of human pressure they endure, so the way that measures of habitat are used as indicating susceptibility will vary widely. Simply the rate of decline in some more circumscribed habitats, and simply the extent of others, is evidence enough to red-list some species, on the basis of traits already discussed. The phenomenon of extreme lowland rainforest specialism described by Wells (1985) in Malesia predicates whole suites of species with special needs. Natural patchiness may reflect camouflaged historical or ecological processes (Diamond 1980) and may in turn be camouflaged by generalised range maps, leading (as indicated above) to serious misjudgements of status. Confinement to habitat dominated by single plant species is usually better expressed as a feeding or breeding specialisation (see below), but Kirtland's Warbler *Dendroica kirtlandii*, with its remarkable summer requirement of stands of 8–20-year-old Jack Pines *Pinus banksiana*, is perhaps an exception. Habitats can, of course, be optimal, suboptimal or marginal, and their relative values can only really be identified by long-term studies of breeding success and survival rates. (Perhaps it should also be noted here that over the next century global warming can be expected to shrink many already severely reduced habitats, causing them and their species to wink out in ways over which we are, on present form, unlikely to have the slightest control.)

Indirect upshots of habitat destruction include (a) the breakdown of barriers that keep two species apart, resulting in hybridisation and, in some cases, genetic swamping of one species by the other (Australia's Black-eared Miner *Manorina melanotis* is in this kind of trouble); and (b) the disproportionate benefit it gives to certain brood parasites, resulting in small local populations of hosts suffering total reproductive failure (the Brown-headed Cowbird *Molothrus ater* now jeopardises three species, while the Shiny Cowbird *M. bonariensis* does the same, actually or potentially, for several more).

Habitat sensitivity

Complex stable communities, which generally involve a high proportion of sedentary “equilibrium” species (*K*-selected; see below), tend to simplify under stress. This is one of the great take-home messages of ecology: if a pristine ecosystem is disturbed, for example by hunting or by logging, then *some* components of that ecosystem will

suffer (Erwin 1988, Brown and Brown 1992, Johns 1997, Whitmore 1997). The widespread view that natural resources must provide economic benefits in order to win vital conservation support is often expressed in the compelling, rebarbative phrase "use it or lose it"; but the truth is that to use it *is* to lose it – some of it, anyway. The sensitivity of certain bird species – notably terrestrial and lower arboreal insectivores – to habitat modification (e.g. Lambert 1992, Thiollay 1992, Marsden 1998) needs systematic documentation, and the equilibrium of their environments must be strictly maintained: for example, protected areas within their ranges will have to be managed in such a way that large cores are kept free of human perturbation. The phenomenon of trophic simplification has been shown on land and in water; notably the loss of top predators destabilises communities by allowing the increase of smaller predators, thus causing surges and drops in numbers further down the food chain, and shaking out a number of species altogether (Terborgh and Winter 1980, Lowe-McConnell 1987, Soulé *et al.* 1988).

Seasonality

Migration increases the number of areas, habitats and food resources that a species depends on, and while, in the absence of anthropogenic influences, this predicates no greater inherent vulnerability, the risks certainly multiply when the global environment is patchily deteriorating. Migration therefore also creates a much more complex information requirement, relating to each site and stage of the annual or life cycle. Radio-tracking of Resplendent Quetzals *Pharomachrus mocinno* and other Central American montane bird species has demonstrated their unexpectedly complex patterns of habitat dependence through the year (e.g. Powell and Bjork 1994), and these findings are matched by the discovery of different habitats and strategies used by male, female and juvenile warblers over the non-breeding period (Hutto 1998). Although the problem is clearly most acute for species with already highly circumscribed ranges, even very widespread species can be compromised; I strongly suspect that the loss of the Slender-billed Curlew is attributable to loss of its staging grounds – presumably the Russian steppes – between summer and winter quarters, and equally I guess that the Eskimo Curlew *Numenius borealis* failed to recover its numbers owing to the obliteration of the prairies, which it was known to use on spring stopover. Moreover, where species form seasonal concentrations, as the Eskimo Curlew certainly did, they elevate their susceptibility by temporarily reducing their range size (see above); and where they move to areas inaccessible for political reasons, they jeopardise all the endeavours made elsewhere on their behalf.

Feeding specialisation

Feeding specialisation is a high-risk/high-return strategy. The return is that competition for the resource is minimal; the risk is that disappearance of the resource is terminal. Mistletoe specialists, like White-cheeked Cotingas *Zaratornis stresemanni* and Painted Honeyeaters *Grantiella picta*, and fig specialists, like Large Green-pigeon *Treron capellei* (Lambert 1991; see Figure 3) and Pesquet's Parrot *Psittichas fulgidus* (Mack and Wright 1998), face serious consequences if particular trees or particular tracts are cleared. Too singular a dependence on one species of palm may lie behind the disappearance of the Glaucous Macaw *Anodorhynchus glaucus*, and it certainly lies behind the critical imperilment of Lear's *A. leari*; indeed, any strong dependence on fruit or nectar represents a risk when local climate and habitat loss conspire to isolate these resources in both time and space (a fragmentation issue). The Kaka *Nestor meridionalis* needs insect-derived honeydew to bring it into breeding condition, but introduced wasps also favour this resource and are getting to it first. Rats may have removed the prey-base of the presumed extinct Snail-eating Coua *Coua delalandei*, and medieval man certainly did so with the Canarian Black Oystercatcher *Haematopus meadewaldoi*. A single pair of Siberian Cranes *Grus leucogeranus* needs miles of narrow tundra lakeshore vegetation in which to find the food to rear its single offspring (Potapov 1992); this discovery illuminates the difficulty such a *K*-selected species has in recovering from losses elsewhere in its range.

Nomadism

Nomadism is a distinctive form of food specialisation in which a species is liberated (or driven) from a geographical position for all or part of the annual cycle and then ranges erratically within often very wide limits. Such unpredictability renders conservation planning highly problematic. The Passenger Pigeon *Ectopistes migratorius* was a specialist on a food (mast) that was patchy in both space and time, and which therefore needed social facilitation (strung-out fronts of flying birds) to find suffi-

cient resources to feed and breed: despite the incredible slaughter the species endured, habitat destruction appears to be primarily responsible for its loss, since the patchier the food became, the more difficult it was for individuals to find it (Bucher 1992). Characteristics of nomadic specialisation include (a) high mobility, (b) high investment in social facilitation, (c) some degree of food specialisation, and (d) breeding opportunism. Amongst threatened birds that exhibit some of these traits are the Thick-billed Parrot *Rhynchopsitta pachyrhyncha* (a pine-seed specialist), Golden-plumed Parakeet *Leptosittaca branickii* (perhaps heavily dependent on *Podocarpus* fruits), Purple-winged Ground-dove *Claravis godefrida* and various *Sporophila* (bamboo specialists, as perhaps was Bachman's Warbler *Vermivora bachmani*).

Breeding specialisation

Hole-nesters tend to be forest and woodland climax species, making use of mature, senescent and dead trees large enough and (at least in parts) rotten enough to house them over the breeding cycle. Large-bodied birds like hornbills necessarily require massive trees; but in parts of Australia even moderate-sized species depend on extremely slow-growing eucalypts, some of which are believed to take half a millenium to reach an age at which appropriately deep splits and fissures begin to appear in their upper trunks and branches (Mawson and Long 1994). Studies on the island of Sumba in Indonesia have shown that the hole-nesting avifauna of a forest tract may entirely depend on a small number of particularly large trees, often figs (Marsden 1995). Forestry management regimes which fail to take account of these facts stand to wipe out entire groups of species. Obligate bank-nesters are also constrained: the Blue Swallow *Hirundo atrocaerulea* utilises Aardvark *Orycteropus afer* burrows and pot-holes, while the Three-toed Jacamar *Jacamaralcyon tridactyla* needs stream-hewn banks in forest remnants: both species are uncomfortably constrained by these circumstances. White-necked and Grey-necked Picathartes *Picathartes gymnocephalus* and *P. oreas* need boulders and rockfaces inside primary forest on which to build their nests, which are consequently easily and repeatedly plundered by human nest-despoilers. The Edible-nest Swiftlet *Aerodramus fuciphagus* suffers the same problem, and indeed this, along with other cave-nesting swifts and the Oilbird *Steatornis caripensis*, share with many seabirds and some megapodes, including the threatened Maleo *Macrocephalon maleo*, the inherent susceptibility of being obliged by geology and geography to form site-specific seasonal concentrations (i.e. a temporarily small range size).

Demography

The intrinsic rate of increase (r) in species affects their ability to recover; those with low reproductive rates – called “ K -selected” since they generally occur in highly stable environments whose carrying capacity (K) is permanently at its upper limit – are notably susceptible to depletion by human exploitation, typically driven by maximum profit targets without regard to the long term. Greatly deferred maturity, protracted generation length, high life expectancy and small clutch-size all predict susceptibility. Albatrosses are classic examples, and the loss of only relatively small numbers of some species to the tuna industry's longlines is causing an inexorable population decline, as rates of recruitment fail to keep pace with rates of depletion (Croxall and Gales 1998). Many other seabirds, as well as some of the larger raptors, storks, ibises and cranes, exhibit similar life-history traits that may disadvantage them in the face of direct and indirect human influences.

Economic attributes

Certain kinds of species possess characteristics whose attractiveness to man is clearly disadvantageous. Birds suffer from human over-exploitation for food, for plumes and other body-parts, and for some form of companionship. The key attributes are edibility, visual or vocal beauty, and ease of capture (sometimes also ease of maintenance); cultural and medicinal properties do not seriously figure. Of course edibility is a common condition in birds, but some species are obviously more worth pursuing than others: among the more usual targets are (a) large-bodied, easily snared species of the forest floor, and (b) sociable species such as nest in colonies (especially those tied to specific sites, which simplifies access to their eggs as well), roost in flocks, and come to decoys. For some people, inevitably, the beauty of birds is the price they can charge for them, but at least plume-hunting is now commercially extinct and the extensive hunting of birds for ceremonial adornment is largely confined to parts of the Amazon (macaws and other parrots), the Greater Sundas (hornbills) and New Guinea (birds of paradise, parrots and others); possibly the only taxa seriously endan-

gered by traditional use were in the Pacific – *Vini* lorikeets and certain Hawaiian honeycreepers. However, the cagebird trade remains a major cause of endangerment for some birds, although mainly only when in combination with habitat destruction. Vegetarian species are hugely preferred, for reasons of maintenance; within this subset, parrots are prime targets because of their colours, mimicry and domesticity. Such a combination of attributes is, however, rare in other major groups of species, many of which suffer from intense local rather than international interest (Yellow Cardinal *Gubernatrix cristata* in Argentina, Green Avadavat *Amandava formosa* in India, Straw-headed Bulbul *Pycnonotus zeylanicus* and Java Sparrow *Padda oryzivora* in Indonesia).

A system for status assessment

In the 1990s the International Union for Conservation of Nature and Natural Resources (now known as IUCN–The World Conservation Union) established formal criteria for use in evaluating the probability of a taxon becoming extinct (IUCN Species Survival Commission 1994). In the course of 1993–1994, while the criteria were still being finalised, BirdLife used them to determine the species in *Birds to watch* 2 (Collar *et al.* 1994). Thus the first and second volumes of *HBW* reflected BirdLife/ICBP use of the old IUCN criteria, as applied in the most recent Red Data Books (Collar and Stuart 1985, Collar *et al.* 1992) and the first *Birds to watch* (Collar and Andrew 1988) – this last requiring a degree of interpretation for the Asian and Pacific species since it did not attempt to allocate categories to species. Since 1994 *HBW* has been able to draw on *Birds to watch* 2, and from 2000 there will be a further and much more detailed revision which will serve thereafter as the point of reference for species status in the *HBW* accounts.

The old IUCN criteria for classifying threatened species consisted of five comfortably vague (but, with common sense, perfectly serviceable) status categories, two of which explicitly indicated probability of extinction and three of which did not. These have now been replaced with a much more demanding (but equally serviceable) set of criteria, subcriteria and qualifiers, all of which are related to three categories of threat expressing different probabilities of extinction within particular time-frames. The huge advantage of this new system is that it forces a degree of translucency and consistency into a process which previously offered shelter from these things (and therefore freedom from public accountability, something which ran the risk of bringing discredit to the entire red-listing enterprise).

The new criteria depend on the user being able to make *some* credible estimate of numerical circumstance. As noted earlier, a species can only become extinct by losing its numbers and shrinking some aspect of its range, and these are the two obvious things to measure when seeking to evaluate whether the probability of extinction is increasing for a taxon or not. So the five measurements available are: (1) high rate of population decline irrespective of overall numbers; (2) significant rate of population decline linked to range size; (3) significant rate of decline in range linked to population size; (4) three stand-alone population thresholds and a single stand-alone range threshold; and (5) a population viability analysis which predicts extinction within given time-frames.

The new IUCN criteria

After *Birds to watch* 2 went to press, the IUCN criteria were very slightly altered; and they will almost certainly be altered – adjusted – again in the near future. What follows is a brief account of the criteria as they currently stand, but fuller details can be found in the official booklet (IUCN SSC 1994) or at the following websites:

http://www.iucn.org/themes/ssc/redlist/ssc-rl_c.htm
http://www.wcmc.org.uk:80/species/animals/animal_redlist.html

The categories and criteria below are reproduced almost wholly *verbatim* from IUCN SSC (1994); they are also summarised in Table 1. Several definitions needed to interpret the criteria are appended at the end.

Critically Endangered

A taxon is Critically Endangered (CR) when it is facing an extremely high risk of extinction in the wild in the immediate future, as defined by any of the following criteria (A to E):

- A** population reduction in the form of either of
 - (1) an observed, estimated, inferred or suspected reduction of at least 80% over the last 10 years or 3 generations, whichever is the longer, based on (and specifying) any of: (a) direct observation; (b) an index of abundance appropriate for the taxon; (c) a decline in area of occupancy, extent of occurrence and/or quality of habitat; (d) actual or potential levels of exploitation; (e) the effects of introduced taxa, hybridisation, pathogens, pollutants, competitors or parasites;
 - (2) a reduction of at least 80%, projected or suspected to be met within the next 10 years or 3 generations, whichever is the longer, based on (and specifying) any of (b), (c), (d) or (e) above;
- B** extent of occurrence estimated to be less than 100 km² or area of occupancy estimated to be less than 10 km², and estimates indicating any two of:
 - (1) severely fragmented or known to exist at only a single location;
 - (2) continuing decline, observed, inferred or projected, in any of: (a) extent of occurrence; (b) area of occupancy; (c) area, extent and/or quality of habitat; (d) number of locations or subpopulations; (e) number of mature individuals;
 - (3) extreme fluctuations in any of: (a) extent of occurrence; (b) area of occupancy; (c) number of locations or subpopulations; (d) number of mature individuals;
- C** population estimated to number less than 250 mature individuals and either:
 - (1) an estimated continuing decline of at least 25% within 3 years or 1 generation, whichever is longer or
 - (2) a continuing decline, observed, projected, or inferred, in numbers of mature individuals and population structure in the form of either: (a) severely fragmented (i.e. no subpopulation estimated to contain more than 50 mature individuals); (b) all individuals in a single subpopulation;
- D** population estimated to number less than 50 mature individuals;
- E** quantitative analysis showing the probability of extinction in the wild is at least 50% within 10 years or 3 generations, whichever is the longer.

Endangered

A taxon is Endangered (EN) when it is not Critically Endangered but is facing a very high risk of extinction in the wild in the near future, as defined by any of the following criteria (A to E):

- A** population reduction in the form of either of:
 - (1) an observed, estimated, inferred or suspected reduction of at least 50% over the last 10 years or 3 generations, whichever is the longer, based on (and specifying) any of: (a) direct observation; (b) an index of abundance appropriate for the taxon; (c) a decline in area of occupancy, extent of occurrence and/or quality of habitat; (d) actual or potential levels of exploitation; (e) the effects of introduced taxa, hybridisation, pathogens, pollutants, competitors or parasites;
 - (2) a reduction of at least 50%, projected or suspected to be met within the next 10 years or 3 generations, whichever is the longer, based on (and specifying) any of (b), (c), (d), or (e) above;
- B** extent of occurrence estimated to be less than 5,000 km² or area of occupancy estimated to be less than 500 km², and estimates indicating any two of:
 - (1) severely fragmented or known to exist at no more than 5 locations;
 - (2) continuing decline, inferred, observed or projected, in any of: (a) extent of occurrence; (b) area of occupancy; (c) area, extent and/or quality of habitat; (d) number of locations or subpopulations; (e) number of mature individuals;
 - (3) extreme fluctuations in any of: (a) extent of occurrence; (b) area of occupancy; (c) number of locations or subpopulations; (d) number of mature individuals;
- C** population estimated to number less than 2,500 mature individuals and either:
 - (1) an estimated continuing decline of at least 20% within 5 years or 2 generations, whichever is longer, or

- (2) a continuing decline, observed, projected, or inferred, in numbers of mature individuals and population structure in the form of either: (a) severely fragmented (i.e. no subpopulation estimated to contain more than 250 mature individuals); (b) all individuals in a single subpopulation;

D population estimated to number less than 250 mature individuals;

E quantitative analysis showing the probability of extinction in the wild is at least 20% within 20 years or 5 generations, whichever is the longer.

Vulnerable

A taxon is Vulnerable (VU) when it is not Critically Endangered or Endangered but is facing a high risk of extinction in the wild in the medium-term future, as defined by any of the following criteria (A to E):

A population reduction in the form of either of:

- (1) an observed, estimated, inferred or suspected reduction of at least 20% over the last 10 years or 3 generations, whichever is the longer, based on (and specifying) any of: (a) direct observation; (b) an index of abundance appropriate for the taxon; (c) a decline in area of occupancy, extent of occurrence and/or quality of habitat; (d) actual or potential levels of exploitation; (e) the effects of introduced taxa, hybridisation, pathogens, pollutants, competitors or parasites;
- (2) a reduction of at least 20%, projected or suspected to be met within the next 10 years or 3 generations, whichever is the longer, based on (and specifying) any of (b), (c), (d) or (e) above;

B extent of occurrence estimated to be less than 20,000 km² or area of occupancy estimated to be less than 2,000 km², and estimates indicating any two of:

- (1) severely fragmented or known to exist at no more than 10 locations;
- (2) continuing decline, inferred, observed or projected, in any of: (a) extent of occurrence; (b) area of occupancy; (c) area, extent and/or quality of habitat; (d) number of locations or subpopulations; (e) number of mature individuals;
- (3) extreme fluctuations in any of: (a) extent of occurrence; (b) area of occupancy; (c) number of locations or subpopulations; (d) number of mature individuals;

C population estimated to number less than 10,000 mature individuals and either:

- (1) an estimated continuing decline of at least 10% within 10 years or 3 generations, whichever is longer, or
- (2) a continuing decline, observed, projected, or inferred, in numbers of mature individuals and population structure in the form of either: (a) severely fragmented (i.e. no subpopulation estimated to contain more than 1,000 mature individuals); (b) all individuals in a single subpopulation;

D population very small or restricted in the form of either of:

- (1) population estimated to number less than 1,000 mature individuals;
- (2) population characterised by an acute restriction in its area of occupancy (typically less than 100 km²) or in the number of locations (typically less than 5);

E quantitative analysis showing the probability of extinction in the wild is at least 10% within 100 years.

Lower Risk

A taxon is Lower Risk (LR) when it has been evaluated and does not satisfy the criteria for any of the categories Critically Endangered, Endangered or Vulnerable. Taxa included in the Lower Risk category can be separated into three subcategories:

- (1) *Conservation Dependent* (cd) – taxa which are the focus of a continuing taxon-specific or habitat-specific conservation programme targeted towards the taxon in question, the cessation of which would result in the taxon qualifying for one of the threatened categories above within a period of 5 years;
- (2) *Near Threatened* (nt) – taxa which do not qualify for Conservation Dependent, but which are close to quali-

Type of criteria	Main criteria	Sub-criteria	Qualifiers	Codes	
A. RAPID POPULATION DECLINE	Decline >80% in 10 years or 3 generations (CR) involving either 1 or 2:	1. Decline which has happened (observed, estimated, inferred or suspected) based on a-e opposite:	a. Direct observation	A1a	
			b. Index of abundance	A1b	
			c. Decline in extent of occurrence, area of occupancy, and/or quality of habitat	A1c	
			d. Actual or potential levels of exploitation	A1d	
	Decline >50% in 10 years or 3 generations (EN) involving either 1 or 2:		e. Effects of introduced taxa, hybridisation, pathogens, pollutants, competitors or parasites	A1e	
	Decline >20% in 10 years or 3 generations (VU) involving either 1 or 2:	2. Decline likely in near future (projected or suspected) based on b-e opposite:	b. As b above	A2b	
			c. As c above	A2c	
			d. As d above	A2d	
		e. As e above	A2e		
B. SMALL RANGE fragmented, declining or fluctuating	Extent of occurrence estimated <100 km² (CR) with any two of 1,2 or 3:	1. Severe fragmentation or	None	B1	
	Extent of occurrence estimated <5,000 km² (EN) with any two of 1, 2 or 3:				At 1 location (CR)
	Extent of occurrence estimated <20,000 km² (VU) with any two of 1, 2 or 3:				At <5 locations (EN)
	or	2. Continuing decline (observed, inferred or projected) in any of a-e opposite:	At <10 locations (VU)		
			a. Extent of occurrence	B2a	
			b. Area of occupancy	B2b	
			c. Area, extent and/or quality of habitat	B2c	
			d. Number of locations or subpopulations	B2d	
	Area of occupancy estimated <10 km² (CR) with any two of 1, 2 or 3:	3. Extreme fluctuations in any of a-d opposite:	e. Number of mature individuals	B2e	
	Area of occupancy estimated <500 km² (EN) with any two of 1, 2 or 3:		a. Extent of occurrence	B3a	
	Area of occupancy estimated <2,000 km² (VU) with any two of 1, 2 or 3:		b. Area of occupancy	B3b	
			c. Number of locations or subpopulations	B3c	
		d. Number of mature individuals	B3d		
	C. SMALL POPULATION & DECLINING	Population <250 mature individuals (CR) and either 1 or 2	1. Decline >25% in 3 years or 1 generation (CR) Decline >20% in 5 years or 2 generations (EN) Decline >10% in 10 years or 3 generations (VU)	None	C1
Population <2,500 mature individuals (EN) and either 1 or 2		2. Continuing decline in numbers of mature individuals and population structure (observed, projected or inferred) in form of either a or b opposite:	a. Severe fragmentation: all sub-pops<50 (CR) Severe fragmentation: all sub-pops <250 (EN) Severe fragmentation: all sub-pops <1,000 (VU)	C2a	
			b. All individuals in a single sub-pop	C2b	
Population <10,000 mature individuals (VU) and either 1 or 2					
D1. VERY SMALL POPULATION	Population <50 mature individuals (CR)	None	None	D1	
	Population <250 mature individuals (EN)				
	Population <1,000 mature individuals (VU)				
D2. VERY SMALL RANGE	Area of occupancy <100 km² or <5 locations (VU only)	None	None	D2	
E. POPULATION VIABILITY ANALYSIS	Probability of extinction in the wild is >50% in 10 years or 3 generations (CR)	None	None	E	
	Probability of extinction in the wild is >20% in 20 years or 5 generations (EN)				
	Probability of extinction in the wild is 10% in 100 years (VU)				

fy for Vulnerable; (3) *Least Concern* (lc) – taxa which do not qualify for Conservation Dependent or Near Threatened.

Data Deficient

A taxon is Data Deficient (DD) when there is inadequate information to make a direct, or indirect, assessment of its risk of extinction based on its distribution and/or population status. A taxon in this category may be well studied, and its biology well known, but appropriate data on abundance and/or distribution are lacking. Data Deficient is therefore not a category of threat or Lower Risk. Listing of taxa in this category indicates that more information is required, and acknowledges the possibility that future research will show that threatened classification is appropriate.

Not Evaluated

A taxon is Not Evaluated (NE) when it has not yet been assessed against the criteria.

Further definitions

The following terms require definition in relation to the above: *population*, the total number of individuals of the taxon (expressed as mature individuals only); *subpopulation*, geographically or otherwise distinct groups in the population between which there is little genetic exchange; *generation*, the average age of parents in the population; *extent of occurrence*, the area contained within the shortest continuous imaginary boundary which can be drawn to encompass all the known, inferred or projected sites of present occurrence of a taxon; *area of occupancy*, the area within its extent of occurrence which is occupied by a taxon (usually only measurable in terms of the area of its habitat); *location*, a geographically or ecologically distinct area in which a single event will soon affect all individuals of the taxon present.

The problems of data quality and consistency of judgement

The new IUCN criteria are analogous to a piece of legislation: no matter how clear, objective and straightforward they are intended to be, the options and qualifications they possess, in their attempt to cater for different biological and heuristic circumstances, mean that their *consistent* application using anything less than high-quality data is unattainable. Minor loopholes and grey areas allow scope for various interpretations and hence result in variable assessments (Stattersfield 1997).

The fundamental problem is that, despite the ornithological knowledge base being so much broader than it was 25 years ago (enough to write a *Handbook* entry on every bird), it is still insufficient to sustain confident judgements on the conservation status of a significant minority of tropical species. It is not just that there are very few species for which the exact number of individual specimens alive is known, or the exact range. It is also, far more problematically, that assessments of the severity of threats to species, most obvious among them being rates of habitat loss, are commonly (a) out of date, (b) difficult to interpret, (c) incomplete, (d) unquantified, (e) patently unreliable – and any of the foregoing in combination – or otherwise (f) non-existent. Writing this at the start of 1999, I still have no clear idea of what happened in Borneo in the recent notorious fires of 1997–1998, yet the inclusion or exclusion of several Bornean endemic bird species from *Threatened birds of Asia* hangs on *some* understanding of the resultant status of the island's once-extensive forests.

Aside from the birds, which are all reviewed by staff at BirdLife International working with bird specialist groups, species status assessments are generally undertaken by individual specialists on particular groups of animals and plants; but these people are not, and cannot be expected to be, specialists on the status of their species' habitats. It is inevitable that different evaluators will use different background information (not only on threats but also on conservation measures) owing to differences (a) in the accessibility of resource material, (b) in the diligence with which they seek it, and (c) in the interpretation they place on it. For example, in a circumstance where four primary-forest species have the same range, the granting of a logging concession within that range might produce the following responses among four different evaluators:

- A assumes that the concession spells disaster, and classifies CR;
- B believes that it will take a decade to implement, and classifies EN;
- C knows that it is on such difficult terrain that extraction will be modest, and classifies VU; while
- D misses the story altogether, and classifies LR.

In a similar way, differences in panic and information levels over the recent fires in Borneo will doubtless cause equivalent disparities amongst the multiplicity of specialists assessing the conservation status of the island's endemics.

Background (i.e. non-specialist) information can thus be crucial to the red-listing of a species. Moreover, an even treatment of *all* taxa – i.e. *between* evaluators – is essential if there is then to be an equitable distribution of resources to support those taxa as a consequence of their red-listing: it is clearly unsatisfactory that misclassifications based on negligent research can qualify undeserving taxa for – and disqualify deserving taxa from – conservation support. No less importantly, therefore – and this is one of the main reasons for and advantages of Red Data Books as against Red Lists – the background information used in an evaluation needs to be stated, otherwise the entire process remains opaque. This is not just a matter of honesty, for if all that is published is the notation (e.g. VU C2b, a single declining population of under 10,000), then it can easily be assumed by later workers that the population figure is based on hard fact when all it represents is a highly precautionary inference using very slight evidence (Stattersfield 1997).

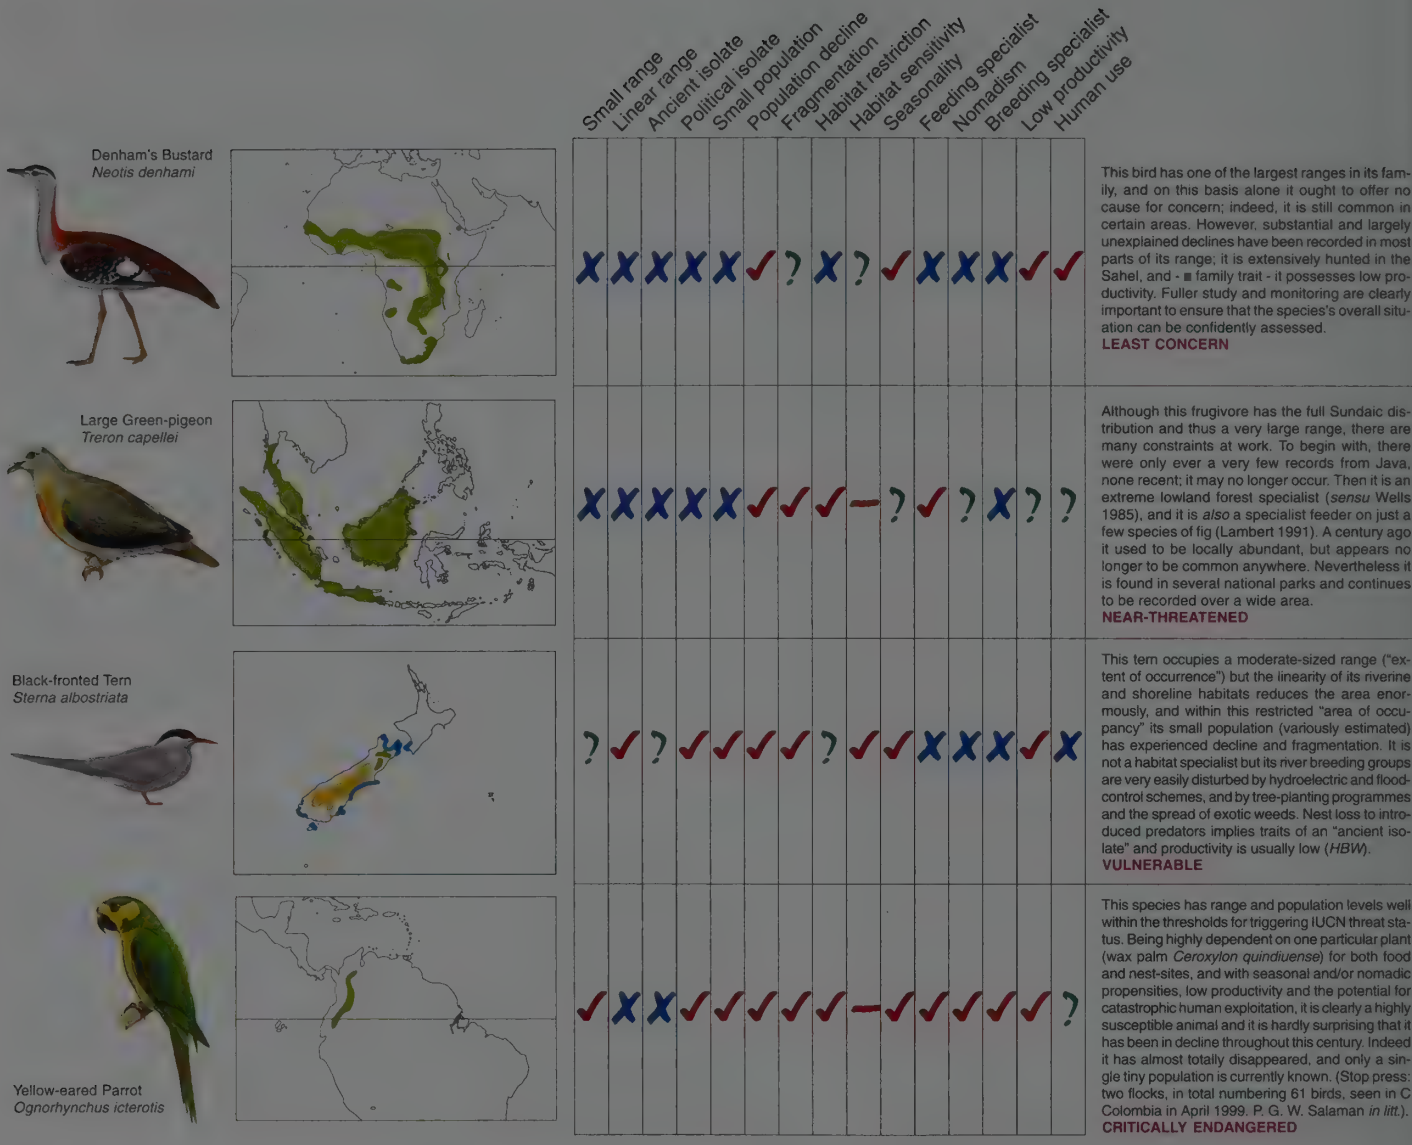

The preamble to the new IUCN system encourages evaluators who find themselves in a data vacuum to “make intelligent inferences” about the taxon they are assessing, and to “apply the precautionary principle” in a credible manner. In practice, of course, the degree of variation in actual or notional estimates relating to the criteria can be so great that what is “intelligent” or “credible” is impossible to decide. The *Birds to watch 2* team coined the term “responsible pessimism” in an attempt to deny the use of the worst-case scenario in making a decision, and to reduce default use of the category “Data Deficient”. Even so, there is always the haunting fear that to go for any more comforting scenario is to risk both complacency and opprobrium, and I strongly suspect that this is a common experience among evaluators, who would far rather be ridiculed for listing a safe species than be vilified for omitting a struggling one.

Perhaps the most problematic aspect of the classification process lies in the significance to be attached to human intervention in its various forms. The category of “Conservation Dependent” was introduced because the degree of active protection a species enjoys cannot be ignored as a determinant of its status, yet the actions taken may not be adequate or appropriate, and even if they are they may not remain so. Governments cut funding to programmes; protected areas are degazetted or simply overrun; projects mistake the causes of the problem they are tackling. In addition, there is real difficulty in assessing the overall relevance and impact of intervention when it affects only relatively small parts of the total range or population of the species; and, for example, over whether species whose ranges are wholly encompassed by protected areas, and which face no threat within them, merit listing at all. These are persistent difficulties which can only be resolved on a case-by-case basis, yet for which consistency of judgement between cases is vital.

Prospects

All risk indicators help identify threatened species, but those that are quantifiable are in a sense more relevant: these are the primary indicators that have been accessed as criteria in the new IUCN system. The ecological attributes are secondary indicators which, by not being measurable in space (ranges) or by numbers (populations), remain essentially more speculative and anecdotal. Nevertheless they have a distinct value in pointing to the kind of species to be considered for red-listing, and in justifying a final decision on categorisation in the absence of more formal numerical data (see Figure 3).

Growth in the composition of Red Lists provides some evidence for the way in which the world is coming to an end – perhaps not a literal end, but the end of an era to be sure. The year 2000 is a ridgetop from which the planet's lovers of wild places can look back at a rich landscape haunted by wasted opportunities, and peer forward at a dustbowl signposted with wasted words, “biodiversity” prime among them. But there can be no turning back, and indeed the next few decades – which means, pretty much, the rest of our lives – will be decisive for the wildlife of the planet for the next few millennia. So if we want the decidedly crumbly future to be worth the walk, we have to set about the pursuit of information and, in direct consequence, the pursuit of conservation, with an altogether new and messianic intensity. There is no reason why this needs to be left to professionals; amateurs can (and do) make a huge difference. The latitude necessarily given over to guesswork and assumption in IUCN status assessments is far too great, but even for the species that are *not* red-listed there are gaping holes in our knowledge which we cannot afford to leave unaddressed for much longer.

Naturally enough it is the threatened species on which we need to focus the maximum effort in generating new data and in implementing sound measures. The BirdLife Red Data Books have been written for people seeking to help with these species, and over the years many fieldworkers, amateur and professional, have taken up individual cases and groups of cases at given sites. For all the other species there is no better single guide to the general state of our knowledge than the *Handbook of Birds of the World*. Many of the primary indicators are discernible in the status sections provided and from the maps, and often the secondary indicators – feeding and breeding specialisations, seasonality, nomadism, demography and exploitation levels – are also accounted for in such a way as to be helpful to the evaluator. So in spite of my disquiet at the means by which our knowledge will be obtained, of course I welcome each new volume of *HBW*, and I look forward to the time when it becomes the hard-copy database for all the world's birds. If that database duly grows broader as a consequence of the individual efforts of *HBW*'s purchasers and readers, then we shall have still more reason to be grateful.

However, the single most important perception that follows from the criteria and, in particular, the catalogue is that the majority of extinction-prone species can only be secured by protected areas, many of them large, many of them strict; only, in other words, by setting aside significant tracts of the planet with the full intention that the factors rendering their inhabitants extinction-prone shall be absolutely minimised. It is futile to pretend that this can always happen, of course, and in already "over-developed" regions like western Europe there are inevitable compromises to be made over multiple uses of the landscape. Equally, however, it is futile to pretend that man and

Figure 3. Four examples of threat assessment and the value of supplementary consideration of risk indicators.

✓ = Yes X = No
? = Maybe - = Unknown

biodiversity are more than modestly compatible bedfellows, for the fate of the great majority of species is directly related to the levels of disruption and destruction inherent in modern human economic activity. Biodiversity is like the Lascaux cave art: the more contact we have with it, the quicker it dissolves away (use it: lose it). So if conservationists, planners, development agents and politicians – the people who most often invoke the term “biodiversity” – *really* want to honour its meaning, then they must understand that their primary responsibility is to defend key areas – and, I repeat, *large* areas – of land and sea from the gross intrusions of the species to which they belong.

Not, of course, that even this will be enough. For protected areas to survive for more than a generation or two, a genuine revolution is needed in human socio-economic activity and relations, involving among other things the integration of conservation interests and practices across even the least natural, most brutalised landscapes. It is an awesome prospect, but one we cannot shrink from: if the green agenda seems never-ending, this is only because we want life on earth to be that way, too.

Introduction to Volume 5

As ever, readers are referred to the general introduction to the whole HBW series, which appeared in Volume 1 (pages 15-33), while further points of possible interest may be found in the brief introductions to Volumes 2-4.

The trend set in preceding volumes, with each time more plates, more figures illustrated, and more photos published per volume has continued. We trust that this trend meets with our readers' approval, even if it provokes the alarm of the publisher! The two larger families in this volume are backed by over 100 photos each, thus permitting ample coverage of a good range of species. Another new record within the series is that for the length of a single species account: few will dispute that the much-studied cosmopolitan Common Barn-owl (*Tyto alba*) is as good a candidate as any for this award.

As anticipated in the previous volume (see Volume 4, page 26), and in response to readers' letters, it has been decided that the details on restricted-range species and their presence in Endemic Bird Areas are well worth including for the species in question. As defined by BirdLife International, a "restricted-range species" is one which in historical times has had an overall range of under 50,000 km². An Endemic Bird Area (EBA) is an area within which the nearby or overlapping ranges of two or more restricted-range species are wholly encompassed. Restricted-range species account for some 27% of the world's avifauna, or about 2600 species, and these are restricted to about 220 EBA's, which in turn support roughly 75% of all globally threatened bird species. These are thus areas of high priority for conservation, all the more so as they tend equally to be centres of endemism for other life forms.

In recent years BirdLife's data-base has been expanding rapidly towards a situation in which it is possible to give an ever more accurate status assessment for every single one of the world's bird species, as laid out in the Foreword to this volume. It is hoped that from Volume 6 onwards it will be possible to apply these new, more precise categories for all species.

One of the difficulties in producing a global handbook is that within the same language meanings and usage vary in different parts of the world. For example, in some parts of the world height above sea-level on land is commonly referred to as "elevation", whereas "altitude" is considered to refer to height above the ground in mid-air. In contrast, in other regions, "altitude" is used for both concepts; or both words are used indifferently for both concepts; or the meanings given above may, if anything, even be reversed. For the purposes of HBW the two words are used indifferently.

In the same vein, in some parts of the world the hyphenation of bird group-names involves capitalizing the initial letter of the second word in some, but not all, cases (e.g. Barred Owllet-Nightjar). In other regions, or amongst other ornithologists within the same region, it is common practice for the hyphen to be followed invariably by a

small-case letter (Barred Owlet-nightjar). Further versions of the same that are commonly used in different parts of the world involve omitting to use hyphens at all, either keeping the two words separate (Barred Owlet Nightjar) or uniting them (Barred Owletnightjar). Each of these systems has its defenders and detractors, its advantages and disadvantages, but in our opinion none of them is intrinsically "correct" or "incorrect". Within any one publication, however, it is clearly highly desirable to stick consistently to one of the available options. For the purposes of HBW, it was decided to follow the second of the abovementioned methods, in part because this is the system used by BirdLife International, amongst others; for a summary of some of the arguments in favour of this system, see Andrew (1992) *The Birds of Indonesia: a checklist (Peters' sequence)*.

While on this subject, it may be worth underlining that, despite the many major advances in the field of taxonomic study in recent decades, there are few real certainties. Taxonomy is a science of approximation, in which personal subjective opinions are permanently at work. For this reason, relatively few questions can ever be considered definitively settled, as different students commonly apply different criteria.

A couple of notes are necessary regarding the plates. First, in those plates to which it is applicable, the printed scale refers to the "normal" full figures, not to the reduced-scale flying birds, as, for example, in *Stéatornithidae* and *Caprimulgidae*. Second, following standard practice in bird books, the hummingbirds have been painted with most of their iridescent colouring fully visible. In life, because visibility of the colours depends on the angle of incidence, it is essentially impossible for all the colours to be seen by an observer at any one instant, but for the purposes of producing informative plates, this "standard" degree of artistic licence has been repeated for the present volume.

As before, the accepted French, German and Spanish names come from the sources indicated in Volumes 1 and 2. Missing names were again supplied by the relevant committees. Normand David very kindly took over correspondence regarding French names after the sad death of his predecessor, Henri Ouellet. Peter Barthel has continued cheerfully to deal with our problems regarding German names. The list of recommended Spanish names continues to be published periodically, the last batch appearing in *Ardeola* 45(1): 87-95.

Acknowledgements

As each volume goes by, the assistance we have to seek at museums appears to increase! Amongst our most important ports of call have again been the British Museum of Natural History at Tring (Robert Prys-Jones, Peter Colston, Michael Walters, Mark Adams, Cyril Walker) and the American Museum of Natural History in New York (George Barrowclough, Mary LeCroy, Paul Sweet, Allison Andors, Maria Rios), and also extremely important for the present volume have been the Louisiana State University Museum of Natural Science (Van Remsen, Steve Cardiff) and the Colección Phelps de Venezuela (Miguel Lentino); we are most grateful for all the help we have received at these institutions. We should also like to extend our particular thanks to the Field Museum in Chicago (David Willard), the Museum of Comparative Zoology in Harvard (Alison Pirie, Ernst Mayr, Raymond Paynter), the National Museums of Scotland in Edinburgh (Bob McGowan), the Sociedad Audubon de Venezuela (Clemencia Rodner, Mary Lou Goodwin, David Ascanio), the Natuurhistorisch Museum at Leiden (René Dekker), Liverpool Museum (Tony Parker), the Royal Museum of Central Africa at Tervuren in Belgium (Michel Louette), the University of Kansas Natural History Museum (Andrew Townsend Peterson) and the Natural History Museum of Los Angeles County (Kimball Garrett). We are particularly grateful to Peter Alden, who put himself to considerable trouble in order to take important photos for us at the Harvard collection.

Once again many libraries have made very important contributions to the volume. We should like to make special mention of Effie Warr of the British Museum of Natural History at Tring for her kind assistance throughout, in searching out countless papers and checking many references for us. We are also much indebted to the Museu de Zoologia of Barcelona (María Angeles Iglesias), the Sociedad Española de Ornitología in Madrid (Blas Molina) and the Estación Biológica de Doñana (José Cabot). Assistance with bibliographical references was also gratefully received from Raül Aymí (Grup Català d'Anellament), Andrés Bosso (Asociación Ornitológica del Plata), Eugenio Coconier (AOP), Stephen Debus, Anne-Marie Hinds (*Birds of North America*), Manuel Plenge, Thane K. Pratt, Ian Rowley (*Emu*) and Walter H. Weber (*Bol. SAO*). The references of scientific descriptions once again presented a number of problems,

and in addition to the sterling work of our Consultant, Walter Bock, we should like to thank Murray Bruce, Normand David, Alan Knox, Mary LeCroy, Miguel Lentino and Van Remsen for their help.

The present volume has benefited greatly from the generous input of many individuals. We are extremely grateful to Pamela C. Rasmussen, who readily lent us a great deal of her own personal photographic material to help with the plates, furnished us with a wealth of advice and unpublished data, and also refereed texts, much of this in connection with the complicated assemblage of Old World *Otus* owls. Guy Tudor has very kindly continued to lend us large numbers of photographs from the collection he has amassed over the years, and we offer him our grateful thanks. Michael Walters most generously sent us a manuscript of his unpublished monograph on the family Trochilidae, and in addition checked several scientific references. Jon Fjeldså, René-Marie Lafontaine and Mark Robbins all very kindly sent us reference material and information about newly discovered owl taxa that they have been working on. Once again, we are much obliged to the Royal Australasian Ornithologists Union and the editor of HANZAB, Peter Higgins, for generously sending us an advance copy of the proofs of their recently published Handbook.

We should also like to offer our hearty thanks to those who helped in diverse ways, for instance by refereeing texts, giving advice, or providing us with useful information, much of it unpublished; we would particularly mention Peter Browne, Rob Clay, Charles T. Collins, Stephen Debus, Geoffrey Field, Phil Gregory, Farah Ishtiaq, Alan Kemp, Ben King, Manuel Marín, Juan Mazar Barnett, Christopher Perrins, David Snow and Yuan-Hsun Sun. For their very useful advice on some long-term aspects of the project, we are very grateful to Nigel Collar, Stephen Debus, Peter Higgins, Alan Poole, Ian Rowley, Barry Taylor and Mike Wilson.

We are indeed fortunate to be able to continue benefiting from our agreements with VIREO at the Academy of Natural Sciences in Philadelphia (Doug Wechsler), and with the National Sound Archive of the British Library (Richard Ranft). We are also very grateful to Paul Coopmans, Rose Ann Rowlett (Field Guides) and Barry Walker (Manu Expeditions), who freely provided much information to help us in the planning of some projected fieldwork. Considerable efforts have been made to include the maximum information possible in the credits of each photo, and in this process agencies and individual photographers alike have been most co-operative.

The various authors and artists involved in the volume would like to thank many of the institutions already listed above, but also the Academy of Natural Sciences in Philadelphia, the Library of the Australian Museum in Sydney, the Museu Paraense Emílio Goeldi, the New Forest Owl Sanctuary (Bruce Berry) and the Vogelpark Walsrode (Dieter Rinke). Their grateful thanks also go to Mark Adams, David Agro, David Alker, Pepe Álvarez, Allison Andors, J. Phillip Angle, Luiz dos Anjos, Mick Bagley, Richard C. Banks, Luis F. Baptista, Peter-René Becker, B. M. Beehler, Bob Behrstock, Emma Bennet, M. L. Birch, Walter Bock, Walter Boles, Jon Braggs, Wolf W. Brehm, Heike Brieschke, R. M. Brigham, Dan Brooks, Robb Brumfield, Jon Cantelo, Steve W. Cardiff, Becky Chantler, Elaine Chantler, Heather Chantler, Jack Chantler, Carla Cicero, Tony Clarke, Rob Clay, Brian Coates, Nigel Collar, Charles T. Collins, Joanne Cooper, Paul Coopmans, René Corado, Stephen Debus, René Dekker, Ron Demey, Kenneth P. Dial, Rod Elgar, Gonçalo Elias, Peter English, Lincoln Fishpool, Sylke Frahnert, C. B. Frith, Kimball Garrett, Luiz Gonzaga, Gary Graves, Suzanna Greenland, Ralph J. Guitierrez, Jürgen Haffer, David Hall, Andy Hanby, Anne Hawker, Richard Heading, Christopher Helm, Sebastian Herzog, Gene K. Hess, Janet G. Hinshaw, Ian Hodgson, David Hollands, Hans Hudde, H. D. Jackson, Olaf Jahn, Nigel Jarman, Ned Johnson, Scott Johnston, Leo Joseph, Allan Keith, Elisabeth Kietzmann, Lloyd Kiff, Andrea Klug, Claus König, Katja Kunz, Mathieu Lecorre, Mary LeCroy, Marlies Leutfeld, Bradley C. Livezey, Skye Loyd, Denize Machado, Alberto Madroño, Sjoerd Mayer, Gerald Mayr, Ian McAllan, Tony Mobbs, Cécile Mourer-Chauviré, Eberhard Mussler, K. Naoki, Clas M. Naumann, B. Nicolai, John O'Neill, Storrs L. Olson, David Oren, Gertrud Osten, Fernando Pacheco, Raymond A. Paynter, Lothar Peikert, Christopher Perrins, Dieter Stefan Peters, Alison Pirie, Doug Pratt, Thane K. Pratt, Roland Prinzinger, Robert Prys-Jones, Pamela C. Rasmussen, Nigel Redman, Josef H. Reichholf, Van Remsen, Swen C. Renner, Robert Ridgely, Mark B. Robbins, Ian Rowley, Phil Rye, Paul Salaman, Julio Sánchez, Marcela Santamaria, Kathrin M. Schuchmann, Gertrud Schuchmann-Wegert, Tom Schulenberg, Colin Shawyer, Adrian Skerret, Alexander Skutch, D. Smith, Gary Stiles, Becky Stoneham, Doug Stotz, Ewa Szpala, Mike Tarburton, Don Taylor, Ulrich Tigges, Angela Turner, Armando Valdés-Velásquez, Géraldine Veron, François Vuilleumier, Cyril Walker, Michael Walters, Effie Warr, David Wege, C. M. White, Bret Whitney, Andrew Whittaker, David E. Willard, Nicholas Williams, Raffael Winkler, Manfred Wittmann, Ulrike Wittmann, Dillon Wrathall and Kristof Zyskowski. The author of Caprimulgidae would like to

reiterate his thanks to all those listed on pages 11-12 of his recent monograph, Cleere (1998).

We thank Arnau Bonan and Núria Guitart for their help in processing individual bibliographies. Our warm thanks go to Christine Barthel and Diane Willis, who worked on a variety of French and German translations. For help in a great variety of ways, we are extremely grateful to Maria Josep de Andrés, Ventura Boluda, Dolors Buxó, John Cancalosi, Juan Antonio Cantí, Esther Carrasco, Raimon Fransoy, Fortunato Frias, Oriol Frias, Sònia Frias, Ricard Gutiérrez, Yann Hermieu, Bill Kimber, Georges Lenglet, Rosa Llinàs, Isabel Martínez, Jordi Martínez, Rafael Martínez, Albert Martínez-Vilalta, María Teresa Obiols, Rob Pople, Mary and Jim Ramsay, Richard Thomas and Aurea Vilalta. Once again, we are pleased to thank Toni Llobet for the illustration on the back cover.

Sadly, one of the authors of the present volume, Betsy Trent Thomas, died some time before its publication. Betsy was author of two families in Volume 3, as well as the one in Volume 5, and she had already started work on another for Volume 6. In our correspondence, she was always most enthusiastic and encouraging about the series; we are very sorry she did not live to see its completion.

Order STRIGIFORMES

Class AVES
Order STRIGIFORMES
Family TYTONIDAE (BARN-OWLS)

- Large-headed owls with heart-shaped facial disc, long legs and strong feet, usually with well-developed talons; plumage generally brown through buff and cream to white, spotted, speckled or barred.
- 23-57 cm.

- Almost cosmopolitan.
- Wide variety of habitats, from dense forest to desert, as well as urban landscapes and towns; from cool temperate zone to tropics, and from sea-level up to c. 4000 m.
- 2 genera, 16 species, 63 taxa.
- 5 species threatened; none extinct since 1600.

Systematics

For over two centuries, taxonomists have debated whether owls should be considered closely related to diurnal birds of prey (Falconiformes) or to nightjars and their allies (Caprimulgiformes). The hooked bill for tearing flesh and the strong feet and claws for capturing prey were significant in aligning owls to birds of prey, while their larger eyes, soft plumage and other adaptations to nocturnal hunting put them closer to caprimulgiforms. Yet, while now long accepted as being closer to the Caprimulgiformes and usually placed near this order, the evidence so far is not absolutely conclusive.

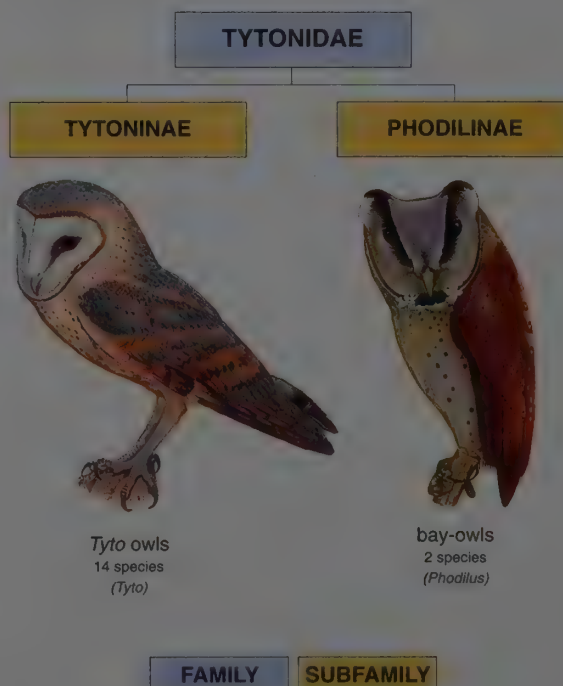

The review of owl classification by C. G. Sibley and J. E. Ahlquist in their 1990 work on DNA-DNA hybridization demonstrated this shift in opinion towards closer affinities with the Caprimulgiformes since the work of M. Fürbringer, H. von Gadow and F. E. Beddard in the late nineteenth century. Sibley and Ahlquist concluded their studies by combining the Caprimulgiformes with the owls in an expanded Strigiformes. In contrast, subsequent studies, including a report on allozyme divergence by E. Randi and colleagues in 1991, supported the traditional separation of Strigiformes from Caprimulgiformes.

A better understanding of the evolution and diversity of owls has emerged from the fossil record during the late 1980's and 1990's. At least six families are recognized, dating back to the Paleocene, up to 65 million years ago, with a major radiation taking place at least by the Eocene. From the Eocene, Oligocene and Lower Miocene deposits at Phosphorites du Quercy, in France, C. Mourer-Chauviré reviewed available material in 1987 and recorded two (later three) families. Tytonidae is represented by five genera and nine species: *Necrobyas* with five species; and four monotypic genera, namely *Nocturnavis*, *Palaeobyas*, *Palaeotyto* and *Selenornis*. *Palaeoglaux*, included with Tytonidae in 1987, was separated as *Palaeoglaucidae* when an additional species was described from Germany in 1992 and considered to show a mix of tytonid and strigid characters, as was the new family *Sophiornithidae* in 1987.

The diversity of Tytonidae in the Paleogene epochs (Paleocene, Eocene, Oligocene) is notable. With strigid owls first recorded in the Lower Miocene of Europe and North America, the evidence suggests that, along with the Tertiary radiation of small mammals, the diversification of owls increased through the Neogene epochs (Miocene, Pliocene), but with Strigidae generally superseding Tytonidae. The Quercy material represents two

extinct subfamilies of Tytonidae, *Necrobyinae* and *Selenornithinae*, sharing characters found in both *Tyto* and *Phodilus*. The genus *Necrobyas* is likened to *Tyto*, but with shorter and heavier legs. A succession of four of the species of *Necrobyas*, *N. rossignoli*, *N. harpax*, *N. edwardsi* and *N. arvernensis*, is represented from the Upper Eocene to the Lower Miocene, with an increase in size and a lengthening of the tarsometatarsus.

The genus *Tyto* dates at least to the Middle Miocene, with most of the dozen or so fossil species found in Pleistocene or Recent (Holocene) sites. The Common Barn-owl (*Tyto alba*) is known from sites dating back to the Pleistocene in Europe, Israel, and North and South America; the Ashy-faced Owl (*Tyto glaucops*) from Recent sites in the Dominican Republic; and possibly the Manus Masked-owl (*Tyto manusi*), or the Australian Masked-owl (*Tyto novaehollandiae*), or an undescribed species,

Subdivision of the Tytonidae

[Figure: Mark Hulme]

The classic feature of a barn-owl is its unique heart-shaped facial disc. This is possessed by all members of the family and instantly separates them from the "true owls" of the family Strigidae. The genus *Tyto* shows this character fully, the disc being very obvious and its shape almost perfectly that of a heart. The facial disc of the two *Phodilus* species is less markedly heart-shaped but is, nevertheless, highly distinctive.

[*Tyto alba alba*,
Perthshire, Scotland.

Planet Earth]

from Recent sites in the Bismarck Archipelago, off north-east New Guinea. Two sites have demonstrated an insular radiation of three size classes: the late Miocene of the Gargano Peninsula, Italy, formerly separated from the mainland, with *T. sanctialbani*, *T. robusta* and *T. gigantea*; and the late Pleistocene of Cuba, with *T. alba*, *T. noeli* and *T. riveroi*. In each case the first is the size of the extant Common Barn-owl, the second much larger, and the third gigantic. These size classes correlate with gigantism of mammals on islands, notably Cuba, where other giant fossil raptors are known, including a giant strigid owl. Fossil *Tyto* species elsewhere are generally much larger than the Common Barn-owl, for example *T. balearica* of Pliocene and Recent sites in Spain and France, *T. pollens* from the late Pleistocene of the Bahamas, and *T. ostologa* from the late Pleistocene of Haiti. In fact, *T. pollens*, *T. ostologa* and *T. noeli* appear to have been closely related insular counterparts. The Recent *T. cavatica* of Puerto Rico is probably closely related to the Ashy-faced Owl, and together these two represent part of an earlier radiation of taxa allied to the Common Barn-owl. *T. letocarti* from a Recent New Caledonian cave site may be generically separable from *Tyto*. However, fossil material from the Mascarene Islands that was formerly attributed to an extinct *Tyto* species is now considered to be unrelated.

The recent work on fossil material is further support for the division of living owls between the families Tytonidae and Strigidae, with the bay-owls (*Phodilus*) best placed with Tytonidae, though forming a distinct subfamily, Phodilinae. The separation of *Tyto* and *Phodilus* from other owls began in 1840 with the pterylographic studies of C. L. Nitzsch, who combined both forms in his genus *Hybris*. However, while separation of *Tyto* species as a family or subfamily has seldom been in doubt, the position of *Phodilus* has been open to question. Both F. E. Beddard in 1890 and W. P. Pycraft in 1903 considered *Phodilus* to be nearer to strigid owls, based on pterylography, osteology and other characters. A study of the syrinx in 1965 by A. Miller also considered *Phodilus* to be nearer Strigidae and not intermediate. In 1966, J. T. Marshall reviewed data on the skeleton, syrinx, voice, facial disc, ectoparasites and behaviour of *Phodilus*. He considered these characters to show departures from both Strigidae and Tytonidae without being clearly intermediate, and proposed recognition of a separate family, Phodilidae. The trend

of subsequent studies, ranging from behaviour to karyotypes, DNA-DNA hybridization and allozyme divergence, among others, is to support a Tytonidae family including *Phodilus*. By contrast, in a 1977 study of the evolution of bilateral ear asymmetry, R. A. Norberg supported the separation of *Tyto* from other owls but was uncertain about its affinity to *Phodilus*, and he considered their ear characters to have evolved independently.

Diagnostic characters of Tytonidae include a conspicuous facial ruff forming a heart-shaped disc, complete in *Tyto*, incomplete on the forehead and neck in *Phodilus*; an elongated and compressed bill; long legs, with feathers on the posterior side of the tarsus pointing upwards (*Tyto*) and feathered throughout (*Phodilus*); the inner toe as long as the middle toe, with the claw of the latter pectinated; the tenth, outermost, primary as long as the ninth; and the tail emarginated. However, while the family character of a pectinated or serrated middle claw is considered diagnostic, it has been reported as being absent from some specimens of *Phodilus* and in some specimens of at least one taxon of *Tyto*, namely the southern Andaman race *deroeptstorffi* of the Common Barn-owl.

In 1875, R. B. Sharpe recognized only five species of *Tyto* in the second volume of the British Museum Catalogue of Birds. This was quite extraordinary in an era when a large number of species were often recognized. A year later, however, in 1876, Sharpe explained this treatment by publishing his notes on his revision to highlight the considerable variation known for, in particular, the Common Barn-owl. He also included *Phodilus* with Tytonidae.

In the most recent full revision of *Tyto*, by E. Hartert in 1929, Sharpe's treatment was considered to be neither consistent nor logical. Hartert's review of the Common Barn-owl has been the basis for subsequent treatments, with only a few subspecies no longer recognized. His review of the Eastern Grass-owl (*Tyto longimembris*) was tentative and was clarified in later reviews by D. Amadon, who additionally combined this form with the African Grass-owl (*Tyto capensis*) in a single species.

Fourteen species of *Tyto* and two of *Phodilus* are currently recognized. Within *Tyto* the number of species has often been quoted as around eight to ten, but more species are now generally accepted. *Tyto* is represented by four groups: sooty-owls (two species); masked-owls (six); typical barn-owls (four); and grass-

With its very wide, virtually cosmopolitan distribution, it is hardly surprising that the Common Barn-owl has evolved a large number of subspecies. Some of these may merit full specific treatment.

The Galapagos subspecies, although distinctive enough, has not yet been elevated to that status. On the other hand, the Ashy-faced Owl, until relatively recently considered conspecific with the Common Barn-owl, is now generally afforded full species status.

Right: *Tyto glaucops*, Santo Domingo Zoo, Dominican Republic. Photo: Josep del Hoyo/Lynx]

owls (two). The greatest diversity of species is found in Australia, New Guinea and islands west to Sulawesi, including all the sooty-owls and masked-owls. The typical barn-owls and grass-owls overlap in parts of southern Asia west to India and in Africa south of the Sahara. Elsewhere, only the typical barn-owls occur.

It is thought that the masked-owl group along with the sooty-owls may be relicts of an ancient radiation which subsequently contracted, leaving behind isolated representatives in Wallacea, Melanesia and Australia. Later, though still in ancient times, the typical barn-owls and the grass-owls would have resulted from another more far-reaching radiation, with separate centres of speciation, for example in the West Indies.

The sooty-owls number two species. In the early 1980's it was proposed that the Lesser Sooty-owl (*Tyto multipunctata*) of north-east Australia should be separated from the Greater Sooty-owl (*Tyto tenebricosa*) of south-east Australia and New Guinea, on the basis mainly of differences in size, plumage and voice. While this creates an unusual distribution pattern, it is shared by at least one other bird genus, that of the logrunners, *Orthonyx*. There has been much recent work on Australian populations of these owls, but New Guinean birds remain poorly known. While most authors now accept the split into two species, some consider the New Guinea populations to be equally distinctive, which could imply their promotion as a further species, although others might use this instead to call for the regrouping of all forms into a single species once again.

The masked-owl group is currently considered to comprise six species, including several isolated and poorly known island endemics. The Australian Masked-owl occurs widely in Australia and also in southern New Guinea. North-east of New Guinea are found the Golden Masked-owl (*Tyto aurantia*) on New Britain and the Manus Masked-owl in the Admiralty Islands. West of New Guinea are the Lesser Masked-owl (*Tyto sororcula*) of the Tanimbar Islands, Buru and Seram; the Taliabu Masked-owl (*Tyto nigrobrunnea*) of the Sula Islands; and the Minahassa Masked-owl (*Tyto inexpectata*) of northern Sulawesi. However, the taxonomic status of many forms within this group is far from clear. All six are currently placed in a single superspecies, and until quite recently many of them were frequently considered races of a single more widespread species. Again, the Taliabu and Minahassa Masked-owls are occasionally considered conspecific; the fact that the former is known only from a single specimen, together with recent field observations, means that it is very

difficult to make meaningful assessments, and indeed there are those who might instead make this form conspecific with the Australian Masked-owl. At the other end of the scale, the large, dark Tasmanian form *castanops* of the Australian Masked-owl is frequently considered a full species in its own right, although recent studies suggest that its differences from the closest mainland populations of nominate *novaeollandiae* are probably best reflected as subspecific. It has also been suggested that the Australian Masked-owl's form *calabyi* from southern New Guinea might be approaching separate species status, although this proposal has received little support. As in the case of the sooty-owls, this New Guinea form is very similar to the southern Australian nominate race, but less so to the geographically much closer north Australian races, though even in this latter zone the differences would appear relatively slight, especially within the context of this very variable species. A further dubious case within this group is that of the form *cayelii* of the Lesser Masked-owl, which occurs on Buru and Seram. This taxon may represent another separate species from the Tanimbar form, *sororcula*, while the Seram population may involve a separate race yet to be described. All in all, there are a great many uncertainties within the masked-owl group. Apart from recent studies of Australian birds, the group is very poorly known and includes some of the least-known owls in the world.

By contrast, the Common Barn-owl has the distinction of being one of the world's most widely distributed landbirds, as well as the most intensively studied of all owls, particularly in Europe and North America. However, of the 28 subspecies presently recognized, most are poorly known, and some isolated populations may represent separate species. This has proved to be the case for the Ashy-faced Owl of Hispaniola, now separated from the Common Barn-owl, and reckoned probably to include the dark barn-owls of the Lesser Antilles, although these might represent a further species, *T. insularis*. Other isolated island forms that might merit promotion to full species include the current races *detorta* of the Cape Verde Islands, *thomensis* of São Tomé, *deroepstorffi* of the southern Andamans, and *punctatissima* of the Galapagos. Interestingly, birds from both the North American race *pratincta* and the Australian race *delicatula* were introduced to Lord Howe Island, off north-eastern Australia, and declined to interbreed; this was taken as evidence that the two taxa should not be considered to belong to the same species. However, further investigation was cut short, as

The two sooty-owls were long regarded as representing a single species. Their present treatment, as separate species forming a superspecies, is based on differences in size and plumage, as well as in voice. A glance at their individual distributions may cause some surprise, however, since the Greater Sooty-owl is found in New Guinea and in south-eastern Australia, while the area between those two regions is occupied by the other species, the Lesser Sooty-owl (*Tyto multipunctata*). The situation is further complicated by the fact that the New Guinea population, although still poorly known, is sometimes thought to be distinctive enough as to represent a third species; other taxonomists may feel that, if New Guinea birds are that different, then this could support the argument for re-merging all sooty-owl populations into a single species comprising several well-marked subspecies. Clearly, there is a need for much more study of this group of attractive birds, particularly at the extremes of the range.

both forms went extinct on the island, leaving possible conclusions in the air. The two other members of the group of typical barn-owls are poorly known but very distinctive island endemics: the dark-backed Sulawesi Owl (*Tyto rosenbergii*) of Sulawesi, Sangehe and Peleng, which has also been allied with the masked-owls; and the Madagascar Red Owl (*Tyto soumagnei*) of eastern Madagascar.

Grass-owls are commonly treated as two species, although they are still often combined as one. Despite the disjunct range that is produced by such a "lump", morphological differences between the two forms are minimal, while subspecific variation within the Eastern Grass-owl is notable, so the case in favour of splitting is by no means overwhelming. The African Grass-owl has been the subject of various studies, particularly in South Africa. The rarity of the Eastern Grass-owl through much of its range has limited the amount of information available on it, but recent work in Australia has begun to fill some of these gaps.

What little is known about the two bay-owls of the genus *Phodilus* tends to support their inclusion in Tytonidae as a distinctive subfamily of isolated, relict populations. The Oriental Bay-owl (*Phodilus badius*) ranges extensively through South-east Asia, but is considered very rare throughout its range. What is known of it in life is limited to random observations over many years on voice, behaviour, nest-sites and eggs, with no other details of breeding. Even this is considerable when compared with our knowledge of the Congo Bay-owl (*Phodilus prigoginei*), a remarkable species discovered in Africa as recently as in 1951. The type specimen, a female, was the sole definite source of information until another female was mist-netted and released at the same locality in 1996, though there were two probable records from the intervening period. In the past, it was strongly argued that the Congo Bay-owl should really be treated merely as a race of the Oriental Bay-owl, as it was said to be virtually identical. Although little new information of note has been unearthed, it is now generally agreed that the differences are a good deal more marked than previously suggested, and indeed the two may not even be congeneric.

Some nomenclatural confusion has concerned tytonid owls in the past owing to problems over the application of the Linnaean

genus *Strix*. Prior to 1910 the *Tyto* owls were placed in *Strix* or its synonyms, such as *Aluco*, until G. M. Mathews called attention to the availability of *Tyto*. Within the typical strigid owls, *Strix* replaced *Syrnium*, with *Strix aluco* as its type. The Common Barn-owl had been most widely known as *Strix flammea* and its family as Strigidae, while all other owls were placed in Bubonidae or Asionidae, so name changes were required. At the species level, too, changes in nomenclature have proved necessary. For example, the Eastern Grass-owl was long known as *Strix candida* until Mathews at the same time demonstrated the unavailability of *candida* and the application of *longimembris*.

Morphological Aspects

Owls of the genus *Tyto* have a large, rounded head with a heart-shaped facial disc, a narrowly tapering body with a short, squared tail, long legs, and strong feet with well-developed talons. In flight, the blunt-headed shape makes them appear top-heavy, with long wings and long, often trailing, legs. The exceptions are forest-adapted forms with rounder wings for flight among trees, and smaller forms with less robust feet and talons. The longer legs are more prominent in forms inhabiting open country.

Tyto owls are characteristically darker on the upperparts, with variable markings, and paler on the underparts, with or without markings. The palest forms, of temperate and arid regions, are light grey with some buff or golden-yellow wash on the upperparts, which are delicately marked in intricate patterns of white, grey and black, while their white underparts are either unmarked or have dark flecks or spots, these often confined to the sides of the breast and belly. The darkest forms are dark brown or black, with the underparts only slightly paler, and are also intricately patterned above and spotted or flecked below. Many variations are found between these extremes. The markings may be apparently random or may form loose vermiculations or barring, but never the heavy streaking shown by many of the Strigidae. Overall, the effect is cryptic and serves to camouflage hunting and roosting birds against predation from above; the paler underparts of many species contrast less with the sky when seen by prey from below, while the darker forms blend with their darker backgrounds, such as forest or lava rock, as in the Galapagos. Some forms occur in light, intermediate and dark colour morphs, and the ratio of light to dark is also a reflection of habitat adaptations generally. Such influences of habitat and hunting behaviour have not only made these owls well adapted to their environments, but, in the case of the Common Barn-owl, have resulted in a diversity of races with similar plumage patterns in different regions of the world. These variations and convergences explain the difficulty faced by R. B. Sharpe in the nineteenth century in defining species limits (see Systematics).

As a rule, females are larger and darker than males, and the degree of difference may be considerable. In many forms the generally paler appearance of the males is considered to be advantageous, as males do most of the hunting during the breeding periods. Females tend to have larger and darker spots on the wings and tail, giving a barred effect, and larger and more numerous dark spots or flecks on the underparts.

Newly fledged young of both sexes are generally darker than their parents until after the first moult, when breeding age is reached. Females become paler with age, and older females may approach paler males in colour. They are heavier than males and their weight fluctuates throughout the breeding period, while males tend to be of a similar weight all year around. The lightest birds are found among races of the Common Barn-owl, with a weight of as little as 187 g recorded, while the heaviest are the dark females of the Tasmanian race of the Australian Masked-owl, which weigh up to 1260 g. The latter are also the largest tytonids, at 57 cm long, whereas some races of the Common Barn-owl and some other taxa are as small as 26 cm, and Oriental Bay-owls can measure only 23 cm. Size differences within species, sometimes combined with plumage differences, have been used to define racial variation, but there can be much individual variation in widespread populations, while small size is more constant in smaller populations, such as those on islands.

Owing to their rarity, the bay-owls are very little known. Of the two species, the Oriental Bay-owl has the wider distribution and has been better studied. Its relationship with the genus *Tyto* is perhaps debatable, but on current evidence its inclusion as a subfamily within the Tytonidae appears to be warranted. By contrast, treatment of the virtually unknown Congo Bay-owl (*Phodilus prigoginei*) as a subspecies of the Oriental, as was formerly argued, is surely untenable: indeed, to judge from its external appearance, the African species seems unlikely even to be congeneric with the Oriental Bay-owl.

Their characteristic pattern and coloration makes barn-owls instantly identifiable, both to the professional and to the layman. The typical plumage, as shown by this Common Barn-owl, is dark above, with a variable amount of golden-buff and with a delicate spotting and flecking of grey, white and black; the underparts are much paler, often whitish, with or without dark spots. Cryptic plumage of this kind is found among many birds, although one may wonder about the effect of such pale underparts for a bird which does much of its hunting in the darkness of night.

Tyto owls are supremely adapted to nocturnal hunting. The facial disc is formed by layers of stiff, dense feathers which act as reflectors amplifying sounds, including high frequencies. The heart shape of the disc forms two concave troughs running along the sides of the face. The asymmetrical positions of the external ears allow the owls to determine the location of sounds. The left ear is higher than the right one and so, when the owl turns its face towards the sound source, the orientation of the disc is slightly downward on the right and upward on the left. By comparing the extremely fine differences in the timing of the sounds in both ears, the owl can determine the direction of the noise of potential prey, as well as distinguish prey sounds from other sounds, such as rustling leaves. The owl can also locate concealed prey, such as in grass or under snow. The optimum foraging height appears to be around 3 m, either when hunting or when preparing to strike. While it has been demonstrated that Common Barn-owls can hunt in what appears to the human eye to be complete darkness, they also hunt visually in variable light conditions at night and early or late in the day, for instance in the tropics; or for more extended periods, such as during the long days of summer at high latitudes. The degree of nocturnal hunting is also indicated by eye size, the sooty-owls, which are also known to hunt in complete darkness, having the largest eyes.

The silent flight of these owls reduces the chance of audible detection by small mammal prey and helps them locate prey sounds when hunting from the air. Three adaptations of the flight-feathers assist in providing this silent flight. First, the leading edges, particularly of the outer primaries, have a prominent, stiff, comb-like fringe, providing a laminar air flow that reduces noise; second, the trailing edges of the primaries and secondaries have a soft, hair-like fringe that helps to reduce turbulence where the air flows across both sides of the wings meet; and last, the primaries, secondaries and wing-coverts have a downy surface that reduces the noise made by their contact during wingbeats. The wings are also broad, giving a high surface-area to body-mass ratio which increases lift and allows slow flight and sudden turns without stalling. The low wing-loading also allows heavy prey to be carried at slow speed, thus reducing the power output required and minimizing energy consumption, which is advantageous when prey is being delivered frequently to the nest. Such flight movements when hunting, combined with long, slender legs and large

toes and claws giving a wide spread at points of contact, make these owls efficient hunters in a variety of habitats.

Bay-owls are like small dark *Tyto* forms, but with the facial disc divided at the forehead and forming ear-like extensions of the ruff margin of the disc, which is less complete above the neck. Their general appearance is that of small forest owls superficially resembling their *Tyto* counterparts, the sooty-owls, and in particular the smaller, tropical Lesser Sooty-owl. All taxa of bay-owl are dark, variably brownish, and more heavily marked on the upperparts, while they are more uniformly coloured and slightly paler on the underparts, a pattern in which they resemble the *Tyto* owls to a fair degree.

Studies of the moult of the Common Barn-owl have demonstrated a complex sequence that differs from that of strigid owls,

The distinctive outline of *Tyto* owls in flight is well demonstrated by this African Grass-owl. The large head makes the bird appear markedly front-heavy, and the relatively long legs protrude noticeably beyond the short, square-ended tail. The legs are particularly long in those species living in open country, as do the two grass-owls. This individual, flushed from its regular daytime roost in rank Imperata grass in an extensive marshy area, is a subadult, aged by the more buffy colour of its underparts.

can be determined after fledging by the sequence of moult of the primaries. The first moult usually replaces the central P6 only, the second moult usually 2-4 primaries either side of P6, and the third moult renews the remainder. Subsequent moults usually see the primaries, still centred on P6, replaced every two years. The secondaries and the tail feathers are also not completely replaced until after the first three moult phases. While tropical birds replace all wing and tail feathers over about seven months, the sequence is similar to the temperate three-moult sequence. Outer primaries are usually replaced rapidly, while the inner primaries and secondaries are renewed over a longer period. The timing of moult is strongly influenced by food supply and extends over the entire breeding period. In years when prey numbers are low the moult phases are slower.

Habitat

Tytonidae is essentially a tropical family that ranges into higher latitudes. Most species are confined to tropical forest and some adjacent habitats from the coast up to and beyond the tree-line, reaching about 4000 m in the Andes and New Guinea.

Both sooty-owls are rainforest specialists. In south-east Australia, the Greater Sooty-owl prefers old-growth forest, often wet gulley forest, dominated by tall eucalypts, with creeks and a dense understorey of smaller trees and ferns. Although also extending into drier forests to hunt, it is sensitive to disturbance and its presence is a good indicator of the biodiversity in a given habitat. In New Guinea, the species ranges to about 4000 m above sea-level and is also found in *Araucaria* pine forest. It sometimes hunts above the tree-line in boulder-strewn alpine grassland and along ridges, as well as in clearings at lower elevations. Within its much smaller range, the Lesser Sooty-owl shows a similar preference for pristine forest, usually occurring in clearings and disturbed areas only for the purposes of foraging.

The tropical masked-owls are all restricted to lowland and mid-montane rainforest, but they may occur at the forest edge and in adjacent lightly disturbed habitats when hunting. The Australian Masked-owl occurs widely in all forest habitats, preferring tall open forest with large trees for nesting and roosting and a diverse understorey with ground cover for hunting. Inland, its

The silent flight of tytonid owls is aided by several special adaptations. One of these is the stiff, comb-like fringe at the leading edges of the flight feathers, especially the outer primaries, visible on this Madagascar Red Owl as it stretches its wing. This produces a laminar flow of air across the wing, helping to reduce noise. The facial disc is composed of layers of stiff, dense feathers which amplify sounds, thereby further facilitating nocturnal hunting. The orange-red plumage gives this very rare species its vernacular name. This individual, perched 27 m up on a large trunk, is one of the sole pair to have been studied to date.

[*Tyto soumagnei*, near Ambanizana, Masoala Peninsula, north-east Madagascar. Photo: Russell Thorstrom]

providing further support for the separation of Tytonidae. However, while birds of temperate regions moult their juvenile set of remiges and rectrices over three moult phases from their second to their fourth years, followed by a two-year moult cycle, those inhabiting tropical regions apparently moult all their wing and tail feathers each year. The age of temperate Common Barn-owls

Sexual dimorphism is not particularly well marked in the Tytonidae. Females are generally larger and darker than males, and often have more spots on the underparts, but in many cases the sexes are distinguishable only by size. The Australian population of the Eastern Grass-owl, however, is a possible exception. Although it seems that some females of this largely terrestrial species are very similar to males, many have a noticeably darker facial disc and underparts. Juveniles either resemble females or are darker still.

[*Tyto longimembris longimembris*, Australia. Photo: Roland Seitre/Bios]

foraging habitats may extend to wooded farmland, tree-lined watercourses, pine plantations and isolated tree stands, and in northern Australia also paperbark (*Melaleuca*) swamps and mangrove edges. More remarkably, in the south of the continent one population has adapted to underground caves of the treeless Nullarbor Plain.

In contrast to the case of forest species, the habitat diversity of temperate populations of the Common Barn-owl is limited only by prey availability, by seasonality and the severity of winters at higher latitudes, and possibly by competition from other predators. This owl prefers lowlands with scattered tree cover, such as non-intensive farmland featuring hedges, ditches, ponds, banks, roadside verges and similar habitat mixes, young pine plantations, and villages, towns and suburbs with tree cover and unoccupied buildings suitable for daytime roosts and nest-sites. Tropical and subtropical races range from rainforest to the xerophytic vegetation communities of arid and semi-arid regions, including shrub and herb communities, mixed woodland, savanna, heath, marshland, mudflats, cliffs and rocky coasts, including some continental offshore islands. These races also occur in urban landscapes, as well as plantations, rice paddies, cane fields and irrigated fields. On smaller tropical islands Common Barn-owls enter all available habitats, although some races depend on areas of undisturbed rainforest for breeding.

While the tropical relatives of the Common Barn-owl, the Ashy-faced and Sulawesi Owls, are sometimes found in forest, they are more characteristic of open woodland, forest edge and cultivation, and also occur around villages and towns. Recent observations show that even the rare Madagascar Red Owl, hitherto known only as a resident of undisturbed rainforest, may be beginning to adapt to secondary-growth woodland with clearings.

Grass-owls occur widely in the Old World tropics and reach South Africa in the west and southern Australia in the east. The African Grass-owl, perhaps because of competition from the strigid Marsh Owl (*Asio capensis*) in particular, is generally restricted to undisturbed grassland at elevations of up to about 3200 m, marshes, *Acacia* woodland and floodplains, including vleis in South Africa. The Eastern Grass-owl is sparsely distributed through Asia to Australia in similar grassland, floodplains, savanna and marsh habitats up to about 2500 m. In Australia, it appears to break up into eastern coastal and inland populations,

never having established permanent breeding populations farther south than subtropical areas. It prefers undisturbed areas but is also found in cultivation, such as cane fields and young pine plantations, and in cleared areas. Inland grass-owl populations, as with many inland birds affected by the wet and dry seasonality of available habitat and food resources, are highly nomadic and can be locally common where several good wet seasons have resulted in high rodent populations. In subsequent drier conditions these inland birds disperse widely, with most apparently moving north to tropical savannas, marshes and swamps, and it has been suggested that the northern coastal populations may not be permanent but a consequence of deteriorating conditions for inland birds.

The bay-owls are both forest specialists, and the sooty-owls may be their ecological counterparts in Australia and New Guinea. The Oriental Bay-owl is found in lowland and mid-montane rainforest and mixed deciduous forest, but it also occurs at the edges of mangroves, and in plantations and old clearings, utilizing the clearings probably only when hunting. The little information available on the Congo Bay-owl indicates that it is a forest owl that also hunts in disturbed forest, clearings and probably plantations.

General Habits

Tytonid owls are, with few exceptions, strictly nocturnal. They occur solitarily or in pairs, and are generally sedentary birds occupying a territory throughout the year, which may or may not be defended outside the breeding period. Territory size varies with breeding and non-breeding activities and, particularly in temperate regions, with prey availability, quality of foraging habitat and prevailing weather conditions. The distribution and density of territories can at times be limited only by the availability of suitable nesting sites and roosts. Studies of the Common Barn-owl in Europe and North America show much variation in territory requirements, but where conditions for breeding are good the optimal number of pairs will establish and maintain territories. A similar maximum exploitation of suitable habitat has also been demonstrated for sooty-owls, grass-owls and the Australian Masked-owl. Sooty-owls and masked-owls are more strongly territorial than are typical barn-owls and grass-owls.

While most tytonids are forest-dwelling species that sometimes extend into adjacent habitats, the most widespread member of the family can be encountered in an extraordinary variety of habitats across its worldwide range. Tropical races of the Common Barn-owl can be found in rainforest and in xeric habitats, as well as in various types of woodland and grassland, in coastal regions and in semi-urban and even urban areas. Populations in temperate parts of the range prefer lowland areas with some tree cover, often farmland with hedges, banks and ditches, and with unoccupied buildings in which to roost and nest. Barns and outbuildings are frequently used.

[*Tyto alba alba*,
Ávila, Spain.

Photo: Francisco Márquez]

In contrast to the Common Barn-owl (*Tyto alba*), the two sooty-owls are habitat specialists, more or less confined to the rainforest of Australia and New Guinea. Their requirement for undisturbed and undegraded forest has meant that they are only infrequently recorded, and disturbance of the habitat leads to a decline in their numbers. The rarer of the two, the Lesser Sooty-owl, lives mostly at altitudes above 300 m and is seldom encountered outside the forest proper; it appears in clearings and in areas adjacent to the forest only to hunt.

[*Tyto multipunctata*, Paluma, Mt Spec-Crystal Creek National Park, north Queensland, Australia.
Photo: Clifford & Dawn Frith]

A high density of breeding pairs with overlapping territories in a few regions suggests loose colonies, and pairs may defend an area of only about 5-10 m around the nest. Territories are established by males and are sometimes occupied over several years. If one member of a pair dies, the other may continue to defend the territory or may re-establish itself in a new one, usually no more than a few kilometres away. A female has been recorded defending the same territory for nine years, but the mortality rate of adults means that most individual territories last only about two years. One of the effects of maintaining territories is that, if prey is scarce, some birds will starve rather than move to a more favourable area; another is that pairs may at times be found breeding close to the nest-sites of other owl species and raptors.

Resting owls hang their plumage loose and stand on one leg with the body leaning forwards, the facial disc flattened and the eyes closed. The plumage is often preened at this time in order to maintain peak feather condition for hunting. Other maintenance activities observed for the Common Barn-owl include bathing in a stream in sunny weather, as well as sunning by lying on a well-lit patch of ground and raising one wing to expose the side of the body to the sun. These activities may also help to control ectoparasites. If the owl is disturbed when roosting, it draws its body upright and holds its wings tight and partially wrapped around the body; for those species and subspecies which have pale underparts, this posture helps to conceal that conspicuous part of the plumage.

Common Barn-owls are sensitive to disturbance, and their threat displays are very similar to those that have been observed in other *Tyto* species. If threatened by an intruder, the owl bows towards the source of the threat and spreads its wings, tilting them forwards with the tail raised and spread; the head is lowered to show the nape and is swung from side to side, this action accompanied by hissing and bill-snapping. If cornered, the owl sways its lowered head and upper body from side to side while standing alternately on one foot then the other, ruffles its plumage, lowers its wings, and spreads its tail. The head is shaken and moved up and down while the bird glares at the source of danger, hissing with the bill open and making sudden forward lunges. If attacked or approached too closely, the owl may raise a foot,

lean backwards and strike forwards with its talons. The spraying of faeces at the source of threat has also been recorded. If the owl is then picked up, it may feign death, closing its eyes and lying prostrate. These displays vary, depending on the circumstances, and are not used against others of its own kind. Fledged young are bolder than adults and sometimes use such displays to mob mammalian predators.

The general habits of the bay-owls are almost unknown. The two species are strictly nocturnal and easily disorientated if found in daylight. A threat display of the Oriental Bay-owl observed in Malaysia exhibits similarities with that of *Tyto*. The owl stood up on stretched legs, turned towards the observers, inclined its body forwards, and arched its wings out and down to below the level of its toes. In this posture it swayed from side to side, then suddenly bowed its head deeply and shook it while facing nearly backwards between its own feet. For a few seconds it exposed its neck and nape, then the head was flung up and forwards to expose the pale facial disc with its large staring eyes and open bill. This sequence was repeated before the bird flew away. While some aspects of the threat display are found in some strigid owls, the bowing and shaking of the head is certainly characteristic of the Tytonidae.

Voice

The voices of tytonid owls are characterized by various screeches, screams and shrieks, in addition to some chirruping and whistling sounds. A cacophony of cackles, chatters, chuckles, croaks, hisses, purrs, rasps, snores, squeaks, trills, twitters, wails, wheezes, yelps and even yodels is usually associated with breeding activities and variously uttered by males, females and their young in the nest and later near it.

In 1980 a German study by P. Bühler and W. Eppe summarized the calls of the Common Barn-owl, placing them in five groups. These are variations of the sounds listed above, in their different forms and combinations representing courtship, contact calls, pair-bonding, begging and feeding calls, and defensive and territorial behaviour. In 1982, the vocal repertoire of this species in England was categorized by D. S. Bunn and colleagues

In the arid, harsh interior of Australia, the Common Barn-owl is forced to retreat from the heat of the day by taking refuge in a suitably cool cavity. This species is, in fact, largely nocturnal, although, in many parts of its vast range, it is not uncommonly seen hunting at or just before dusk and around dawn; on occasion it even appears in the middle of the afternoon, especially if disturbed from its daytime roost. Common Barn-owls are often associated in people's minds with old, disused buildings, barns and similar artificial structures, but one of the most frequently used sites for roosting and nesting is a large natural cavity in a tree trunk. Such sites are adopted in all parts of this adaptable species' range, the main condition for its presence being not, as sometimes believed, the availability of old barns and the like, but an adequate supply of prey and, partly implicit in that, a winter climate that is not too severe. Competition from other predators can also be a factor in its occurrence or otherwise in apparently suitable areas.

Auscape]

into at least 12 types of sound. In addition, this species is known to make mechanical sounds in the form of both Bill-snapping and Wing-clapping.

We also have some idea of the range of calls of the three other *Tyto* groups. They all have distinctive features in both vocal character and calling behaviour, but the types of call known so far suggest similarities with the Common Barn-owl. For example, grass-owls make cricket-like chirruping calls in flight, and sooty-owls give a characteristic piercing, descending whistle, likened to the sound of a bomb falling, while the Australian Masked-owl screams louder than other *Tyto* species within its range.

The voice of the Oriental Bay-owl is characterized by various screams and whistles, even a soft hoot. A well-known description of its scream was that it sounded like half a dozen cats fighting. The whistling calls include short, three-noted and longer, more musical sequences. One of the "probable" records of the Congo Bay-owl was of a bird uttering a structurally similar call.

Food and Feeding

As with so many other aspects, our knowledge of the diet of tytonid owls rests heavily with that of the Common Barn-owl, which has been studied in greater detail than any other owl. For seven other species we have a good idea of their diet, for three we know very little, and for five species we know nothing.

In general, tytonid owls are predators of small to medium-sized mammals, with birds, reptiles, frogs, insects and other prey of incidental, seasonal or local significance. The typical barn-owls and grass-owls are specialized hunters of small mammals, especially rodents and shrews (Soricidae), with voles (Cricetidae) of particular importance to temperate Common Barn-owl populations. Sooty- and masked-owls in Australia and New Guinea take a range of marsupials as a major part of their mammal diet. The Oriental Bay-owl appears also to be a hunter mainly of small mammals, although birds and other prey may be important, but nothing is known of the relative percentages of different prey and all available data remain anecdotal, as is the case, too, with the little-known *Tyto* species.

Pellet analysis has been the principal source of dietary data for the Common Barn-owl and other *Tyto* species so far studied. The Common Barn-owl's stomach is known to have a pH higher (less acidic) than that of most other predatory birds, with the result that even small, delicate bones may be found intact in its pellets. Not only does this ease identification of prey species, but also studies have found that the proportions of prey identified in pellets match other sources of data, such as food remains at nest-sites and photographic evidence of prey delivered to nests. However, a study in Mali found that, for some pairs that fed almost entirely on frogs and toads, the remains of such prey did not show in pellet analyses, which underestimated the importance of amphibians in the diet. A recent Israeli study of Common Barn-owl pellets aimed at determining the ecology and distribution of mammal prey suggests that the pellets do not represent the actual proportions of the available prey species in their real communities, but they do give an accurate indication of the owls' preferences, though showing a bias towards larger prey species, with most items identified falling in a weight range of 51-100 g.

The most recent major analysis of Common Barn-owl diets was that undertaken by I. R. Taylor in 1994. He combined the results of his 14-year Scottish study with 51 previously published reports selected on the basis of the length of study and the number of birds involved, also including shorter-term studies to give a broader geographical coverage. The representation is Europe (22), Middle East (1), Africa (7), North America (15), South America (2), South-east Asia (1) and Australia (4), which is also a good indication of the global ratio of all studies of Common Barn-owl populations.

Taylor found that the proportion (in terms of numbers) of small mammals in these 52 samples was 74-100%, making up over 90% in 42 cases. As a general rule, small mammals are most important in moist, temperate regions, the great majority being terrestrial species weighing 3-100 g, although in most studies

Wing-stretching is a commonly indulged-in habit among many birds of all families, and the Tytonidae is no exception. This behaviour helps to keep the plumage in good working order, and also ensures that the individual feathers are correctly aligned when the wing is folded again. Barn-owls, when perched, generally hold their plumage rather loose; if suddenly disturbed or alarmed in any way, however, they immediately draw the body upright and press the wings tightly against the sides. In such situations, the Common Barn-owl, and almost certainly its relatives as well, also wraps its wings partly around the front of the body, a posture which goes some way towards concealing the conspicuous pale underparts that would otherwise easily attract the attention of a potential enemy.

[*Tyto alba alba*, near Ringwood, Hampshire, England. Photo: Mike Read/Planet Earth]

One of the frequently practised maintenance activities recorded for barn-owls is demonstrated by this individual. Perched on a favourite post, with body leaning slightly forwards and plumage hanging loose, the owl stands on one leg and scratches its face with the other. This is part of the general preening routine that keeps the feathers in peak condition for hunting and helps to maintain general health.

The majority of birds are creatures of habit. This Common Barn-owl is one of a breeding pair which regularly used this particular post; every evening, the bird perched on it and preened for a short while before flying off to hunt. In this posture, and in such a close-range view, the golden-buff crown with its wonderfully delicate pattern of dark dots superimposed on a light grey veil-like bloom is revealed to advantage.

Any intrusion near the nest of a barn-owl is likely to elicit the distinctive defensive or threat posture that so characterizes the Tytonidae. The spread-wing posture is typical, having the effect of making the bird appear bigger than it actually is. The bird first bows in the direction of the intruder and spreads its wings wide, at the same time turning them forwards so that their upper surface faces the source of the threat, and raises and spreads its tail; it lowers its head and swings it from side to side, while uttering hissing sounds and snapping with the bill.

prey usually fell within a narrower weight range, often below 50-60 g. The weight of prey and the number of animals taken at higher latitudes are also influenced by the Common Barn-owl's need to maintain a higher body temperature than other high-latitude owls and by its sensitivity to cold weather. While various bat species are widely taken, bats never contribute significantly to the overall diet. In 47 of the 52 studies, rodents comprised at least half of all prey items, and in 33 cases over three-quarters. In individual studies, the number of prey species that were recorded as making up at least 0.5% of the total prey items ranged from two to 25. Most diets, however, were dominated by a few species, and of those species recorded with residual representation, together comprising the last 10-20% of many diets, none accounted for more than a small percentage of the diet.

In Europe and North America, the variety of mammalian prey generally declines with increasing latitude, but with some exceptions: for instance, in central Europe up to 18 species were taken, compared with 5-11 in Britain and Ireland and 10-15 in the Mediterranean region. In general, the more productive an area is, the fewer prey species are consumed. For example, where voles are available, a single species can make up 40-90% of the diet. In Australia, all sample studies showed that a single rodent species accounted for over half of the diet, but three of the four studies were carried out when the rodents were in plague numbers so the possible importance of other species needs further study. In Africa, rodents of up to 25 species usually form 80-90% of prey items, but 5-6 species may make up 80% of prey, compared with 3-4 in Europe and 2-3 in North America. In all except arid regions, shrews are the most important non-rodent species.

Where small mammals are scarce or absent and other prey is abundant, Common Barn-owls have adapted locally to alternative diets. In the Namib Desert in southern Africa lizards may comprise about half of the owl's food and scorpions are also important, while a study at the Karnak Temple, in Egypt, found doves (Columbidae) and sparrows (Passeridae) forming nearly half of the diet. In Mali, some pairs depend almost entirely on frogs and toads; and in coastal Guinea-Bissau the diet is dominated by birds, including weavers (Ploceidae), sunbirds (Nectariniidae), kingfishers (Alcedinidae), waders (Charadriiformes) and swifts (Apodidae). On some of the Cape Verde Islands reptiles, particularly geckos (Gekkonidae), are often taken, along

with a variety of birds including plovers (Charadriidae), godwits (*Limosa*), Ruddy Turnstones (*Arenaria interpres*), Collared Pratincoles (*Glareola pratincola*) and weavers. Also in island groups and on some continental offshore islands where seabirds breed, pairs of Common Barn-owls may move in and raise their young entirely on a diet of petrels and shearwaters (Procellariidae), terns (Sternidae) and other seabirds. This is the case, for example, on offshore islands of California (USA), on Razo in the Cape Verde, and for introduced populations in Hawaii and the Seychelles. Some owls also take advantage of communally roosting passerines such as starlings (Sturnidae), thrushes (Turdidae), weavers and Red-winged Blackbirds (*Agelaius phoeniceus*). Such specialized bird-eaters are probably opportunists, like those Common Barn-owls that take advantage of such phenomena as mass hatchings of winged termites.

Both grass-owls are rodent specialists. In Africa, rodents can represent 76-98% of the diet, ranging in weight from 1.5 g to 120 g. African Grass-owls take larger prey, on average, than do co-occurring Common Barn-owls and Marsh Owls. As well as consuming rodents, grass-owls in Africa feed on shrews, elephant-shrews (Macroscelididae), hedgehogs (Erinaceidae), hares (Leporidae) and bats, while Eastern Grass-owls in Australia take dasyurid marsupials (*Sminthopsis*, *Planigale*); both species have also been recorded preying on ground birds, reptiles, frogs and large insects. Inland Australian birds join other owls to take advantage of cyclical rodent plagues. However, several studies have shown that, when prey numbers crash, many grass-owls are unable to find other food and consequently starve.

Greater Sooty-owls are mainly specialists on arboreal mammals such as possums, pygmy-possums and gliders (Burramyidae, Petauridae), but also take terrestrial mammals, including potoroos (*Potorous*), dasyurid marsupials (*Antechinus*, *Sminthopsis*), small wallabies (Macropodidae), forest bats, rabbits and rodents, covering a weight range of 18-900 g. Birds and large insects have also been recorded as prey. In New Guinea, it is likely that large wallabies are consumed as carrion. The Lesser Sooty-owl is more dependent on terrestrial prey, as is the Australian Masked-owl, though its diet is otherwise similar to that of the sooty-owls.

The Oriental Bay-owl is known to eat small mammals. There is little information on the species concerned, but there is an old record of one found dead with the wing bone of a bat protruding

If an intruder, human or otherwise, does not retreat in response to the threat display of a barn-owl, the latter continues with more aggressive behaviour.

It lowers its head and the whole of its upper body and sways them from side to side, while shifting from one foot to the other, with plumage ruffled up to increase its apparent size even more; the wings are lowered somewhat, and the tail spread. Following this, the irate bird shakes its head and moves it up and down, staring straight at the source of danger, all the time uttering loud hissing sounds and from time to time suddenly lunging at the intruder.

If this does not have the desired effect, or if the intruder comes closer, the owl may even make a direct attack by leaning backwards and striking with its sharp talons; occasionally, it may squirt faeces at the enemy. Recently fledged young commonly give such threat displays, and instinctively direct them against mammalian predators, not always unsuccessfully. Tytonid owls do not normally, however, use them against conspecifics. It is interesting to note also that a barn-owl, if picked up by a human being, will not usually put up a struggle; rather, it is likely to lie on its back, with eyes shut, and pretend to be dead. A further point of interest is that, although some owls of the family Strigidae demonstrate certain similarities in threat displays, only the tytonid owls are known to perform the bowing and head-shaking behaviour.

Compared with "typical" barn-owls and grass-owls, the masked-owls and sooty-owls appear to exhibit stronger territoriality. Studies of the Australian Masked-owl, which usually inhabits tall open forest with big trees, have revealed that it exploits all suitable habitat within its range, with the optimal number of pairs maintaining territories; these are estimated to be c. 1000-2000 ha in size. This maximum use of available habitat is paralleled by the Common Barn-owl (*Tyto alba*) in the northern hemisphere, where field research has revealed similar results.

[*Tyto novaehollandiae*, east Australia.

from its stomach. Birds, lizards, snakes, frogs and large insects have also been recorded, but it is not known whether mammals form the majority of this owl's diet, nor whether there are regional variations, although among avian prey a preference for flowerpeckers (*Dicaeum*) has been noted in parts of Borneo. Nothing whatsoever is known of the diet of the Congo Bay-owl.

Common Barn-owls hunt in two different ways: by dropping down onto prey from a perch, and by a searching flight low over the ground with occasional hovering and undulations. Their soft, sound-damping plumage, their asymmetrical ears and their heart-shaped facial disc collecting and channelling sound waves, combined with their long legs, demonstrate superb adaptations for nocturnal hunting (see Morphological Aspects). Experiments have shown that Common Barn-owls can hunt efficiently in what is, to a human being, total darkness. Upon locating prey by either sight or sound, they dive in its direction from a height of about 3 m, with talons extended. The long, broad wings provide a low wing-loading that enables slow aerial searching and the carrying of a heavy prey load. Depending on habitat type and diversity, perch-hunting can also be common. In high latitudes such as in northern Europe and North America, Common Barn-owls sometimes hunt in daylight, especially in mid-summer, when there may be little choice, or when rain has restricted nocturnal hunting. Daylight hunting has also been observed in the tropics and may occur widely, provided that it does not lead to mobbing by smaller birds. Common Barn-owls usually hunt alone in a territory, although where prey is particularly abundant, as in Australia during rodent plagues, large numbers may gather in a small area with other owls, including grass- and masked-owls.

Grass-owls hunt by low, quartering flights, gliding and hovering rather like harriers (*Circus*), and usually start earlier and finish later than do the typical barn-owls. Australian Masked-owls, like Common Barn-owls, combine low hunting flights and perch-hunting.

Greater Sooty-owls normally hunt inside closed forest, in the canopy, on tree trunks and on the forest floor. In Australia, they are less inclined to hunt from low perches if there are breaks in the ground cover; in New Guinea, birds inhabiting montane forest also hunt over alpine and subalpine grassland, particularly where there are rocks and other potential cover for prey. Greater Sooty-owls have also been observed to hunt in pairs, with the

male in the canopy and the female close behind but nearer to the forest floor. The Lesser Sooty-owl is also an efficient forest hunter but it makes greater use of low perches, often perching on the sides of tree trunks, and using tracks and clearings. Both sooty-owls are known to hunt at times in total darkness, and the Lesser also forages during heavy rainfall. Although sensitive to habitat disturbance, Greater Sooty-owls sometimes hunt in logged and open areas, even at roadsides, and they take a higher proportion of terrestrial prey, but only where their hunting territory also includes undisturbed forest.

Bay-owls, like sooty-owls, hunt in the forest canopy, and their shorter, more rounded wings are well adapted for rapid flight among the maze of trunks and branches. They also hunt from perches, using the sides of tree trunks, where they rhythmically rock the head, presumably to focus on the location of the prey

Most owl species, when located at their daytime roost or if active before other birds have retired to their nocturnal roost, attract furious mobbing from other birds. Even avian species which do not figure in the owl's diet react in this way, as shown here by these two Black-backed Magpies (*Gymnorhina tibicen*). Perhaps the latter, which feed on smaller birds and mice, regard the owl as a food competitor; but that can be only part of the explanation.

[*Tyto alba delicatula*, Kakadu National Park, Northern Territory, Australia.
Photo: Roland Seitre/Bios]

The members of the Tytonidae are essentially nocturnal. Even though individuals of some species, such as the Common Barn-owl, can sometimes be seen during other hours of the day, the vast majority of the family are unlikely to be visible to the human observer until darkness arrives. Only then does the owl emerge from its roost, as a ghostly aerial figure floating off to its hunting grounds. Tytonids spend the day out of sight in a dark cavity, either in a tree or in dense foliage, or in a suitable niche in a building.

before rapidly catching it in flight. Again, like sooty-owls, they are strictly nocturnal and it is probable that they regularly hunt in total darkness.

Breeding

The first breeding studies on the Common Barn-owl date back over a century, with observations at the nest going back even farther, to Gilbert White's accurate and highly detailed remarks, in his classic work on natural history first published in 1789, on the behaviour of a pair breeding in his own church at Selborne, in Hampshire, England. In more recent times, several books and hundreds of papers have been devoted to this species, making it the best-known owl in the world. Much of this work is based on the European and North American races, but this is complemented by contributions from Africa, South-east Asia, Australia and South America. However, while details on most of the 28 races of the Common Barn-owl are incomplete, anecdotal or non-existent, a comprehensive picture has emerged that appears generally to characterize the whole genus *Tyto*. For the other *Tyto* species, recent studies have provided a general picture of the grass-owls, the Australian Masked-owl and both sooty-owls, but too little is currently known of the rest of the genus to allow any meaningful discussion of their breeding behaviour. The bay-owls remain poorly known in general, with very limited information available for the Eastern and nothing at all known about the African.

Within the family, then, there is a vast abyss between the state of our knowledge concerning the best-known and least-known species, and for many of our generalizations about the family as a whole we must rely on extrapolating, with caution, from the extensive research carried out on the well-known species. While nothing at all is known of the breeding of six of the species, and next to nothing about two more, the Common Barn-owl continues to be the object of much research, from which very interesting conclusions are emerging. For example, this species featured as the subject of three books in 1994 alone, all based on studies in Britain. One of these, by I. R. Taylor, discusses the results of a 14-year study by the author in Scotland and presents a comparative review of Common Barn-owl studies elsewhere

(see Food and Feeding). In North America, the current research of C. Marti is notable. His 1997 report on the lifetime reproductive success of a Common Barn-owl population in Utah, near the northern limit of its breeding range, is based on data collected from 1977 to 1995. Marti has demonstrated that the owl has a reproductive strategy which is quite unlike that of most other raptors and more like that of a small passerine: a short but highly productive breeding season.

These "passerine" breeding habits associated with the Common Barn-owl may apply to grass-owls too, particularly the inland Australian population. However, from what is known of masked-owls and sooty-owls, their breeding rates are low and are probably influenced by territorial behaviour and habitat availability. Australian Masked-owls are strongly territorial and pair-members may stay together all year, often using the same nest-site over many years. Pairs can be found breeding 1-10 km apart, and in south-east Australia territory size has been estimated at about 1000-1200 ha. Similarly, Greater Sooty-owls appear to mate for life and are also strongly territorial, with territory sizes estimated at about 200-800 ha. They produce a single meagre clutch per season, and may not nest at all in unfavourable years. The spatial distribution of territories in undisturbed habitats suggests that the populations of sooty- and masked-owls have long existed at optimum levels, and that, where there is disturbance, numbers decline because the recruitment rate of young birds is too low. Nevertheless, it has been found that in captivity, with a plentiful food supply, the Greater Sooty-owl will breed when one year old and will raise two broods in a year, each with up to three young, which is about triple the normal breeding rate in the wild.

With their cosmopolitan distribution, Common Barn-owls are always breeding somewhere in the world. Although breeding can start in any month in the tropics, there is some seasonality, with egg-laying usually starting late in the dry season, or in the wetter periods in more arid regions. As latitude increases, distinct non-breeding periods emerge. In northern temperate regions, the source of most data, laying begins with increasing temperatures in spring and coincides locally with the initial breeding activity of mammalian prey species; but the numerous young of such prey species may not be available for another 2-3 months, by which time the owl nests will have half-grown chicks, so warmer weather and the resulting increased activity of small mammals are vital to

Broadly speaking, the principal food of tytonid owls is small to medium-sized mammals. A recent analysis of the diet of the Common Barn-owl, by far the best-studied species, found that small mammals constituted 74-100% of this species' prey in terms of numbers. The analysis examined the results of 52 studies of pellet contents carried out in all parts of the range, thus indicating a very widespread dietary preference. Interpretation of such results requires some caution, however, since not all prey types show up in pellet analyses. Nevertheless, it seems reasonably certain that small mammals are, indeed, the primary food of this species. In rural habitats, the Common Barn-owl is able to exploit a readily available source of rodents: this individual is about to seize a mouse (*Apodemus*) attracted to a sack of grain in an old outbuilding.

[*Tyto alba alba*,
Rackheath,
Norfolk, England.

Planet Earth]

the actual initiation of a breeding attempt. As a consequence, first laying dates vary widely, depending on annual weather patterns and prey population cycles: ranges of 47 days have been recorded over 12 years in Scotland, and 53 days over eight years in France, but only 15 days over five years in New Jersey, USA. Other influences include habitat variation and the age of females, with older females laying earlier on average. By starting early, a pair may be able to rear two broods, with an average-sized brood taking nearly four months to produce.

The breeding period is usually March-June in northern forms of this species, but if two clutches are involved, the respective periods are usually March-May and June-August. The number of second clutches laid shows much regional variation, and can be linked to the available habitat diversity and the population cycles of small mammals. The laying of three clutches, although rare, has been recorded in a German study and may be more frequent in the tropics, for example in Malaysia. In an extreme case, four clutches were produced within 11 months by a breeding pair in Zimbabwe during a mouse plague. Where the owls depend on more stable and homogeneous agricultural landscapes, the breeding seasons are similar each year. In Australia Common Barn-owl breeding is more opportunistic, with large-scale movements and irregular nesting influenced by temporary increases in local populations of small mammals, but breeding peaks are recorded in March-June and August-November.

Most of the other species for which details are known would seem, like the Common Barn-owl, to have some populations breeding somewhere more or less at all times of the year, mainly due to local variations. This is the case of the African Grass-owl, which breeds when grass cover is at its peak, and thus can be found breeding somewhere within its tropical African range during most of the year; in South Africa, the period is October to July, centred around the austral summer. A similar pattern of local variations emerges for the Eastern Grass-owl, which breeds mainly from October to March in Asia, in May and June in New Guinea, between February and September in coastal Australia, and whenever conditions are favourable in inland Australia. The other three relatively well-known species, those occurring in Australia, can likewise be found breeding at almost any time of year, though they show moderate variations in their peaks: most Australian Masked-owls lay from March to July, northern birds starting earlier; Greater Sooty-owls usually lay between January and September, with a peak around April; while in the Lesser Sooty-owl most egg records are in March-May, the season depending essentially on rainfall. The few records available for the Oriental Bay-owl show breeding from March to May in India, a record of nestlings in November in Sri Lanka, and laying from October to December in Borneo.

Two main kinds of nest-site prevail throughout the family, those situated on the ground amidst grass and those in natural

cavities, typically in trees. The African Grass-owl's nest consists of a flattened pad of grass at the end of a tunnel in a dense grass tuft, often near or under a bush. The nest is part of a network of tunnels which the owls make by pushing through the grass, and these can serve as escape tunnels if the nest is threatened at some stage. The closely related Eastern Grass-owl has similar grass nests with tunnels, though it shows some apparent differences in potential nest-sites, sometimes nesting near mangroves and in young pine plantations.

The sooty-owls, masked-owls and typical barn-owls, as well as the Oriental Bay-owl, are cavity nesters. The Greater Sooty-owl nests mainly in tree cavities, using large tree hollows at heights of some 10-50 m, but it will also breed in rock crevices and caves, preferring large caves with nest-holes high above the floor. There is no nest as such, and the eggs are laid in the debris of the nest-site. The Lesser Sooty-owl likewise nests in tree cavities, and indeed appears to be very similar to the Greater in all aspects of its breeding biology. Australian Masked-owls nest in tree cavities, using large hollows in both trunks and branches, at heights of about 12-25 m, preferring tall trees isolated by location or by their height above surrounding trees. At the chosen site, a depression may be made in the nest debris. Interestingly, in the Nullarbor Plain of southern Australia, in the absence of tree sites, a small population of Australian Masked-owls has adapted to nesting on cliff ledges and in cave clefts. Sadly, though, this population is declining and indeed it may already have disappeared, so the ability of the species to adapt to such sites in the long term remains poorly known. Nothing is known of the other masked-owls, but a Minahassa Masked-owl was recently seen at a probable nest in a tree hole too, and it seems likely that all members of this closely related group will have similar habits. The Oriental Bay-owl's nest is an unlined hollow in a tree trunk or rotten stump, no more than 2-5 m above the ground. One nest-site of this species was recorded as having been used over many years, becoming heavily littered with pellets and other debris. However, a more remarkable case is known for the Greater Sooty-owl, in which birds are often extremely site-faithful; it was calculated that one cave site, according to the layers of prey remains on the floor, had been occupied by countless generations of these owls for about 10,000 years!

A natural cavity-nester, the Common Barn-owl has also become dependent on man-made structures in many parts of its wide range. So long as it has enough room, adequate entrances and exits and little or no disturbance, just about any such structure will be used. Familiar examples include churches, towers, barns, castles, abandoned cottages and warehouses, but nests have also been found in such places as chimneys, wells, duckblinds (hides), unused boats and cavities around bridges. Natural sites are holes in tree trunks, stumps or large, hollow branches, 2-20 m above ground, the tops and hollows of palm trees, cracks and fissures in cliffs, burrows in banks, rock crevices, caves and lava tubes, and even on the ground. Common Barn-owls readily take to nestboxes, usually provided as part of local conservation plans, but also used in some areas to effect rat-control programmes, such as in oil palm plantations in Malaysia. Preference for natural sites varies regionally, and is more widespread in the USA than in Europe. While all populations of this species are sensitive to the presence of human activity, North American birds appear to be more so than their European counterparts, although this may be partly a consequence of the presence of more mammalian nest-predators such as raccoons (*Procyon*).

Nest construction in the Common Barn-owl involves making a slight scrape or depression, where possible, and the female using pellets and other debris to form a pad for the eggs, with an insulating layer of mammal hair from the pellets. In the south-western USA, the owls wholly or partially excavate a nest-burrow up to about 1 m deep in a bank or cliff. Some pairs make use of large abandoned nests, such as those of Ospreys (*Pandion haliaetus*), or take over, or more rarely share, active nest-sites of other birds, such as Eurasian Jackdaws (*Corvus monedula*). In this owl species, too, sites may be occupied for several seasons.

In the Common Barn-owl, breeding activity usually begins 6-8 weeks before laying, but there is much individual variation, particularly in the behaviour of males. Some roost with the female at the nest-site during winter, although most roost apart. Males start spending more time at potential nest-sites at night and call more frequently, presumably to advertise ownership of the site and to attract a mate. They also use a ritualized advertising display flight, call in flight, and make short aerial excursions over the area around the nest-site with stiffened, deliberate

Once caught, prey is carried back to the nest, or to a favoured feeding spot, in the bill. This is one of the ways in which the feeding and foraging habits of both families of the order Strigiformes differ from those of the diurnal birds of prey (Falconiformes), which normally carry food in their talons. Direct observation and photographic evidence help to confirm the results of pellet analysis in determining the diet of owls: it is quite remarkable how frequently tytonids are shown to be carrying or about to swallow rodents.

[*Tyto alba alba*,
near Reims,
north-east France.

wingbeats. The time the male spends in and around the nest peaks in the two weeks before laying and during laying, but when the clutch is complete most males return to their usual roost-site. This form of mate-guarding also involves frequent copulation, starting before hunting begins and being repeated many times during the night. Much of the courtship behaviour of the Australian Masked-owl is apparently similar, males calling from nest-sites for potential mates; in display flight the male circles around high above the tree tops, calling the whole time.

An important part of courtship behaviour in the Common Barn-owl is food presentation, not only to maintain the pair-bond, but also to facilitate the necessary weight increase of the female for egg production, which can influence the size and timing of the clutch. The female stays at the nest for 10 days prior to laying, when the male provides all the food, often in excess of her requirements. Unmated males may accumulate large stockpiles of prey in their efforts to attract a mate. In this pre-laying period sexual chases occur, in which the male and female fly in and around the nest-site at high speed. Inside the cavity, they indulge in a great deal of bill-fencing, mutual preening, tongue-clicking, squeaking, twittering and hissing. In a few cases where a male attracts more than one female to the nest, he may mate with the second female; the latter then produces a clutch at a nearby nest-site, but is usually less productive. Taylor found seven such cases in 14 years of study.

The eggs tend to be a rounded ovoid, though those of the Eastern Grass-owl are more pearl-shaped. It is highly typical of both *Tyto* and *Phodilus* that the eggs are white when laid but soon become discoloured by nest debris. In rare instances, at least in the Common Barn-owl, newly laid eggs may be marked with brown flecks. Average weights of fresh Common Barn-owl eggs are 17.9 g for the subspecies *alba*, 17.5 g for *guttata* and 26.6 g for *pratincola*, the first two representing 4.9% of the female's weight and the third 4.8%. The small egg size in relation to the female is characteristic of cavity-nesting birds, but in this species it seems also to be an adaptation to large clutch size, and an aid to raising large broods.

Clutch size is rather variable across the family, with sooty-owls and masked-owls laying much smaller clutches than those of the typical barn-owls and grass-owls, and bay-owls perhaps in an intermediate position. The data collected to date show: 1-2

eggs, usually two, in the Greater Sooty-owl; 2-4 eggs, usually just two, in the Australian Masked-owl; 3-5 eggs in the Oriental Bay-owl; 2-6 eggs, normally four, in the African Grass-owl; 3-8 eggs in the Eastern Grass-owl; and 2-14 eggs, most commonly 4-7, in the Common Barn-owl. It is noteworthy that in the Common Barn-owl, with its large clutch, most of the hatched chicks survive, whereas from the Greater Sooty-owl's typical clutch of two normally just a single chick survives. The laying interval ranges from two days for the Eastern Grass-owl, to at least 2-3 days for the Common Barn-owl, and about four days for the Greater Sooty-owl.

Intraspecific variation in clutch size is, of course, best known in the Common Barn-owl. In Scotland, Taylor found that earlier clutches were larger, but the opposite was the case in studies he compared from Germany, France and Mali. The variations appear to be influenced by changes in vegetation cover, prey numbers and prey activity, and, in Scotland, by the better survival of young fledged from earlier clutches, regardless of clutch size. However, in years of peak prey abundance, 15% or fewer of the Scottish pairs laid a second clutch, whereas those in central Europe and Mali had a higher incidence of second clutches. In years of low food supply some pairs do not breed, but the extent to which this occurs is unknown.

In the Common Barn-owl, and probably in other species, the female effectively undertakes all the incubation, and she develops a brood patch for this purpose, a feature absent in the males, which rarely sit on eggs and then only for brief periods. In the Common Barn-owl, incubation lasts 29-34 days, usually 30-32 days, which is about 10% longer than for other cavity-nesting owls. However, the period is even longer in most other hole-nesting tytonids, taking 35-42 days in the Australian Masked-owl and about 40-42 days in the Lesser Sooty-owl. It can be equally lengthy in the ground-nesting grass-owls, taking 32-42 days in the African, though about 31 days in the Eastern.

A few days before hatching, young Common Barn-owls can be heard calling from within the egg. Most of them hatch overnight, using the egg-tooth, and the female sometimes assists by removing pieces of shell and fragments of membrane. Broken shells and unhatched eggs are typically left in the nest. The hatching success rate in this species is related to egg quality and food supply but does not seem to vary greatly. Examples of 83% in

One of the two ways in which Common Barn-owls hunt is by slow searching flight low over the ground, occasionally hovering briefly, or from time to time rising or falling a little. This slow quartering is made possible by the long, broad wings, which provide low wing-loading. Such foraging usually takes place over areas of long grass or similar rank vegetation, or along edges of ditches or dykes. On locating prey, either by sight or by sound, the owl dives on to it. Although this species not uncommonly forages in the half-light just before or just after night, it is able to hunt with equal success in total darkness.

[*Tyto alba alba*, Norfolk, England. Photo: Richard Brooks/Aquila]

Mali, 82% in France, 71% in Germany and 69% in Malaysia were quoted by Taylor, who recorded rates of 85% in plantations and 76% in farmland. The majority of eggs that failed to hatch were found to be the last or penultimate eggs in their clutches, and the few complete hatching failures involved females which were underweight as a result of food shortages.

When hatched, European Common Barn-owl chicks weigh about 13-14 g. Hatching is asynchronous, at intervals usually of 2-3 days, producing a size hierarchy. African Grass-owl chicks hatch within 1-2 days of each other, and the evidence suggests that size differences are probably, correspondingly, slightly less marked. At a Sri Lankan nest of the Oriental Bay-owl, the three nestlings found were of different sizes, indicating that *Phodilus* also exhibits the asynchronous hatching characteristic of *Tyto* species.

In the Common Barn-owl, the first down, the neoptile, is sparse and the chicks need to be brooded by the female until the second, mesoptile, down starts to grow after 12 days, this becoming fully developed by about day 20. They are not left alone in the nest until the youngest is 12-16 days old, and they huddle together to minimize heat loss. The growth rate of chicks peaks at 16-19 days, with an increase of 12-14 g per day recorded in Europe and 22 g per day in the USA. Weight gains vary, depending on whether the broods hatched earlier or later in the breeding season. Young Common Barn-owls reach their maximum weight by 36-40 days, when they weigh more than their parents; depending on food supply and the number of young in the brood, they may stay above the adult weight when they leave the nest. Skeletal growth is also completed by about day 40. Growth of primary feathers starts around day 10, but these are not fully developed until the young are 70-75 days old.

Prey-delivery rates to 19 Common Barn-owl nests studied in Scotland were obtained by using automatic recording equipment. Rates increased from around 8-10 times per 24 hours during incubation, when the female was fed on the nest, to a peak of 14-16 times when the chicks were about 30 days old, an average of 4.2 items per chick per day; they declined thereafter, but with some prey still being delivered when the youngest chick was about 85 days old. The estimated daily food intake per chick during the peak consumption period at 30-40 days was 98-108 g.

Such details are essentially lacking for the other members of the family. However, it is worth noting that the total fledging

period shows considerable variation, ranging from about 42 days in the African Grass-owl, and some 60 days in the Eastern Grass-owl and the Greater Sooty-owl, to about 70-84 days in the Australian Masked-owl, and 90 days in the Lesser Sooty-owl; the period is unknown for both bay-owl species. In many species the fledged young are known to take some time before becoming wholly independent, and while both grass-owl species and the Australian Masked-owl will stay near their nests for several weeks, the young Greater Sooty-owl remains with its parents for up to six months.

Variations in the mortality rates of Common Barn-owl chicks are linked to food supply and usually affect the younger members of the brood. For example, in Scotland, when prey numbers were low, the mortality rate was 26% for first-hatched young and 94% for the last. The overall mortality rate between hatching and fledging was 5-10% in years of high prey abundance and about 45% in low years. In high-abundance years, 70% of deaths were of chicks under 10 days old, and very few died after day 20. In poor years, most died before day 20 but numbers of deaths up to fledging were substantial. Dead chicks in nests are usually fed to their siblings.

Regionally, annually and within breeding seasons, there is much variation in the fledging success of Common Barn-owls. All variations can be attributed to food supply, but habitat differences may also be influential. Long-term studies have shown total production of young per pair per year to range from 1.6 in the Galapagos Islands to 7.0 in Malaysia, with a range of 3.1-5.3 in Europe and 1.9-4.0 in the USA. A German study examined annual changes in the number of fledged young per pair over seven years and three cycles of peak prey numbers; the results were 2.4-4.3 for first broods only, and 2.4-7.1 for first and second broods combined, where second broods were produced in five of the seven years by 17.1-55.6% of females.

In his study of the lifetime reproductive success of a Common Barn-owl population in Utah, USA, from 1977 to 1995, C. Marti found that it varied widely among individuals, with a few birds producing a disproportionate number of the next generation. Compared with other raptors, including four other species of owl, on which similar studies have been undertaken, the Common Barn-owl has moved in the direction of trading ■ long life for rapid and intensive reproduction. The early maturation, large

Prey items, when not carried back to the nest or deposited nearby for later consumption, are normally taken to a perch to be eaten. If not too large, prey are swallowed whole; bigger items are pulled apart before being eaten piecemeal. In certain circumstances, such as during rodent plagues, larger numbers of owls of several species, along with other predators, may assemble in one area to take advantage of the easy pickings. In most cases, however, tytonids hunt solitarily within their own foraging territory.

clutch size, multiple clutches and low survival rate are characteristic of species adapted to harsh environments. Common Barn-owls must reproduce quickly and intensively to maximize their fitness. Marti studied 357 nesting attempts by a minimum of 473 birds and documented the history of 262 individuals. On average, the age of first breeding was 1.06 years, the number of years of breeding was 1.30, and the number of years of breeding successfully was 1.03. In one year, 11% of the pairs produced two broods. The average number of eggs produced in a lifetime was 9.76, and of young fledged 5.58. Of the females that laid eggs, 8% laid a quarter of the population's eggs, 55% laid three-quarters and 22% produced no fledglings at all; 12% left breeding descendants, with up to four generations traced, the number of direct descendants ranging from three to 69. The age when females started breeding had no strong effect on lifetime success, and breeding age had a negligible effect on clutch size and the number of fledglings produced in a single season. Other potential influences on lifetime reproductive success examined in this study were habitat variability, age and sex of individuals, and variability of winter severity. The first of these three factors was found to have no influence, while age and sex had very little; harsh winters, however, had a strong negative influence on adult survival and clutch size, but none in terms of numbers of fledglings produced in the next breeding season.

Movements

All tytonid owls are essentially sedentary, even at higher latitudes, although some post-breeding dispersal does occur, especially among first-year birds. Breeding pairs normally stay within their territories, but, depending on food supply during non-breeding periods, they sometimes wander into the territories of other pairs; the extent of such movements may also be influenced by territory size and adult mortality rates. Fidelity to both nest-site and mate, which were found to be over 90% for Common Barn-owls in Scotland over two consecutive years, also support the idea of generally sedentary breeders, but it is not yet clear how far these results can be applied elsewhere. For example, a high

fidelity rate seems to be shared by Common Barn-owls in France and west-central USA (Utah), but not by those in Germany and eastern USA (New Jersey).

Known dispersal of tropical forms includes records from offshore islands and other areas outside the habitats normally frequented, such as would result from altitudinal movements. Such observations are few, however, and the evidence suggests that the normal pattern is for adults to stay in or close to their breeding territories, with most records from elsewhere attributable to post-breeding dispersal of first-year birds. The extent of dispersal in the tropics and subtropics is unclear but it is probably not great, although the recovery at Bo, in southern Sierra Leone, of a Common Barn-owl 1000 km from where it had been ringed at St Louis, northern Senegal, is notable, as also is an observation of an African Grass-owl from Ethiopia, some 900 km outside its normal known range. An exception to the general pattern appears to be in Australia, where some populations of Common Barn-owls and Eastern Grass-owls, particularly those occurring inland, are highly nomadic. These owls undertake irruptive movements associated with rodent plagues, as well as seasonal dispersal north and east in winter, and some movement away from coastal areas in summer. Ringing recoveries of Common Barn-owls involving distances of 65-840 km have been reported from south-east Australia, with vagrants reaching as far as New Zealand.

Inland Australian grass-owls generally disperse to northern coastal regions, where they also breed. Evidence suggests that northern coastal-breeding birds are not resident all year round. This temporary northward dispersal may also account for grass-owl records farther north, from some Indonesian islands and southern New Guinea. North of the equator, too, there is some evidence of dispersal, with possible vagrants in Hong Kong, involving the race *chinensis*, and one record from the southern Ryukyu Islands, the latter a bird of the Taiwanese race *pithecopus* or possibly the Philippine race *amauronota*. Vagrants have occurred in New Caledonia, Fiji and south-west Australia, but dispersal to south-east Australia may include temporary breeding activities. The wide but scattered occurrence of the Australian Masked-owl in parts of central and southern Australia is also a consequence of nomadic behaviour in some regions. All records of long-distance movements of sooty-owls, however, probably involve first-year birds only.

Most information on dispersal patterns comes, inevitably, from studies of post-fledging dispersal of European and North American Common Barn-owls, based on direct observations, ringing recoveries and radio-tagging. There is much regional variation, but in general most British birds disperse to within 20 km, European birds to within 50-100 km, and North American birds to beyond 80 km in the north and within 80 km in the south. Both continents have recorded long-distance recoveries, up to 1600 km in Europe and 1760 km in North America. Young ringed in the Netherlands, for example, have been recovered about 1500 km away in Spain and Ukraine. The evidence suggests that such movements are not entirely the result of severe winter weather. While birds may disperse in all directions, most move southwards. Barriers to dispersal include mountains and large water bodies, yet there are vagrancy records that obviously required over-water flights, one example being the recovery in Bermuda of a bird ringed about 1250 km away in New Jersey. However, Common Barn-owls have been found on ships up to 360 km from land and on offshore oil rigs; such assistance may account for some of the long-distance records, a circumstance not confined to owls. The most unusual evidence of assisted long-distance vagrancy comes from several of the New Zealand records of Common Barn-owls which were of birds travelling in the undercarriage bays of large aircraft. One of these apparently arrived from North America and, not surprisingly, was found dead on arrival, but Australian birds have survived the rigours of the flight and some of the survivors are even suspected to have been "stowaways" from Fiji.

From ringing recoveries in Britain, it has been found that within the first 1-2 weeks after fledging 37% of Common Barn-owls had dispersed over 3 km from the nest, the figure increasing to 59% by 5-6 weeks. Radio-tagging of eight individuals in Wales revealed that movement away from their respective nests varied, with two

Although rodents and other small mammals form the basic diet of the Common Barn-owl, its food spectrum ranges from larger mammals, birds, reptiles and amphibians to fish, insects, spiders and scorpions, and earthworms. A surprisingly wide variety of birds has been recorded as prey of this owl. Passerines, such as this Blackbird (*Turdus merula*) are among the most frequently taken, but in some parts of its range this owl actually specializes on seabirds, such as shearwaters and petrels (*Procellariidae*) and terns (*Sternidae*); in other areas, waders (*Scolopacidae*) and plovers (*Charadriidae*) can make up a significant proportion of its diet.

The sooty-owls of Australia and New Guinea hunt mostly in closed forest, where they feed on both arboreal and terrestrial mammals, supplemented by far smaller numbers of birds and insects. Common prey animals include dasyurid marsupials, and pygmy-possums and gliders (Burramyidae, Petauridae). Both species are known to be capable of hunting with great efficiency in total darkness, and this is reflected in the size of their eyes, which are larger than those of any other tytonid.

The Lesser Sooty-owl will also hunt during heavy rainfall. The latter species catches some of its prey in the forest canopy, but, compared with the Greater Sooty-owl (*Tyto tenebricosa*), it tends to make far more use of the middle and lower forest strata, often using low perches and the sides of tree trunks, and sometimes exploiting the opportunities offered by clearings and forest tracks.

As a consequence, it catches a greater percentage of terrestrial prey than does its somewhat larger relative, a fairly large proportion of its diet consisting of ground-dwelling rodents.

The Lesser Sooty-owl depicted here would appear, from its rather heavily patterned underparts, to be a subadult. Having caught a rodent, it proceeds to swallow it whole in the manner typical of the family.

A high frequency of copulation is characteristic of the Common Barn-owl. The peak in this activity generally occurs in the two weeks prior to egg-laying and continues during the laying period; at this time in the breeding cycle, matings can be repeated almost without a break during the night. The rate of copulation decreases during the incubation and chick-rearing periods, but does not cease altogether. The pair shown here had young four weeks of age, yet continued to mate. Such behaviour serves to reinforce what is already a very strong pair-bond.

birds leaving at each of 2-3, 3-4, 4-5 and 6-8 weeks after fledging. This variation may relate to such factors as the extent of parental post-fledging feeding, availability of prey, competition from other owls, and the learning of hunting skills. In Germany, 27% of ring-ing recoveries within a month of fledging were at over 10 km and 18% were between 50 km and 100 km; in the second month, 27% were found less than 10 km away and nearly 40% more than 50 km away, with dispersal stabilizing 4-5 months after fledging.

Studies of overall movements indicate that in Britain 53% of birds bred within 10 km of their natal site and 90% within 50 km; in Denmark 86% bred within 50 km; in Germany fewer than 40% nested within 50 km and 30% at over 100 km; and in France and the Netherlands 70% bred within 50 km. More evidence is required, but it appears that most females disperse farther than most males; in Scotland, for example, males usually settle within 5 km of their natal site, but females usually at 6-10

Among tytonids, and indeed all members of the Strigiformes, the task of incubating the eggs is undertaken by the female. The male's responsibility is to supply food to his mate. On rather infrequent occasions, however, the male will cover the eggs for a short period if the female leaves the nest; unlike the female, however, he does not possess a brood patch, and would consequently be far less efficient were he to attempt incubation proper. Such egg-covering by the male is always brief, and he immediately stops when the female returns.

[*Tyto alba alba*, near Ringwood, Hampshire, England. Photo: Mike Read/Planet Earth]

Favoured nest-sites are often used repeatedly over a considerable period of time. This tree hollow, situated in a dense rainforest, had apparently been used by Lesser Sooty-owls for many years in succession. The floor of the cavity is littered with numerous skulls of mammals, and some bird skulls. The female is about to consume a pygmy-possum (Burramyidae), a common prey of this species.

km. This dispersal pattern may help avoid inbreeding, but the relatively small distances involved still indicate a high proportion of closely related individuals in local populations. The wider movements of mainland continental birds suggest a more successful strategy for maintaining genetic diversity. While inbreeding is a potential problem in all island or otherwise isolated populations, it would be of interest to compare the situation in Britain with that of Common Barn-owl populations living on much smaller islands.

In North America, northern and southern (up to 3° N) populations of Common Barn-owls show marked differences in post-fledging dispersal. In 1952, P. A. Stewart reported that 56.8% of ringing recoveries of northern birds were within 80 km of their natal sites, with 31% more than 160 km away, but for southern birds 88% were within 80 km and none was found more than 160 km away. Basing his conclusion on mostly southern recoveries of northern birds over six months old, 43.7% of which were found over 160 km and 27.7% over 320 km from their natal site, and on other evidence, Stewart considered northern birds to be partly migratory. This has been discussed by later authors based on observations at Cape May, in New Jersey, where large numbers of owls have been recorded in autumn. In his recent book on Common Barn-owls, I. Taylor attributed such movements to post-fledging dispersal, in no specific direction, where large numbers indicated a good breeding season in nearby areas of good habitat. As in Europe, such movements, including long-distance vagrancy, may be the consequence of periods of low prey abundance.

In tropical island groups, such as Fiji, inter-island movements of Common Barn-owls are frequent. In Indonesia, there has been a westward movement of this species over the past 30 years from Java north through Sumatra and smaller islands to the Malay Peninsula. This form of range expansion demonstrates the species' well-known adaptability to habitats and nesting sites associated with human activity, and is similar to its northward expansion in temperate regions over longer periods. Elsewhere, island vagrants may stay on and breed, sometimes permanently, as on Bermuda since 1931, and possibly in the Falkland Islands, where breeding was first recorded in 1989. Historically, such events may well have formed the basis of the radiations hypothesized to have occurred in this family (see Systematics).

Relationship with Man

Since ancient times, and across all cultures, owls have fascinated people. Few other birds have accumulated such a wealth of varying and contradictory beliefs about them. Owls may be either feared or venerated, despised or admired, considered lucky or unlucky, and wise or foolish. They are associated with a wide range of superstitions concerning magic and witchcraft, prophecy, weather, birth, death and many other natural and unnatural phenomena. Owls may turn up in potions, medicines and even recipes.

With its widespread occurrence, nocturnal habits, nesting associations with humans, ghostly appearance and shrieking voice, the Common Barn-owl is probably the source of many recurring owl themes in myths and folklore. It is the White or Ghost Owl, the Demon Owl, the Screaming, Screech or Scritch Owl, even the Hissing Owl; in German it is the *Schleiereule*, the Phantom (or Mystery, or Veiled) Owl; and in French *Chouette effraie*, the Owl of Evil Omen. Another name is the Monkey-faced Owl, suggesting something uncannily "human" about the owl's face, helping it to an association with witchcraft not only as a witch's "familiar", but possibly even as a witch in another form. While it is more likely to be associated with death and the worst of owl superstitions, in some areas the Common Barn-owl can be a symbol of good fortune and luck. As to wisdom, this is usually the province of other owls, for example the Tawny Owl (*Strix aluco*) in Europe.

Common Barn-owls are known to have been present in Britain for at least 10,000 years, and their bones were found among the remains of an Iron Age village at Glastonbury. In Ancient Egypt, identifiable Common Barn-owls are known from wall paintings and bas-reliefs, though varying in details of feather work and head decoration over the dynastic periods. This owl is also among at least six species identified from mummified remains in tombs. Some Egyptians believed that a person had three souls, with the third, named *Ba*, represented as a human-headed bird never flying far from a person's burial site. This belief is thought to have derived from the fact that owls were seen frequenting tombs and temple sites. Today, Common Barn-owls may still be found around such ancient sites. The owl symbol, used in hieroglyphic script as the bird itself or the "m" sound, is variably represented and can resemble the Common Barn-owl as depicted in other forms.

Common Barn-owls use a wide range of nest-sites throughout their range. Man-made structures, including barns, are widely exploited, while natural sites are commonly hollows in tree trunks or large branches. The young are reared on a small scrape lined with pellets and other debris, with mammal hair from the pellets also providing some additional insulation. Chicks are brooded by the female continuously for about two weeks, after which both parents leave to hunt. At this latter stage the young, now in their more protective second (mesoptile) down, huddle together for warmth while the adults are away; since hatching is asynchronous, at intervals of 2-3 days, there is a noticeable size difference among the chicks. By c. 16 days of age, the owlets are able to dismember food themselves, or swallow it whole; they grow rapidly, their weight increasing by up to 22 g daily during the peak growth period at around 16-19 days. In the first week or two of their life, however, they are comparatively helpless and are totally dependent on the female for warmth and food; during this period, the female receives prey from her mate and feeds it to the small chicks bill to bill.

In pre-Columbian America, the owl motif is widespread. While often highly stylized in carvings, totems, masks, fetishes, pottery and other objects, some of these motifs suggest the influence of the Common Barn-owl in particular. For example, a jar from the Mochica people of northern Peru (about 300 BC to AD 800) features an owl with a face mask like that of this species and clutching a rodent in its bill, perhaps indicating an early recognition of this owl's beneficial association. Mayan hieroglyphics, too, include owl symbols, probably representing deities such as

Ah Puch, the god of death, also linked with the god of war and human sacrifice.

This association with death is found among the Zapotec of southern Mexico, who believe that the Common Barn-owl is commissioned to give notice when a man is about to die, and then to go and fetch the soul. In other indigenous New World cultures, owls symbolize courage and strength and sometimes play a symbolic role in warfare, or represent wisdom or animal trickery. These are also recurring themes in other cultures, thus

It is hardly surprising that the Common Barn-owl, with its cosmopolitan distribution, exhibits a very broad range of ecological breeding adaptations. In the USA, the species seems to have a greater preference for natural sites than it does in Europe, and in desertic regions of the former continent it often nests in holes in cliffs or even in the ground.

The dark subspecies inhabiting the Galapagos Islands makes frequent use of cave sites: the individual shown opposite had chosen a small cave in the side of a dry creek bed in the humid highlands, at an elevation of c. 500-600 m.

It is interesting to note that, in the Galapagos, this species fed primarily on the introduced black rats (*Rattus rattus*), following the extinction of the endemic rice-rat.

Common Barn-owl clutches can contain up to 14 eggs, although 4-7 is more usual. Most of those chicks which hatch survive to fledging, although there is a great deal of variation.

Long-term studies have shown the total production of young per pair and per year in the Galapagos to be only 1-6, whereas in Malaysia it is as high as 7-0.

demonstrating a universal theme in how the appearance and behaviour of owls may be interpreted. For example, among some Aboriginal peoples of Australia, a kinship between each woman and the lives of her mother, sisters and daughters was connected to the lives of certain owls and other nightbirds, such as frogmouths (*Podargus*); all "birds of evil omen" were protected by the women, however, since it was unclear which owl guarded which particular soul. Totemic carvings featuring the Common Barn-owl are known from New Ireland, off north-east New

Guinea, where the owl symbol is associated with honouring ancestors; this is of wider interest, as no barn-owl species is definitely recorded from New Ireland.

In the Bible, owls, along with other predators, were considered unclean and were also associated with destruction and ruin. The association with ruins may well have involved the Common Barn-owl, one of at least eight species identified from biblical texts. This species, frequently referred to as the "Screech Owl", or equivalents, throughout literature, appears in Pliny's *Historia*

Grass-owls, as their name implies, are closely associated with grassland habitats. Unlike other members of the family, they nest only on the ground. The typical nest of the African Grass-owl consists of a flattened pad of grass at the end of a grassy tunnel. The owls push their way through the vegetation to create a network of such tunnels, which the adults and young later use as escape routes should the nest be threatened.

The Eastern Grass-owl (*Tyto longimembris*) has similar nesting habits, although it sometimes selects sites below mangroves or in young pine plantations, whereas its African counterpart almost invariably nests near a bush.

[*Tyto capensis*, Transvaal, South Africa. Photo: John Carlyon/Aquila]

Naturalis as a bird of ill omen and an associate of witches, but with some positive aspects. For example, the feet of a Screech Owl burnt together with the herb plumbago is claimed to be effective against snakes. Pliny also advised that, if one lays the heart of a Screech Owl on the left side of a woman as she lies asleep, she will disclose all the secrets of her heart. In his *Booke of Secretes* (1525), Albertus Magnus offered a different version: "For if the heart and right foot of it be put upon a man sleeping he shall say anon to thee whatsoever thou shalt ask of him."

The influence of Pliny endured for many centuries. By the Middle Ages, owls were firmly established in European minds as fearful creatures associated with evil, death, witchcraft, mischief and the unknown. The owl could also be a guardian against the darkness, a theme represented by Michelangelo in his sculpture *Night*, depicting a Common Barn-owl standing alert at the feet of a naked, sleeping woman. When William Shakespeare needed to emphasize the fears and superstitions of his characters, owls were prominently featured, and such symbolism was well understood by his audience of that time. The Common Barn-owl, again as the Screech Owl, provides a good illustration of this:

"The owl shriek'd at thy birth, an evil sign;
The night-crow cried, aboding luckless time;
Dogs howl'd, and hideous tempest shook down trees!
The raven rook'd her on the chimney's top,
And chattering pies in dismal discord sung."
(*Henry VI, Part III*, V, 6);

"Now the wasted brands do glow,
Whilst the screech owl, screeching loud,
Puts the wretch that lies in woe
In remembrance of a shroud.
Now is the time of night
That the graves, all gaping wide,
Every one lets forth his sprite,

In the church-way paths to glide."
(*A Midsummer Night's Dream*, V, 2);

"It was the owl that shriek'd, the fatal bellman,
Which gives the stern'st good-night...
I heard the owl scream and the crickets cry."
(*Macbeth*, II, 2);

and when the witches of Macbeth add a "howlet's wing" to their boiling cauldron, the Screech Owl would seem to be the best source. Compare Ben Jonson in his *Masque of Queenes*:

"The screech owl's egg and the feathers black,
The blood of the frog and the bone in his back,
I have been getting, and made of his skin
A purset, to keep Sir Cranion in."

As well as being prescribed as potions, parts of owls or their eggs were a feature of various folk remedies. For better eyesight, charred and powdered owls' eggs could work, or one could just eat the eyes, depending on where one lived. The use of owl eggs to relieve drunkenness or to bring about a dislike of wine dates back to classical times. This remedy was updated in 1635 by John Swan, in his *Speculum Mundi*: "The egges of an owl broken and put into the cup of a drunkard, or one disirous to follow drinking, will so work on him that he will suddenly lothe his good liquor and be displeased with drinking."

One French variation was to make an omelette of five, nine or 13 owls' eggs. Salted owl could also work. In Poland, rheumatism could be cured by burning owl feathers over charcoal, or eating baked owl. As with the cure for drunkenness, all such folk remedies seem to have ancient roots. Pliny offered a few in the first century, one of which, said to cure haemorrhage, involved the Common Barn-owl: "The bird known as the screech owl is boiled in oil, ewe milk butter and honey being added to the preparation when properly dissolved."

Apart from any purported medicinal properties, owls have appeared on the menu in various parts of the world, with examples dating back at least to ancient Babylon. While owls continue to be offered as a delicacy in some countries, such as China, this is likely to be connected to the survival of folk remedies requiring owls as part of regional traditions of herbal medicine.

The age-old art of storytelling in the form of fables dates back to ancient Indian and Greek texts, notably of Aesop, and features owls as wise or foolish depending on the moral of the tale. These stories, in prose or verse, like many myths and superstitions concerning owls, do not usually enable identification to species, but some certainly suggest the Common Barn-owl as their inspiration:

An Owl of grave deport and mien,
Who (like the Turk) was seldom seen,
Within a barn had chose his station,
As fit for prey and contemplation.
Upon a beam aloft he sits,
And nods, and seems to think, by fits.
(So have I seen a man of news,
Or Post-boy or Gazette peruse,
Smoke, nod, and talk with voice profound,
And fix the fate of Europe round.)
Sheaves piled on sheaves, hid all the floor:
At dawn of morn to view his store
The Farmer came. The hooting guest,
His self-importance, thus exprest:
"Reason in man is mere pretence:
How weak, how shallow, is his sense!
To treat with scorn the Bird of Night,
Declares his folly or his spite.
Then, too, how partial is his praise!
The lark's, the linnet's chirping lays,
To his ill-judging ears are fine,
And nightingales are all divine:
But the more knowing feather'd race
See wisdom stamp'd upon my face.
Whene'er to visit light I deign,
What flocks of fowl compose my train!
Like slaves they crowd my flight behind,
And own me of superior kind."
The Farmer laugh'd, and thus replied:
"Thou dull important lump of pride!
Dar'st thou with that harsh grating tongue
Depreciate birds of warbling song?
Indulge thy spleen: know, men and fowl
Regard thee, as thou art, an Owl.
Besides, proud Blockhead! Be not vain
Of what thou call'st thy slaves and train:
Few follow Wisdom or her rules;
Fools in derision follow fools."
(*The Owl and The Farmer* from John Gay's *Fables*, 1727)

Since the eighteenth century in particular, the association of Common Barn-owls with farms, as well as their known preference for eating rodents, has made them welcome visitors to farms and gardens in many regions, with some farmers even encouraging them to nest by adapting barns and other buildings. The many superstitions associated with these owls have also played a part in such arrangements, as for example in Brittany, in north-west France, where the sighting of an owl in a field was a sure sign of a good harvest to come. In parts of England, it was thought that a scarcity of owls to control rodents could be resolved by hanging a dead owl on or above the barn door. This same custom was followed elsewhere in England, as well as in Germany and France, as a means of averting bad weather, and in Italy to ward off "the evil eye". Even today, in some regions, owls are still shot, trapped or beaten to death to allay various fears or superstitions.

The reputation of the Common Barn-owl as a rat-catcher has led to several attempts to introduce it on small islands as a means of biological control. Regrettably, all such attempts have failed to control rats and, moreover, have had an adverse effect on indigenous bird populations. Introduced in the Seychelles from

Kenya in 1951 and 1952, the owls became a serious threat to the endemic avifauna and local breeding seabirds such as the White Tern (*Gygis alba*), and a bounty was placed on their heads in the 1960's. Common Barn-owls from California which were introduced in Hawaii in 1958-1963 also affected bird populations, including seabirds on their offshore breeding islets. Following the arrival of rats on Lord Howe Island in 1918, attempts to introduce Common Barn-owls from Australia in 1923 and from California in 1927 were unsuccessful, later records being attributed to vagrancy. Australian Masked-owls, however, introduced on the island from 1922 to 1930, did manage to establish themselves, although they, too, have had an adverse impact on local bird populations, including breeding seabirds. The endangered and endemic Lord Howe Rail (*Gallirallus sylvestris*), known colloquially as the Woodhen, was also affected and, as part of the Woodhen Management Plan, the shooting of these owls was considered the most effective control, with 35 shot in 1988-1990. The owl can, indeed, be a bad omen for the local birdlife.

Centuries of folklore and superstition will take a long time to die out or change. Some may even be reinforced in spite of alternative and more logical explanations. For example, in Britain Common Barn-owls are known occasionally to "glow" in the dark, enhancing the image of the ghostly night hunter. A recent explanation is that, when an owl roosts in a hollow tree where luminous bacteria and fungi occur, particles of these organisms may sometimes adhere to its feathering. Some individuals glow quite brightly, as demonstrated by the observations reported in the *Transactions of the Norfolk and Norwich Naturalists' Society* in 1907:

"There are two birds, almost certainly owls, in this district [North Norfolk] which exhibit a hitherto unrecorded phenomenon. I am inclined to believe that most of the tales respecting "will-of-the-wisps", "corpse-candles", and "lantern-men" are the result of occasional luminosity assumed by birds of nocturnal habits that frequently fly over marshy ground in search of prey. For instance, on February 3, 1907, on reaching the top of Twyford Hill, we noticed a light apparently moving in the direction of Wood Norton, and about a quarter of a mile to the north of us. After moving horizontally backwards and forwards several hundred yards, it rose in the air to the height of forty feet or more; then descended and again went through the same evolutions many times. The light was slightly reddish in the centre, and resembled a carriage lamp for which we at first mistook it. We watched it

The characteristic flat pad of grass is clearly visible at this African Grass-owl nest, sited in wet grassland. These owls breed when grass cover is at its peak, making the nest much more difficult to locate. When the chicks are hatching, the female may sometimes assist them by removing pieces of shell. The fledging period for tytonids varies considerably. Although details are lacking for many species, it seems to be shortest in the grass-owls, as would be expected for ground-nesting birds.

[*Tyto capensis*, Grassland Research Station, near Marondera, Zimbabwe.

All owls regularly regurgitate pellets. This ejection of a soft "ball" containing undigested remains of food begins at a very early age, and the nest and surrounding area, including the ground below, can sometimes be remarkably littered with such discarded pellets. Analysis of pellets has proved to be the primary source of information on the diet of owls. Not only is the Common Barn-owl the best-studied species in this respect, but its stomach juices are also known to be less acidic than those of most other predatory birds. As a consequence, even very small and delicate bones are preserved intact in its pellets, enabling a wide range of prey species to be identified.

[*Tyto alba alba*,
Ávila, Spain.

for twenty minutes and were quite at a loss to ascertain its cause. The light emerged from a covert about two hundred yards distant, flying backwards and forwards across the field, at times approaching within fifty yards of where I was standing. It then alighted on the ground for a few seconds. A slight mist hung over the ground. On another occasion, the evening being dark, the bird issued from a covert. Its luminosity seemed to have increased, and it literally lighted up the branches of the trees as it flew past them, occasionally mounting over their tops. After watching it for about half an hour, it was joined by a companion bird hardly so bright. This kept about one hundred yards behind it, but not constantly."

In Western popular culture some aspects of folklore have been borrowed, particularly the owl as a symbol of wisdom. The owl can also symbolize vigilance, a role it has inherited from the iconography of heraldry, which was often stylized from Common Barn-owls. As symbols of evil omen or just as creatures of the night, owls are popular in visual media such as film. In these various guises owls continue to fascinate man and are a popular collectable today, in everything from fridge magnets to works of art.

Status and Conservation

Tytonid owls reach their greatest diversity in the tropics, to which 12 of the 16 species are confined. Of the four ranging into higher latitudes, the Common Barn-owl occurs widely, while the African Grass-owl extends south to South Africa, and the Australian Masked-owl and the Greater Sooty-owl into southern and south-east Australia respectively. The Eastern Grass-owl is a marginal case, reaching the subtropical north of New South Wales in eastern Australia. Most research on tytonid owls has been centred on temperate populations, where a clearer picture of their status has emerged. Current knowledge of the status of tropical species varies considerably: for example, the Lesser Sooty-owl has now been

found to be abundant within its optimal habitat, whereas the Manus Masked-owl remains virtually unknown.

In the latest review of the world's threatened species, published in 1994, five species are listed as threatened: the Madagascar Red Owl is regarded as Endangered; and the Golden, Manus and Taliabu Masked-owls, as well as the Congo Bay-owl, are considered Vulnerable. To these it may be necessary to add the Lesser and the Minahassa Masked-owls, which are currently listed as Data-deficient, while the Lesser Sooty-owl appears as Near-threatened. Thus, only half of the world's tytonid species can really be considered in any way secure.

Recent fieldwork in the 1990's has led to the rediscovery of three of the rarest species, namely the Taliabu Masked-owl, the Madagascar Red Owl and the Congo Bay-owl, and indeed there are now recent records of all species except the Manus Masked-owl. All of the threatened species appear to be sensitive to habitat destruction, particularly the logging of tropical forest and its effect on the availability of nest-sites and food supply. The recent sightings are, of course, encouraging for the future of these owls, and have resulted from surveys targeted at the remaining areas of extant natural habitats that are known to be centres of avian endemism. Much of this work is co-ordinated through BirdLife International, and a great deal of useful information has been gathered on poorly known species. For the most elusive species, such as the Manus Masked-owl, the main problem for researchers is the inaccessibility of areas of likely occurrence, although this very factor has guarded such areas from human settlement and may prove to be crucial in ensuring the owls' continued survival.

The true rarity of owls can be difficult to assess until extensive survey work is undertaken. In south-east Australia, for example, Greater Sooty-owls and Australian Masked-owls are widespread and in places still occur at optimum levels in suitable, undisturbed habitats. With a clearer picture of their distribution emerging, genuine threats can be identified, particularly the significance of habitat disturbance, especially for sensitive species such as the Greater Sooty-owl. Surveys are also inval-

able in revealing evidence of declining numbers in some regions, as is the case with some populations of Australian Masked-owls.

Some owls that in certain areas are known to be rare and local, and affected by habitat disturbance, can be locally common elsewhere, often utilizing other habitat resources. For example, the Eastern Grass-owl is rare and declining over most of its range in Asia, but in Australia some populations have adapted to the boom-and-bust cycles of prey numbers in arid regions, and in parts of eastern Australia to agricultural changes such as the planting of cane fields supporting large rodent populations. The African Grass-owl is locally common within its range, but in some areas it is scarce, as a result of competition from Marsh Owls, as well as loss of suitable habitat, for instance in South Africa, where its numbers are declining.

The Oriental Bay-owl appears to be genuinely rare throughout its extensive range from Sri Lanka to Yunnan and then on to Borneo and Bali. Records have always been few, but, with no extended field studies of this species attempted to date, it may just be elusive in many areas. Nevertheless, the discovery in 1976 of a small population in south-west India suggests rarity as well as elusiveness in a region where much work had already been done. The lack of recent observations from many areas, for example in Bali, where it was last recorded in 1911, equally leads to the conclusion that it is, at any rate locally, a truly rare owl. It is a forest species, and is probably sensitive to disturbance when this affects nesting and roosting sites, as is also the case with sooty-owls. The far more restricted Congo Bay-owl is also rare, as well as highly localized. Several attempts to find it again following its initial discovery in 1951 were unsuccessful, until it was definitively relocated in the same region in 1996.

Those species extending into temperate regions have demonstrated some tolerance to habitat alteration, but, with the

exception of some races of the Common Barn-owl, such tolerance is limited, and is localized to a few areas. In Australia, the Greater Sooty-owl is considered the least tolerant owl species, and it has become a useful environmental indicator of the effects of disturbance in old-growth forest. The Australian Masked-owl occurs in a broader range of habitats, but is limited by the effects of change in habitat diversity and, consequently, on its hunting and breeding activities. The same can be said for the African Grass-owl, since its numbers in the south of its range are now declining as a consequence of increased habitat destruction.

The range expansion of the Common Barn-owl has been most remarkable, and appears to be limited only by winter temperatures of around zero or a few degrees below. This success has been linked with favourable habitat changes, notably in Europe and North America, through the opening-up of land for agriculture by an increasing human population, as well as gradual long-term warming at higher latitudes, although periods of harsher winters in northern Europe in the last 50 years and less favourable habitat changes in many areas have cut back some established populations. In North America, the species' northern breeding limit has expanded slightly over the last 50 years, reaching regions of southern Canada. While there are parts of its range where the Common Barn-owl is still expanding, it is also apparent that it has had a wide global range for a long time, as demonstrated by the fossil record.

Nevertheless, the status of this wide-ranging species varies from locally common to rare, according to the subspecies under consideration. Following on from the earlier expansion, northern temperate *alba* and *guttata* in Europe and *pratincola* in North America are currently in decline in many regions, and intensive conservation efforts have been required to try to stabilize and increase local populations. However, the extent of temperate popu-

It is easy to understand the long-established fascination that human beings have for owls.

This ranges across all cultures, and is perhaps most widely appreciated with regard to the Common Barn-owl.

This species' ghostly appearance and silent flight, the loud and eerie shrieking and hissing sounds it makes, and its largely nocturnal habits have earned it a myriad of names in the folklore of many languages.

These often betray an association in the human mind with witchcraft, magic and death, but in some areas the species is considered a lucky omen.

In later centuries, the Common Barn-owl's frequent presence in farmland and around villages added to the superstitions surrounding it, but in more recent times its particular liking for rodents has made it a welcome guest on farms, where it is regarded as a very effective "pest-controller".

Five of the 16 species of Tytonidae are currently listed as threatened. One of these is the Madagascar Red Owl, which is considered Endangered. Until very recently, there were very few records indeed of this striking owl, and nothing was known of its ecology or biology. Following intensive fieldwork in the 1990's, however, an individual was trapped in October 1994 and fitted with a radio transmitter. This enabled scientists to monitor its movements and to discover, for the first time, some facts about its life. In 1995, this bird nested and raised two young, one of which was then radio-tagged. The Madagascar Red Owls at this study site are to date the only ones to have been studied in the wild. The results have revealed that, among other things, the species inhabits forest edge, that it nests in tree cavities, and that it feeds on small native rodents and insectivores. It is obviously a very rare bird, and has probably always been so within its restricted known range; whether it does in fact have a wider distribution than is realized in Madagascar, but has been confused with the Common Barn-owl (*Tyto alba*), which is widespread on the island, is open to question. Whatever the true situation, the small area in which the species is known to occur is subject to habitat destruction on a scale sufficient to cause concern.

[*Tyto soumagnei*, near Ambanizana, Masoala Peninsula, north-east Madagascar. Photo: Russell Thorstrom]

Not discovered until 1951, the Congo Bay-owl eluded all subsequent attempts to locate it until 1996, when it was rediscovered in the same area in which it had originally been found. It is known from only a single locality in the Itombwe Massif, in easternmost Zaire, where both records have been from montane forest with patches of grassland and bamboo. Two unconfirmed records from sites c. 50 km away, in adjacent Rwanda and Burundi, give some hope that the owl may be slightly less rare than appears.

lation declines, and their causes and possible solutions, exhibit much regional variation. In contrast to the well-known temperate races, those of lower latitudes are relatively poorly known or quite unknown, and some of them are probably vulnerable, especially those confined to small islands or island groups, often amongst the most distinctive forms. For tropical races, the conservation concerns are the same as for other tropical tytonids, but as mere subspecies of the Common Barn-owl they have attracted less attention, although some may represent separate species (see Systematics). It is worth remembering that only relatively recently was the West Indian Ashy-faced Owl found to be a distinct species, rather than a race of the world's most widespread tytonid.

In both Europe and North America, prolonged and significant declines in Common Barn-owl populations began in many areas as early as the 1930's and 1940's, accelerating in the 1950's and 1960's. In North America, the range expansion of these owls into many areas followed European settlement with its associated forest clearance and agricultural development. Much the same pattern had occurred in much earlier times in Europe. Yet the recent decline of many populations began at around the same time in the two continents and is related to changing agricultural methods, with increasing mechanization, more intensive farming practices and, later, the introduction of organochlorine pesticides, which have now generally been replaced by anticoagulant rodenticides.

Increased efficiency of farming methods has reduced both the diversity and availability of foraging habitats and the numbers of rodents and other prey around storage facilities and other farm buildings. The latter are of particular value to the owls as sources of winter food. Fields have become larger, with the loss of edge habitats, while fertilizers and pesticides have removed the need to rotate crops, with the attendant loss of fallow grassland. Improvements in plant and animal breeding programmes have also reduced habitat variety. Nest-sites have been lost by the removal of natural tree sites and old buildings. The numbers of road-traffic casualties have risen dramatically as more and more roads have been built or extended and traffic speed has increased, particularly where roadside verges had become rich foraging sites.

Conservation programmes have paid special attention to the protection and re-establishment of the habitat mosaics preferred by the owls, with rough grassland, field margins and woodland edges to provide interconnected networks of prey-rich foraging grounds. The focus is on areas large enough not only to support breeding activity but also to ensure survival of as many birds as possible during winter periods, as well as to provide sufficient mobility to reduce possible inbreeding of local populations. The co-operation of farmers and other members of the rural communities is sought as an intrinsic part of the intensive management requirements, in order to sustain the long-term availability of suitable habitat. Where nest-sites have been reduced, nestboxes are provided. The types of box and their locations vary considerably, depending on the needs of particular populations and areas. As they are also used by other bird species, they must be closely monitored and maintained, and cleaned out afterwards, ready for the next nesting. Large numbers of boxes may be necessary simply to ensure that some are used by Common Barn-owls. At one English study site with 37 nestboxes, up to 19% were used for breeding and 47% for roosting, and over 13 years it was found that numbers had not increased but had stabilized; the owls had switched to these safer nest-sites, with the advantage of an increased fledging rate, while any surplus young probably moved to nearby areas.

Conservation programmes are also helped by the resilience of the Common Barn-owl. Mortality rates can be high, as much as 50% to over 70% in Europe, for example, but breeding starts in the first year of life, large clutches are laid, and the young grow rapidly. Losses are quickly replaced, so long as suitable foraging habitat and prey numbers are available. Captive breeding has also been successful, and it was estimated that in 1990, in Britain alone, there were 20,000-30,000 Common Barn-owls in captivity. However, while many of these captive-bred birds were intended for release in the wild, the policy of reintroducing this species is controversial. The effects on existing wild populations have caused some conflict, and the release of 2000-3000 birds annually from the early 1970's to 1992 resulted in high mortal-

ity, with only a few well-organized programmes leading to feral breeding. Since 1992, the release of captive-bred Common Barn-owls has been strictly controlled.

The inadequate regulation and control of rodenticide use is another major concern. While some positive steps are being taken to rectify this in Europe and North America, it has recently been found that Klerat, a second-generation anticoagulant rodenticide registered for use in cane fields in north-east Australia since 1992, has been a principal cause of the subsequent population crash of several species. Numbers of Common Barn-owls, Australian Masked-owls and Eastern Grass-owls, as well as other birds of prey, in that region have dropped by a staggering 75-85%. The effects of pesticides and rodenticides elsewhere urgently need further study, but the Australian case demonstrates the potentially dramatic effects on local populations.

Conservation successes for northern Common Barn-owl populations have resulted from a number of long-term studies. The methods employed may be adaptable to populations of these owls elsewhere, as well as to other *Tyto* species. Knowledge about most tytonid owls, however, currently remains far too sparse. For the tropical forms, as with other tropical bird families, the problems of habitat destruction, particularly the continuing logging of rainforest, together with the impact of human activities such as shooting and trapping, remain major concerns. Since owls are important indicators of the value and biodiversity of natural regions, their role in conservation programmes is of critical importance.

Most people may not see owls as often as they would like, but there can be very few who do not readily enjoy their appearance under a variety of circumstances. The mystery and magic of owls, as well as their importance in natural communities, are reason enough for every effort to be made to ensure their prosperous survival in the future.

Subfamily TYTONINAE

Genus *TYTO* Billberg, 1828

1. Greater Sooty-owl

Tyto tenebricosa

French: Effraie ombrée **German:** Rußeule **Spanish:** Lechuza Tenebrosa
Other common names: Sooty(!)/Black Owl, Dusky Barn-owl

Taxonomy. *Strix tenebricosus* Gould, 1845, River Clarence, New South Wales. Forms superspecies with *T. multipunctata*, and until 1981 treated as conspecific, but differs in size, plumage and voice; these two have occasionally been separated in genus *Megastrix*. Two subspecies recognized.

Subspecies and Distribution.

T. t. arfaki (Schlegel, 1879) - New Guinea and Yapen I.

T. t. tenebricosa (Gould, 1845) - SE Australia from Eungella National Park (EC Queensland) to Dandenong and Strzelecki Ranges (Victoria).

Descriptive notes. Male 37-43 cm, 500-700 g; female 44-51 cm, c. 875-1150 g (*tenebricosa*). When perched, large head and very short tail give "top-heavy" appearance. Darkest of all *Tyto* species, sooty-blackish with small silvery spots; very large black eyes in round facial disc; wings broad and rounded; legs densely feathered, large feet with strong talons. Female as male but larger (1 pair recorded where sizes reversed). Juvenile similar to adult. Race *arfaki* smaller, dark of underparts more variable. **VOICE.** Characteristic contact call a piercing, descending shriek, lasting c. 2 seconds, likened to sound of falling bomb ("bomb

whistle"); given in flight, with periods of minutes to hours between each call; also given in flight or perched by pair in duet-like performance. Other calls include high, piercing trill; also croaks, chirps, rasps, snores, squeals and wheezes, all associated with breeding activity; a screech similar to *T. novaehollandiae* occasionally heard. In New Guinea, descending shriek likened not only to falling bomb, but also to horse's neigh and to whistle of steam kettle. Juvenile utters "tearing calico" screech similar to *T. novaehollandiae* and *T. alba*.

Habitat. In Australia, favours deep, wet gully forest dominated by tall eucalypts, with substorey of rainforest trees and tree ferns, occurring in drier forest only to hunt; in New Guinea to 4000 m, in both lowland and montane rainforest, *Araucaria* pine forest, and recorded above tree-line in boulder-strewn alpine grassland and ridges, occurring in clearings and subalpine grassland only to hunt.

Food and Feeding. Unlike other *Tyto* species, arboreal mammals form bulk of diet, with terrestrial mammals and, rarely, small birds also taken. Size range of prey considerable: from ringtail possums (*Pseudocheirus*) weighing 900 g to mice (18 g); in New Guinea, large scrub-wallabies or pademelons (*Thylagale*) considered to have been taken as carrion. Prey species include gliders and pygmy-possums (Burramyidae/Petauridae), potoroos (*Potorous*), small wallabies (Macropodidae), bandicoots (Peramelidae), small dasyurid marsupials (*Antechinus*, *Sminthopsis*), forest bats, rabbits, large and small rats and mice; also ground thrushes (*Zoothera*), earwigs and beetles. Forequarters of mammals preferred, remainder often discarded; gape large, and skulls often swallowed whole. Hunts inside closed forest in tree tops and on trunks, but also captures prey on forest floor. Although in Australia less inclined to use low perches where ground cover broken, in New Guinea some apparently make regular use of open grassland at higher elevations. Male recorded hunting through forest canopy with female following behind but closer to forest floor, swooping on prey from perch or in flight. In disturbed habitats, particularly logged areas, ratio of terrestrial prey higher, with more hunting in open areas, including roadsides. Able to hunt in total darkness.

Breeding. Jan-Sept, most laying earlier, peaking around Apr. Single-brooded; may not nest each year. Appears to pair for life. Strongly territorial, territory size c. 200-800 ha; nest usually in large hollow of living tree, 0.5-5 m deep and at height of 10-50 m, also in rock crevices and caves, particularly large caves with nest cavity high above floor; some tree sites occupied for up to 9 years, and sites probably used for longer periods by same or several pairs; 1 cave site recorded as occupied for c. 10,000 years (based partly on analyses of accumulated debris, including remains of prey species long extinct in region); no nest made, but pellets and other debris may be used for egg placement. Clutch 1-2 eggs, usually 2, laid c. 4 days apart, usually with 1 chick surviving; incubation c. 35 days; natal down white to sooty-grey, second (mesopile) down sooty-grey; young fledges after c. 60 days, dependent on parents for further 4-5 months, usually returning to nest-site to roost for first few weeks. In captivity, greater reproductive potential has been noted: with ample food supply, can breed at any time, raise 2 broods per year with up to 3 young per brood, and breed when 1 year old.

Movements. Essentially sedentary. In Australia, movements of breeding pairs relate to habitat disturbance and fragmentation, particularly effect of reduced prey abundance. Juvenile post-breeding dispersal may account for a ringing recovery of a bird wandering 50 km, partly across cleared areas, though apparently unusual, as failure to disperse over open country may explain absence from suitable areas in W & C Victoria and lack of inland vagrant records. Recent records from EC Queensland, N of Conondale Range, indicate more N distribution limit than generally accepted, probably representing small, scattered resident populations rather than northward vagrancy. However, records from EC Queensland could still result from some dispersal of non-breeding birds. Old reports of occurrence on Flinders I, in Bass Strait, where species was considered resident; however, these records now considered erroneous, as referring to Morepork (*Ninox novaeseelandiae*).

Status and Conservation. Not globally threatened. CITES II. In Australia, not so much rare as seldom recorded. Recent results of surveys indicate a widely distributed owl probably at optimum levels in suitable habitat, but declining where habitat disturbed; in New South Wales, recent decline estimated at c. 20%. Total Australian population recently estimated at 2000-7000 pairs.

2. Lesser Sooty-owl

Tyto multipunctata

French: Effraie piquetée **German:** Fleckenrußeule **Spanish:** Lechuza Moteada
Other common names: Sooty Owl(!), Silver Owl

Taxonomy. *Tyto tenebricosa multipunctata* Mathews, 1912, Johnstone River, north Queensland. Forms superspecies with *T. tenebricosa*, and until 1981 treated as conspecific, but differs in size, plumage and voice; now usually recognized as separate species, though occurring between the ranges of the two races of *T. tenebricosa*; these two species have occasionally been separated in genus *Megastrix*. As recently as 1940, present species was considered not to differ even subspecifically from *T. t. tenebricosa*. Monotypic.

Distribution. NE Queensland, from Cedar Bay S to Paluma and inland to Windsor, Atherton and Evelyn Tablelands.

Descriptive notes. Male 31-35 cm, 430-450 g; female 35-38 cm, 540 g. Plumage silvery and blackish, paler below, upperparts and wing-coverts with numerous silvery spots; paler facial disc with very large, dark eyes; short tail. Smaller and paler than *T. tenebricosa*, upperparts more densely spotted, and underparts lighter, silvery white with pattern of dark chevrons on pale background, especially on breast; legs and feet proportionately smaller. Sexes similar, including foot proportions. Juvenile similar to adult. **VOICE.** Calls similar to *T. tenebricosa* but higher-pitched, thinner and more penetrating, and birds generally noisier.

Piercing, downscale "bomb whistle" contact call, often with slight step in smooth downward progression, given in flight and when perched, usually when approaching nest with food and when leaving nest area.

Habitat. Rainforest, mainly above 300 m, rarely to sea-level, occurring in disturbed habitats and clearings only to hunt.

Food and Feeding. Prey includes pygmy-possums and small gliders (Burramyidae/Petauridae), and small dasyurid marsupials; arboreal and particularly terrestrial rodents, including water rats (*Hydromys*); medium-sized forest birds, including catbirds (*Ailuroedus*, *Scenopoeetes*), riflebirds (*Ptiloris*) and chowchillas (*Orthonyx*); and beetles and earwigs. Like *T. tenebricosa* is an efficient hunter within closed forest, but making greater use of low perches, commonly sides of tree trunks, and taking more prey on ground; also uses rainforest tracks and clearings. Able to hunt in total darkness and during heavy rainfall.

Breeding. Dates variable, depending on rainfall; eggs can be laid in any month, mostly Mar-May; territorial pairs may miss a season if conditions unfavourable. Nest-site usually large hollow, up to c. 40 m above ground, in trunk or main limb of living tree, commonly *Eucalyptus grandis*, but recently found also to use several species of rainforest tree, e.g. crevice in strangler fig (*Ficus*); depth of hollow varies from level with entrance to several metres deep; no nest made, eggs laid on pellet and other debris. Clutch usually 2 eggs, occasionally 1; incubation c. 40-42 days; natal down white to sooty-grey, second (mesopile) down sooty-grey; young fledge after c. 90 days, known to remain in breeding territory for at least several weeks.

Movements. Sedentary. Post-breeding dispersal of juveniles may explain lower-altitude and off-shore sightings. Vagrant to Hinchinbrook I. Recent report of record from W New Guinea an error for *T. tenebricosa*.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Queensland Wet Tropics EBA. Currently considered Near-threatened. Within total world range of c. 4000 km², population recently estimated at c. 2000 breeding pairs. Abundant within optimal habitat; territories as small as 50 ha, some nests only c. 400 m apart.

Bibliography. Anon. (1994g), Barker & Vestjens (1989), Blakers *et al.* (1984), Britton (1990a, 1990b, 1991), Burnett *et al.* (1996), Christidis & Boles (1994), Condon (1975), Fleay (1979, 1981), Garnett (1993), Higgins (1999), Hollands (1991, 1995), Lindsey (1992), Macdonald (1988), Mathews (1912a, 1916), Mees (1964), Olsen (1998), Palliser (1985), Pizzey & Doyle (1998), Pizzey & Knight (1997), Rothschild & Hartert (1913), Schodde & Mason (1981, 1997), Schodde & Tidemann (1986), Simpson & Day (1998), Stattersfield *et al.* (1998), Stewart (1984), Storr (1984), Strahan (1994), Trounson & Trounson (1987), Whittle (1994).

3. Australian Masked-owl

Tyto novaehollandiae

French: Effraie masquée **German:** Neuhollandeule **Spanish:** Lechuza Australiana
Other common names: Chestnut-faced/Maw-faced/Masked/Cave Owl; New Guinea Masked-owl (*calabyi*); Tasmanian Masked-owl/Owl (*castanops*)

Taxonomy. *Strix*? *Nova Hollandiae* Stephens, 1826, New South Wales.

Forms superspecies with *T. aurantia*, *T. manusi*, *T. sororcula*, *T. nigrobrunnea* and *T. inexpectata*. Some authors treat *T. sororcula* and *T. manusi* as conspecific with present species, and in part most of the above allopecies were lumped into present species. Race *castanops* often treated as separate species, but recent review of size and colour variation within S Australian populations supports

inclusion within present species, at subspecific level. New Guinea population *calabyi* has been proposed to constitute a megasubspecies, but again differences do not seem sufficiently marked. Race *galei* sometimes merged with *kimberli*, as observed differences may not be consistent and few specimens have been used in analyses. Birds of SW Western Australia may merit separation as distinct race, due to significantly larger size, but more study needed; formerly separated in race *perplexa*. Cave-dwelling population of South Australia might be separable as race *troughtoni*, but remains very poorly known. Six subspecies currently recognized.

Subspecies and Distribution.

T. n. calabyi Mason, 1983 - S New Guinea, in S Trans-Fly region, from Merauke area to Tarara and Daru I.

T. n. melvillensis Mathews, 1912 - Melville I and Bathurst I (off N Australia).

T. n. galei Mathews, 1914 - NE Cape York Peninsula in NE Queensland, from Pascoe R to Chester R. *T. n. kimberli* Mathews, 1912 - N Australia from Yampi Peninsula E to S Cape York Peninsula and Atherton Tablelands.

T. n. novaehollandiae (Stephens, 1826) - SW Western Australia E to Victoria and N to NE Queensland (Townsville), mainly in discontinuous and coastal distribution, but also scattered inland records, mostly from E Australia.

T. n. castanops (Gould, 1837) - Tasmania and Maria I; also Maatsuyker I, where perhaps only vagrant. Introduced (*castanops*) to Lord Howe I.

Descriptive notes. Male 33-42 cm, 420-800 g; female 38-57 cm, 545-1260 g. Occurs in dark and light colour morphs, with variation within each, and with intermediates. Dark morph has upperparts blackish-brown, washed rufous and speckled white, underparts pale rufous, coarsely spotted dark, and facial disc dark chestnut; light morph has upperparts pale grey, washed yellow and speckled dark and white, underparts white, sparsely grey-flecked, and facial disc white. Light morph confusable with *T. alba*, but often more distinctly spotted below, with rounder and more strongly margined facial disc, more densely feathered and heavier legs, larger feet

with massive talons, and stronger and more purposeful flight (unlike lighter, slightly erratic flight of *T. alba*); *T. longimembris* has longer legs with protruding feet in flight, longer wings, more heart-shaped facial disc, black and orange upperparts and terrestrial habits. Female always much bigger than male and sometimes twice as heavy. Juvenile similar to adult or more heavily spotted. Nomininate race generally dark morph or intermediate; *castanops* female always dark, while male may have paler, but never white, breast; *kimberli* generally light or intermediate; largest birds in Tasmania (female largest of all congeners), averaging smaller northwards, *galei* smallest; *melvillensis* also small and apparently all dark or intermediate; *calabyi* as dark on upperparts as nominate, with larger legs, and wings paler, like *galei*, but longer. **Voice.** Various calls, mostly associated with breeding, include cackles, chatters, shrieks, rasps, squeals and hisses; richer, louder and deeper than those of *T. alba*. Characteristic is a very loud, shrill scream, lasting 1-2 seconds, given once only soon after dusk, usually in flight, after leaving nest-site, but variations may be given 1-4 hours after dusk, or similar calls of longer duration by male during circling courtship flight.

Habitat. Usually associated with tall open forest dominated by big trees suitable for nesting and roosting; unlike *T. tenebrosica*, favours sites with access to more open areas. More numerous where greatest local forest and woodland diversity occurs, i.e. forest types with dry, open understorey, providing variety of dense and sparse ground cover. Smaller numbers patchily distributed away from coastal regions in wooded farmland, riparian woodland and isolated stands of large trees; also pine plantations, and in N Australia *Melaleuca* swamps and mangrove edges; in S Australia, relict population has adapted to treeless plains, using caves and rock clefts for nesting and roosting.

Food and Feeding. As for *T. tenebrosica*, wide weight range of prey from large possums to mice. Includes possums (*Trichosurus*, *Pseudocheirus*), gliders and pygmy-possums (*Burrardidae*/Petauridae), potoroos (*Potorous*), bandicoots (*Peramelidae*), dasyurid marsupials, rabbits, rats and mice; also records of domestic fowl, kookaburras (*Dacelo*), Australian magpies (*Gymnorhina*), House Sparrows (*Passer domesticus*), reptiles, beetles and large moths. While some arboreal species taken, most prey captured on ground, by hunting both on wing and from perches; after dusk, changes from low hunting flights over open ground to perch-hunting.

Breeding. May breed at any time of year; most eggs laid Mar-Jul, N birds earlier, Tasmanian birds later. Apparently territorial, pair-members may stay together all year; in SE Australia, estimated territory size c. 1000-1200 ha; nest-site a large hollow 40-500 cm deep in living or dead tree, at height of 12-25 m, usually in trunk but also in vertical branch spout; favours isolated trees or trees higher than surrounding ones, with same sites used for many years (over 20 kg of pellet material removed from 1 site); in Nullarbor Plain region of S Australia, nesting recorded on cliff ledge and in cleft of caves; no nest constructed, but few instances of male making depression in debris in hollow and once even adding a few sprigs of eucalypt leaves. Clutch 2-4 eggs, usually 2; incubation 35-42 days; natal down white, second (mesopile) down creamy; young fledge after 10-12 weeks, still with traces of down, stay near nest for several weeks, repeatedly calling at night for food, and may use nest as daytime roost.

Movements. Sedentary. Only movements may be post-breeding dispersal of juveniles, and opportunistic exploitation by adults of recently disturbed habitats or changes in prey abundance, including rodent plagues, but not to extent of *T. alba* and *T. longimembris*. In SW Australia, some records attributed to seasonal movements but possibly due to post-breeding dispersal or unrecorded breeding.

Status and Conservation. Not globally threatened. CITES II. Breeding pairs found at 1-10 km intervals, and in N Queensland 5 pairs within 30 km; recent surveys in SE Australia have demonstrated wider range and incidence of records, though in New South Wales population has halved and in Victoria only 300-400 breeding pairs estimated to remain. Status of "Cave Owl" population of Nullarbor Plain unknown, but probably very few, if any, remain; decline possibly result not only of human persecution and loss of prey species earlier in 20th century, but also of competition with *T. alba*; latter also widely recorded from Nullarbor region and current status there also unknown, but remains of both species found at same site in 1984 (and evidence of diets) suggests that some degree of niche overlap may account for presence of both owls. Still widespread in Tasmania, but numbers declining; probably only vagrant on Maatsuyker I. Apparent rarity in SW Australia may be due to under-sampling. In N Queensland, rodenticides used since 1992 for rat control in cane fields have caused local population declines of 75-85%.

Bibliography. Baker-Gabb (1993), Barker & Vextjens (1989), Beehler *et al.* (1986), Beruldsen (1980), Blackhall (1995), Blakers *et al.* (1984), Bright (1992), Britton (1990a, 1990b, 1991, 1992), Carter (1977), Christidis & Boles (1994), Clark *et al.* (1978), Coates (1985), Collins (1995), Condon (1975), Cooper & McAllan (1995), Davey (1993), Debus (1990, 1993a, 1993b, 1994a, 1995, 1997a, 1997c), Debus & Rose (1994), Emison *et al.* (1987), Fleay (1949, 1979, 1981), Ford (1968, 1986), Francis (1992), Fullager *et al.* (1974), Garnett (1993), Green, R.H. (1979), White (1985), Young & De Lai (1997).

4. Golden Masked-owl

Tyto aurantia

French: Effraie dorée

German: Goldeule

Spanish: Lechuza Dorada

Other common names: Bismarck Masked-owl, Golden Owl, Golden/New Britain Barn-owl

Taxonomy. *Strix aurantia* Salvadori, 1881, New Britain.

Forms superspecies with *T. novaehollandiae*, *T. manusi*, *T. sororcula*, *T. nigrobrunnea* and *T. inexpectata*. Monotypic.

Distribution. New Britain.

Descriptive notes. 27-33 cm. Distinguished from other masked-owls by its golden-buff plumage, darker above, paler below, with blackish-brown mottling. Female similar to male but larger. Juvenile undescribed. **Voice.** Calls attributed to this owl are a "ka-ka", repeated c. 6 times per second and ascending slightly, and a long ascending whistle heard at night at same locality.

Habitat. Rainforest, from lowlands to c. 1830 m.

Food and Feeding. Stomach of 1 specimen contained a small rodent.

Breeding. Undescribed.

Movements. Presumably sedentary.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in New Britain and New Ireland EBA. Considered rare, with few recent field records, including sightings in 1978 and 1984 in forest-edge habitat. Species is probably adversely affected by continuing forest destruction. Research and census work urgently required.

Bibliography. Clark *et al.* (1978), Coates (1985), Collar & Andrew (1988), Collar *et al.* (1994), Gilliard & LeCroy (1967a), Gurney (1882, 1894), Meyer (1934), Salvadori (1881), Schodde (1978), Stattersfield *et al.* (1998).

5. Manus Masked-owl

Tyto manusi

French: Effraie de Manus

German: Manuseule

Spanish: Lechuza de la Manus

Other common names: Manus Owl, Admiralty Islands Masked-owl

Taxonomy. *Tyto manusi* Rothschild & Hartert, 1914, Manus, Admiralty Islands.

Forms superspecies with *T. novaehollandiae*, *T. aurantia*, *T. sororcula*, *T. nigrobrunnea* and *T. inexpectata*. Sometimes considered conspecific with *T. novaehollandiae*. Evidence of extinct populations from Mussau and New Ireland may refer to undescribed races of present or closely related species, perhaps also isolated on single islands, and suggests that masked-owls may once have occurred more widely in Bismarck Archipelago. Monotypic.

Distribution. Manus I, in Admiralty Is.

Descriptive notes. c. 33 cm. Distinguished from other masked-owls by combination of dark upperparts, rufescent brownish buff underparts with large blackish spots, and black tail with narrow, irregular, yellowish-brown bars. Type specimen, collected 1913, is male with wing 275 mm, compared with second known specimen, a female with wing 301 mm, indicating that, as with other masked-owls, female is larger than male. Juvenile plumage undescribed. **Voice.** Undescribed.

Habitat. Rainforest; perhaps confined to hilly terrain at higher elevations (Manus I reaches 702 m).

Food and Feeding. Undescribed.

Breeding. Undescribed.

Movements. Presumably sedentary.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in Admiralty Islands EBA. No recent records. Failure to find this owl during a 1990 survey suggests that it is confined to areas away from human settlement (not visited during survey), possibly explaining its unfamiliarity to local inhabitants, who occupy coastal areas, access inland being limited to a single road in E Manus. Type specimen was collected near a coastal settlement, suggesting population decline since 1913, although numbers probably always small. Further research and census work required.

Bibliography. Buckingham *et al.* (1995), Coates (1985), Collar *et al.* (1994), Dutson & Newman (1991), Rothschild & Hartert (1914), Stattersfield *et al.* (1998), Steadman & Kirch (1998), Stresemann (1933, 1934).

6. Lesser Masked-owl

Tyto sororcula

French: Effraie des Tanimbar

German: Molukkeneule

Spanish: Lechuza de las Tanimbar

Other common names: Tanimbar Owl

Taxonomy. *Strix sororcula* P. L. Selater, 1883, Larat, Tanimbar Islands.

Forms superspecies with *T. novaehollandiae*, *T. aurantia*, *T. manusi*, *T. nigrobrunnea* and *T. inexpectata*. Sometimes treated as conspecific with *T. novaehollandiae*. Race *cayeli* may repre-

sent a separate species; Seram population may represent an undescribed race. Species name often misspelt *sororcula*. Two subspecies recognized.

Subspecies and Distribution.

T. s. cayellii (Hartert, 1900) - Buru; also Seram (probably this race).

T. s. sororcula (P. L. Slater, 1883) - Tanimbar Is (Larat, Yamdena).

Descriptive notes. c. 29-31 cm. Nominate race is smallest member of masked-owl group; upperparts brownish, mottled white, underparts whitish with dark spotting on sides, and pale legs covered only with flesh-coloured bristles. Female apparently as male but larger. Juvenile undescribed. Race *cayellii* averages slightly larger, and is generally more tawny buff over all of plumage; upperparts more blackish, mottled brownish, with white mottling only on wing-coverts, and narrowly black-barred yellowish-brown tail. **VOICE.** Undescribed.

Habitat. Presumably rainforest (Buru, Seram) and primary and mature secondary monsoon

forest (Tanimbar).

Food and Feeding. Undescribed.

Breeding. Undescribed.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Banda Sea Islands EBA and Buru EBA. Data-deficient. Apparently rare, and no current data on numbers or localities. On Buru, lowland areas cited by collectors of 2 extant specimens. Kaleji Bay (1889) and Wae Eno (1921), now much altered and doubtless unsuitable; while a 1989 survey did not record this species, additional surveys are under way on Buru and new data may soon be forthcoming. Also, no precise locality for 2 specimens known from Tanimbar Is (1882 and 1923), but apparently suitable habitat still extensive; although 1985 and 1993 surveys on Yamdena failed to locate this owl, it was sighted there in late 1995, and a proposal for an integrated conservation and development project on Yamdena is currently being assessed. Details of a *Tyto* owl discovered on Seram in 1987 hitherto limited to photographic evidence, and exact identity remains to be determined, but it probably represents an undescribed subspecies of present species.

Bibliography. Andrew (1992), Anon. (1996e), Bishop (1989), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Hartert (1929), Inskipp *et al.* (1996), Isherwood *et al.* (1998), Monk *et al.* (1997), Poole (1996), Siebers (1930), Stattersfield *et al.* (1998), Stresemann (1933, 1934), Sujatnika *et al.* (1995), White & Bruce (1986).

7. Taliabu Masked-owl

Tyto nigrobrunnea

French: Effraie de Taliabu

German: Taliabueule

Spanish: Lechuza de la Taliabu

Other common names: Taliabu Owl/Barn-owl, Sula Owl/Masked-owl, Black-brown Owl

Taxonomy. *Tyto nigrobrunnea* Neumann, 1939, Taliabu, Sula Islands.

Forms superspecies with *T. novaehollandiae*, *T. aurantia*, *T. manusi*, *T. sororcula* and *T. inexpectata*. Until recently, often considered conspecific with *T. inexpectata*. Monotypic.

Distribution. Taliabu, in Sula Is.

Descriptive notes. c. 32 cm. Male unknown, presumably similar to female. Unique type specimen, female, has upperparts dark brown with lines of small white spots, wings and tail dark brown with no bars; facial disc pinkish-brown, darker around eyes; underparts golden-brown, thinly vermiculated with black and covered with black spots. Juvenile unknown. **VOICE.** Undescribed.

Habitat. Presumably rainforest; also sighted recently in selectively logged lowland forest, which perhaps enters only to hunt.

Food and Feeding. Undescribed.

Breeding. Undescribed.

Movements. Presumably sedentary.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in Banggai and Sula Islands EBA. Presumed to be scarce; a few recent sight records, including 1 standing on a dirt road. Effects of ongoing habitat destruction unknown. No existing protected areas in Sula Is, where remaining forest covered by timber concessions. Research and census work urgently required.

Bibliography. Andrew (1992), Bishop (1989), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Davidson *et al.* (1995), Eck & Busse (1973), Holmes & Philipps (1996), Inskipp *et al.* (1996), Monk *et al.* (1997), Neumann (1939), Stattersfield *et al.* (1998), Stones, Davidson & Raharjaningirah (1997), Sujatnika *et al.* (1995), White & Bruce (1986).

8. Minahassa Masked-owl

Tyto inexpectata

French: Effraie de Minahassa

German: Minahassaeule

Spanish: Lechuza de Minahassa

Other common names: Minahassa/Unexpected Owl/Barn-owl

Taxonomy. *Strix inexpectata* Schlegel, 1879, Minahassa, Sulawesi.

Forms superspecies with *T. novaehollandiae*, *T. aurantia*, *T. manusi*, *T. sororcula* and *T. nigrobrunnea*. Until recently, widely considered to include *T. nigrobrunnea* as a race. Species name often misspelt *inexpectata*. Monotypic.

Distribution. N & NC Sulawesi.

Descriptive notes. c. 30 cm. Upperparts mixed black and rusty with no white speckling or spotting, wings barred black and rufous; facial disc tinged light rusty; underparts light rusty with variable black spotting. Differs from *T. alba* in smaller size, slimmer shape, smaller facial disc in relation to body size. Juvenile apparently has browner wings, and underparts greyish-white and speckled. **VOICE.** Described as similar to that of *T. rosenbergii* but weaker and less deep.

Habitat. Primary and lightly disturbed hill and lower montane forest and disturbed riverine forest, occasionally forest edge, at 100-1500 m.

Food and Feeding. Undescribed.

Breeding. Evidence of breeding in early Apr; juvenile apparently being fed by adults in early to middle Sept 1995. One probable nest hole was in *Elmerrillia* tree; fledged juvenile was attended by adults c. 25 m up in strangler-fig tree.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Sulawesi EBA. Data-deficient. Known only from 11 specimens and 3 sightings from 5 localities, all but 1 from N Sulawesi; only other locality is in Lore Lindu National Park S of Palu at 675 m, where a specimen was found dead in Nov 1980. Original source localities of most specimens greatly altered and presumably no longer contain suitable habitat, though later records indicate populations in more secure forest areas, notably Dumoga-Bone National Park. Sparsely distributed and rare, or just overlooked; perhaps locally common where its optimal habitat can be surveyed.

Bibliography. Andrew (1992), Andrew & Holmes (1990), Bishop (1989), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Fletcher (1998), Holmes & Philipps (1996), Inskipp *et al.* (1996), van Marle (1940), Rozendaal & Dekker (1989), Stattersfield *et al.* (1998), Stresemann (1940), Sujatnika *et al.* (1995), Watling (1983), White & Bruce (1986), Whitten *et al.* (1987).

9. Sulawesi Owl

Tyto rosenbergii

French: Effraie des Célèbes

German: Sulawesieule

Spanish: Lechuza de Célebes

Other common names: Sulawesi/Celebes Masked-owl/Barn-owl, Rosenberg's Owl/Barn-owl, Celebes Owl

Taxonomy. *Strix rosenbergii* Schlegel, 1866, Modelido, Boni and Gorontalo, Sulawesi.

Recently considered part of masked-owl group, but apparently more closely related to *T. alba*. Race *pelengensis* frequently misspelt "*pelelensis*". Two subspecies recognized.

Subspecies and Distribution.

T. r. rosenbergii (Schlegel, 1866) - Sulawesi and Sangihe.

T. r. pelengensis Neumann, 1939 - Banggai Is (Peleng).

Descriptive notes. 43-46 cm. Male upperparts dark blackish-grey with white speckling and white spots; facial disc dusky white to brownish; underparts buffy with blackish spots and darker feather edges; tail with 5 black bars. Female darker, with heavier spotting on underparts, which tends to form bars. Juvenile undescribed. Race *pelengensis* markedly smaller, with broken black feather edges on chest, giving scaly appearance. **VOICE.** A very hoarse, dry screech with slight hissing quality, usually given in flight; eerie, long, shrill "skkeear" uttered occasionally when hunting at or after dusk.

Habitat. Lightly wooded cultivation, tall dead trees in open country, grassland, forest edge and young coconut plantations; occasionally around villages and urban areas; from sea-level to 1200 m. Hunts over clearings and cultivation, forest edge, and after dark along roads; rarely seen during day.

Food and Feeding. Recorded feeding on rats; pellets collected in a cave chamber on Sulawesi and attributed to present species contained rats, shrews and a bat (*Hipposideros*), and evidence of possible nestling cannibalism.

Breeding. Undescribed.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Widespread but generally uncommon in Sulawesi, though fairly common locally in Palu Valley; present in Dumoga-Bone National Park. Status on Sangihe and Peleng unknown. Research and survey work required.

Bibliography. Andrew (1992), Andrew & Holmes (1990), Catterall (1997), Coates & Bishop (1997), Coomans de Ruiter & Maurenbrecher (1948), Hartert (1929), Holmes & Philipps (1996), Inskipp *et al.* (1996), Neumann (1939), Riley (1997a), Rozendaal & Dekker (1989), Schlegel (1866), Sharpe (1875, 1876), Stresemann (1940), Watling (1983), White & Bruce (1986), Whitten *et al.* (1987).

10. Common Barn-owl

Tyto alba

French: Effraie des clochers **German:** Schleiereule **Spanish:** Lechuza Común
Other common names: Barn Owl, Lesser Masked-owl(!), Monkey-faced Owl, Cave/Death/Delicate/Demon/Ghost/Golden/Hissing/Night/Screech/Silver/White Owl; Eastern/Australian Barn-owl (*delicatula*); Galapagos Barn-owl (*punctatissima*)

Taxonomy. *Strix alba* Scopoli, 1769, Friuli, Italy. Up to 46 races recognized in recent works, but status and distribution of several uncertain, and review of whole group long overdue. West Indian taxa *glaucoops*, *insularis* and *nigrescens* formerly included in present species, now shown to be separate species. *T. glaucoops*; some authors separate only *glaucoops*, retaining other two races in present species. Considerable variation in size and colour may be more individual than geographical in many continental and some island regions, with possibly expanding zones of intergradation, particularly in Europe. Nominate and *guttata* intergrade from Netherlands, Belgium and N & E France to Germany (Rhine Valley) and C Switzerland; nominate intergrades with *affinis* in region of S Egypt and N Sudan. Validity of many proposed races considered too doubtful to be upheld: in Europe, *pusilla*, *kleinschmidt*, *kirchhoffi* and *hostilis* merged with nominate, and *rhena* with *guttata*; Madagascan *hypermetra* with African *affinis*; island populations *everetti*, *kuehni*, *bellonae*, *lifuensis* and *lulu* with widespread Australasian *delicatula*; Bahamian *luayana* with *pratincola*; and, in Neotropics, Colombian *subandana* with *guatemalae*, *stictica* with *contempta* and *hauchecornei* with *tuidara*. Also, current separation of *niveicauda* from *furcata* (based on colour characters) and of *guatemalae* from *pratincola* (ranges in Central America not yet satisfactorily determined) perhaps doubtful, and continued separation of *bondii* may not be tenable; size and colour variation in Neotropics in need of reassessment, and separation of *hellmayri* from *tuidara* based on size characters questionable. Furthermore, *poensis* possibly not separable from *affinis*, in which case *poensis* (as older name) has priority over latter. N African nominate race birds sometimes placed in *erlangeri*; birds from S Myanmar to Indochina sometimes placed in *javanica*, but seem better included in *stertens*. Melanesian populations, currently covered by 3 races (*delicatula*, *crassirostris*, *interposita*), may merit further splits. Several well-marked insular races (e.g. *detorta*, *thomensis*, *deroepstorffii*, *punctatissima* and possibly others) may be separate species; recent proposals to elevate *delicatula* to species level (see page 36), however, do not consider which races it would include. Twenty-eight subspecies currently recognized.

Subspecies and Distribution.

T. a. alba (Scopoli, 1769) - W & S Europe (including Balearic Is and Sicily) to N Turkey; also W Canary Is (Tenerife, Gran Canaria, El Hierro), and N Africa from Morocco to Egypt (except Sinai), S to N Mauritania, S Algeria, Niger (Air Massif) and NE Sudan.
T. a. guttata (C. L. Brehm, 1831) - C Europe E to Latvia, Lithuania and Ukraine, and SE to Albania, Macedonia, Romania and NE Greece.
T. a. ernesti (Kleinschmidt, 1901) - Sardinia and Corsica.
T. a. erlangeri W. L. Slater, 1921 - Crete and smaller S Greek islands, Cyprus and patchily from Syria E to SW Iran and S to NE Egypt (Sinai) and S Arabian Peninsula.
T. a. schmitzi (Hartert, 1900) - Madeira and Porto Santo.
T. a. graciliorstris (Hartert, 1905) - E Canary Is (Fuerteventura, Lanzarote, Lobos, Montaña Clara, Alegranza).
T. a. detorta Hartert, 1913 - Cape Verde Is.
T. a. affinis (Blyth, 1862) - Africa S from S edge of Sahara, including Zanzibar and Pemba, and Madagascar and Comoro Is.
T. a. poensis (Fraser, 1842) - Bioko I.
T. a. thomensis (Hartlaub, 1852) - São Tomé I; recorded in error from Príncipe I.
T. a. stertens Hartert, 1929 - Indian Subcontinent S to N Sri Lanka, and E to SC China (Yunnan), Vietnam and S Thailand.
T. a. deroepstorffii (Hume, 1875) - S Andaman Is.
T. a. javanica (J. F. Gmelin, 1788) - Malay Peninsula S to Greater Sundas (including Krakatau, Pulau Seribu and Kangean Is, and possibly S Borneo) and E to Alor, as well as Tanahjampea, Kalao and Kalaotoa.
T. a. sumbaensis (Hartert, 1897) - Sumba I.
T. a. meeki (Rothschild & Hartert, 1907) - E New Guinea and nearby islands of Manam and Karkar.
T. a. delicatula (Gould, 1837) - Sawu, Roti(?), Timor, Jacor, Wetar, Kisar and Tanimbar Is; Australia and offshore islands; Long I and possibly N New Britain and New Ireland; also Nissan, Buka, Solomon Is (including Bougainville), S Vanuatu (Erromanga, Tanna, Aneityum), New Caledonia, Loyalty Is, Fiji (N to Rotuma), Tonga (N to Niao'ou), Wallis and Futuna Is, Niue I, Western Samoa and Samoa.
T. a. crassirostris Mayr, 1935 - Tanga Is (E Bismarck Archipelago).
T. a. interposita Mayr, 1935 - Santa Cruz Is, Banks Is, N Vanuatu (S to Efate).
T. a. pratincola (Bonaparte, 1838) - S Canada S at least to Mexico; also Bermuda, Bahamas and Hispaniola.
T. a. guatemalae (Ridgway, 1874) - Guatemala and perhaps S Mexico to Panama (including Pearl Is), possibly to W Colombia.
T. a. bondii Parkes & Phillips, 1978 - Bay Is (Roatán, Guanaja), off N Honduras.
T. a. furcata (Temminck, 1827) - Cuba, Cayman Is and Jamaica.
T. a. niveicauda Parkes & Phillips, 1978 - I of Pines.
T. a. bargei (Hartert, 1892) - Curaçao, and possibly also Bonaire.
T. a. punctatissima (G. R. Gray, 1838) - Galapagos Is.
T. a. contempta (Hartert, 1898) - W Venezuela, Colombia (except W?), Ecuador and Peru.
T. a. hellmayri Griscom & Greenway, 1937 - E Venezuela (including Margarita I) through the Guianas to N Brazil (S to Amazon); also Trinidad and Tobago.
T. a. tuidara (J. E. Gray, 1829) - Brazil (S of Amazon) S to Tierra del Fuego and Falkland Is. Introduced (*affinis*) to Seychelles; also (*delicatula*, *pratincola*) to Lord Howe I, where now presumed extirpated (few records since 1970's considered vagrants); also (*pratincola*) to Hawaii.
Descriptive notes. 29-44 cm; 187-455 g (Europe, N Africa), 266-470 g (S Africa), 400-700 g (North America), 387-558 g (Surinam), 264 g (Galapagos Is); male av. 555 g, female av. 612 g (Malaysia); male 227-418 g, female 220-475 g (Australia). Medium-sized, long-legged owl with distinctive heart-shaped face. Nominative race golden-buff above, with variable light greyish "veil", and finely streaked, mottled and dotted dark; white facial disc and underparts, sometimes with pale buff on sides of chest and/or fine spotting on breast and flanks; legs densely feathered; eyes dark; buoyant, slow, wavering flight, with legs dangling, appears ghost-like. No similar owl over much of range (but in Afrotropics race *affinis* overlaps with *T. capensis* and from India to Australia *stertens* and *delicatula* with *T. longimembris*, both those species longer-legged and usually notably darker, also in Australia with *T. novaehollandiae*, which usually larger and darker but some more like present species). Female like

male, tends to be slightly darker. Juvenile similar to adult, or more heavily spotted. Racial variation considerable, from light grey to buff above and from white to buff below, with varying amount of black spotting and speckling, but widespread intergradation (common in Europe and tropical regions), and island races tending to be smaller and with either whiter or buffier plumage (but some isolated, dark tropical island races): *guttata* grey, sometimes buff-washed, above, buff (male) to rufous-buff (female) and usually spotted below; *ernesti* pale and white-breasted; *erlangeri* also white-breasted, but upperparts more golden; *schmitzi*, *graciliorstris* and *detorta* buff-breasted, darkest in *detorta*; *affinis* greyer above than nominate, with more and coarser spotting below; *poensis* similar, but darker above, more golden-buff and streaked and speckled black and white, primaries barred and tail buffier; *thomensis* smaller, much darker, dark grey above with conspicuous small black and white spots, golden-brown below; *stertens* pale and greyish above, with small spots on pale underparts; *javanica* similar but more golden-buff above, larger spots below; *deroepstorffii* smaller, darker, with dark brown upperparts, deep brownish-rufous underparts; *sumbaensis* slightly larger than *javanica*, larger bill, almost white tail with narrow black bars; *meeki* like *sumbaensis* but tail bars paler, bill smaller, underparts silvery-white with arrow-shaped dusky spots; *delicatula* like *javanica*, but brownish-grey to light grey above, mottled pale brown with slight tawny tint, white below, 4 brown bars on tail; *crassirostris* darker, bill and feet more robust; *interposita* washed orange-ochre; *pratincola* upperparts vary from pale orange-buff to lighter or darker grey mixed with orange-buff, underparts white to pale orange, spotted or vermiculated brown (similar to European birds but larger, with stronger legs and feet); *guatemalae* like darker *pratincola*, but more uniform above, more coarsely speckled below (extent of differentiation from *pratincola* indeterminate); *bondii* apparently smaller and paler than *pratincola*; *furcata* pale orange-buff above with greyish-brown spots, white below with few flank spots; *niveicauda* averaging whiter and paler than *furcata*; *bargei* like nominate, but smaller, with shorter wings; *punctatissima* small, dull brown above with few scattered dusky white spots, golden-buff to white below with brownish vermiculations or fine dense spots; *contempta* black above with fine pale grey mottling and white spots at feather tips, pale rusty-brown below with irregular black cross-markings, but characters variable; *hellmayri* larger than *tuidara*, both dark to pale yellowish above and near-white to golden-buff below, with or without dusky spotting. VOICE. Diverse range of calls associated with breeding, including screeches, wheezes, purrs, snores, twitters, hisses and yelps; less vocal at other times; also bill-snapping, tongue-clicking and wing-clapping. Male's familiar screech, considered advertising or warning call, usually given in flight, a hoarse, screaming, eerie "shrrreeeee" with gargling or rattling quality and tremulous effect (from wing action), of c. 2-3 seconds' duration, repeated after 1-20 seconds, often many in series, but usually singly when patrolling territory; female's variant lower-pitched, more broken, especially when both call during aerial chases. Variations of other loud screams and screeches attributed to mobbing response or distress behaviour.

Habitat. Occurs in great variety of habitats according to availability of prey, seasonality in temperate regions, and competition from other predators; in higher latitudes limited by severity of winters, rarely occurring N of areas with mean Jan temperature around or few degrees below 0°C. Prefers open lowlands with some trees, including farmland with hedges, ditches, ponds and banks, roadside verges and related rougher terrain, and young conifer plantations; also around towns, suburbs, villages or more isolated buildings suitable for daytime roosts and nest-sites; sometimes near refuse dumps. In lower latitudes, also semi-arid and some arid regions with xerophytic vegetation, dwarf shrub and herb communities, deciduous or mixed eucalypt woodland, *Acacia* savanna, thornbush, heathland, open marshes, mudflats, oil palm plantations, irrigation areas, rice paddies and cane fields, and cliffs and rocky coasts in some regions, notably on continental offshore islands; some darker island races also in forest; on small tropical islands in all available habitats. Usually lowlands, but at higher altitudes in many areas, up to c. 4000 m.

Food and Feeding. Diet better studied than that of any other raptor, most extensively in Europe and North America but also in Israel, parts of Africa (particularly S Africa) and South America (Galapagos Is, Chile, Argentina, Surinam), Australia, and a few other localities. In major sample studies, 74-100% (in most cases 90-100%) of diet small mammals, usually dominated by only few species, especially rats and mice; in Europe and North America also voles (Cricetidae), gophers (Geomysidae) and shrews (Soricidae); in Africa also shrews, other Insectivora and gerbils (Gerbillinae); in South America also small opossums (Didelphidae); in Australia also bandicoots (Peramelidae), dasyurid marsupials and gliders (Burramyidae/Petauridae). Other mammals include young rabbits and hares (Leporidae), moles (Talpidae), bats, and skunks, stoats and weasels (Mustelidae). Also birds, particularly communally roosting passerines, e.g. thrushes (Turdidae), starlings (Sturnidae), sparrows (Passeridae), weavers (Ploceidae) and finches (Fringillidae), but vast range of other birds in small numbers or of local importance, from seabirds (Procellariidae, Hydrobatidae, Sternidae, Alcidae), small herons (Ardeidae), kestrels (*Falco*), young megapodes (Megapodidae), quails (Phasianidae), domestic fowl, buttonquails (Turnicidae), rails (Rallidae), plovers (Charadriidae), small waders (Scolopacidae), to pigeons (Columbidae), lorikeets (Psittacidae), cuckoos (Cuculidae), swifts (Apodidae), kingfishers (Alcedinidae) and small woodpeckers (e.g. *Colaptes*), and wide range of passerines from at least 12 families. Other prey lacertid and agamid lizards, skinks (Scincidae), geckos (Gekkonidae), chameleons (Chamaeleonidae), slow-worms (*Anguis fragilis*) and grass snakes (*Natrix natrix*); frogs (Anura) and toads (Bufonidae); small fish, e.g. trout (*Salmo*), roach (*Rutilus*), carp (Cyprinidae), rudd (*Scardinius erythrophthalmus*), perch (*Perca*) and grunion (*Leuresthes tenuis*); larger insects, e.g. grasshoppers (Saltatoria), beetles (Coleoptera), mantises (Mantidae), moths (Lepidoptera), wasps (Hymenoptera) and termites (Isoptera); spiders (Arachnida) and scorpions (Scorpionida); littoral isopods (Isopoda); earthworms (Annelida); and rarely carrion. Much non-mammalian prey caught incidentally or opportunistically, but can constitute significant part of diet in some tropical and semi-arid regions, e.g. lizards and invertebrates in parts of Africa and on some islands. Discarded eggshells and faeces of smaller nestlings may also be eaten; occasional chick cannibalism at nest, victim usually dead from unknown causes, but young recorded killed and eaten by siblings. In some temperate regions, when main prey species scarce or absent, many starve rather than switch to alternatives; this also occurs in boom/bust cycle of rat and mouse plagues, when excess production of young leads to many often starving. Hunts close to ground in searching flight, undulating and hovering, diving on to prey with talons extended, usually from height of c. 3 m, also commonly from perch; either method used by same bird, or one more than other, depending on habitat type, e.g. perch-hunting predominant in denser vegetation. Normally strictly nocturnal, with high auditory acuity in locating prey in complete darkness. Daylight hunting regular in Scotland and England and well known on various Pacific islands; also observed elsewhere, e.g. W USA (Utah) and Surinam, though extent unknown; may be widespread if owls

not mobbed when they appear. Normally hunts singly; sometimes many together during prey plagues, e.g. in Australia, where often joined by *T. longimembris*, *T. novaehollandiae* and other raptors.

Breeding. In tropics can start in almost any month, generally late in dry season, in more arid areas during wetter periods; in N temperate regions mostly Mar-Jun, when double-brooded mostly Mar-May and Jun-Aug, initial activity varying among habitats; in some temperate regions season correlated with cycles of prey abundance, but similar from year to year where highly dependent on more homogeneous agricultural landscapes; in South Africa after rains, Feb-May in summer rainfall regions and Aug-Dec in winter rainfall region of SW Cape, but can breed in any month depending on local conditions; in Australia opportunistic according to food supply, can be at any time of year, most peaking Mar-Jun and Aug-Nov; May-Aug in New Caledonia, 1 or 2 broods, rarely 3 (e.g. in Malaysia), depending on food supply; exceptionally, 4 (Zimbabwe) within 11 months during mouse plague, with first egg of next clutch laid while chicks still in nest. Monogamous, but polygamy sometimes recorded, rarely polyandry and incest; territorial, but loosely colonial nesting recorded in USA; sometimes near other owls, e.g. in Scotland 34-40 m from Tawny Owl (*Strix aluco*) and in USA in association with Great Horned Owl (*Bubo virginianus*); in captivity, hybridization recorded between male of present species and a female Striped Owl (*Asio clamator*), 2 of 4 eggs fertile and developing until 15th day. Site a natural cavity in tree trunk, stump or large hollow branch, 2-20 m above ground, or in cliff or bank, including sea-cliffs and small, exposed islands, in cave, walls of lava tubes, even in ground; also in hollow of palm tree; wide diversity of artificial structures with adequate room and access also used (e.g. old church, tower, castle, ruin, barn, abandoned building, loft, dovecote, windmill, disused water tank, arched bridges and other large structures, lighthouse, chimney, haystack, duckblind, unused boat, up to 10 m down in abandoned well); also purpose-built nestboxes and those used in rat-control programmes (e.g. in Malaysia); burrows c. 1 m deep in cliffs and banks may be wholly or partially excavated; also uses large abandoned nest, e.g. of Osprey (*Pandion haliaetus*), in Africa of Hamerkop (*Scopus umbretta*) and communal nests of Sociable Weaver (*Philetairus socius*); sometimes takes over occupied nest, e.g. in Scotland wool-lined stick nest of Eurasian Jackdaw (*Corvus monedula*) in chimney, yet also recorded sharing active site with latter; some sites used over multiple seasons; either no nest or slight scrape or depression, with pellets and other debris as insulating layer. Clutch 2-16 eggs, usually 4-7, laid 2-3 or more days apart; if first clutch lost, replacement usually smaller; incubation 29-34 days; male's only involvement is in feeding female and young; natal down white, second (mesoptile) down white, creamy-white or buffish-cream; nestling period 7-10 weeks; young dependent on parents for further 3-5 weeks, then disperse within 2-8 weeks. Most hatched chicks survive; in South Africa, record of 12 chicks successfully reared from a single nesting attempt. Can breed in less than 1 year.

Movements. Most populations sedentary, with post-breeding dispersal of juveniles, as well as some movement of adults where prey numbers fluctuate. Data from Europe and North America indicate considerable regional variation, particularly after high prey abundance. In Scotland most disperse within 20 km; in C Europe 50-100+ km to W & S, with a few ringing recoveries 1200-1600 km distant; Dutch-ringed young moved c. 1500 km to Spain and Ukraine; nominate race vagrant to Azores, *guttata* to Jan Mayen I, S Scandinavia and S Finland, each also vagrant within other's range. In America, *pratincola* from N USA move generally farther, 80-320 km, with recoveries at up to 1760 km; in S USA most disperse within 80 km, but recoveries at 248 km and 984 km indicate that wide dispersal not entirely due to severe winter weather; wanders or strays seasonally to Newfoundland, S Alaska, Tres Marias and Revillagigedo Is off W Mexico, Cuba, Hispaniola, Puerto Rico, Jamaica and Central America. Reported evidence of migration in NE USA suggested as flocking behaviour associated with post-breeding dispersal. Middle Eastern race *erlangeri* vagrant to NE Iran/Transcaspia region. Movements of Afrotropical *affinis* include 1000 km from Senegambia to Sierra Leone and 579 km and 400 km within S Africa. Indian/Indochinese race *stertens* may be merely vagrant to SC China (Yunnan), though recent sources suggest rare resident there; records from southernmost Thailand since 1970's may be N-moving *javanica* rather than *stertens* (*javanica* formerly only vagrant W of Java, with spread as breeding bird only since 1960's). Movements of 65-840 km recorded for *delicatula* in SE Australia, where some populations highly nomadic, with irruptions associated with rodent plagues, as well as seasonal movements to N areas for dry season (winter) and away from coasts in summer, doubtless accounting for long-distance vagrancy to Norfolk and Lord Howe Is and New Zealand. However, several New Zealand records are of birds transported in undercarriage bays of aircraft (1, dead on arrival, apparently from USA), and some may originate from Fiji; the 7 or 8 records include 1 on Little Barrier I, Jun-Oct 1992. Race *delicatula* also irregular visitor to Tasmania and Bass Strait islands and vagrant to Houtman Abrolhos off W Australia. In S South America *tuidara* has occasionally reached Falkland Is, where breeding first reported 1989; also on South Georgia, where evidence of breeding observed in 1998. Over-water dispersal is obvious source of many vagrants; several records of owls landing on ships up to 360 km from land suggest some vagrancy ship-assisted, e.g. a New Jersey bird recovered in Bermuda (c. 1250 km), where first bred 1931; also sightings on offshore oil rigs. In some tropical areas inter-island movement common, e.g. in smaller island groups of Fiji. Unidentified dark *Tyto* owls recently observed on several Fiji islands, if not vagrant *T. longimembris*, could be dark-morph birds of present species, hitherto unknown from Fiji.

Status and Conservation. Not globally threatened. CITES II. Status of many populations uncertain, particularly those on islands, but others locally common; species expanding in some areas, especially temperate regions, as a result of increases in availability of suitable habitats and artificial nest-sites. Formerly occurred N to S Scandinavia, and small numbers have been reintroduced to S Finland; recently extinct in Malta, where last bred in 1988; has also disappeared from Aldabra; recorded in error from Austral Is and Society Is; recent breeding records in Falkland Is. Current European population 110,000-230,000 breeding pairs, with c. 90% of nominate race and two-thirds of total in just 2 countries (France and Spain); densities of up to c. 25 pairs/50 km² but generally much lower, especially in E Europe. Far greater densities attained in some nestbox programmes, e.g. on oil-palm estates in Malaysia; species first discovered nesting in Peninsular Malaysia in 1969 on an oil-palm estate, where many owls had been attracted to large population of rats feeding on oil palms; few nest-sites were available, but owls responded well when nestboxes provided; in 1988, attempt at biological control of rats, with 200 nestboxes erected for present species in 1000 ha of oil palms near Kuala Lumpur; by late 1989, 95% of boxes occupied, giving density of c. 1 pair/5 ha, and offering alternative to use of second generation rodenticides; species now common throughout Malay Peninsula. Nestboxes used as part of local conservation efforts in Europe and North America, where N populations have been declining for c. 50 years; causes of decline include loss and fragmentation of grassland foraging habitat, intensification of agricultural practices since 1940's, urbanization, and road development, with attendant upsurge in road mortalities, all coupled with increasingly harsh winters during that period. Increased mechanization of farms has meant loss of important foraging sites, such as stackyards and stables, and loss of abandoned farm buildings suitable for nest-sites. Organochlorine pesticides in 1950's and 1960's and rodenticides in 1970's and 1980's had disastrous effects on many owl populations in Europe, particularly NW Europe, and parts of North America; in NE Australia, rodenticides used since 1992 for rat control in cane fields have caused local population declines of 75-85%. Conservation efforts have also included protection and re-establishment of rough-grassland habitat mosaics, providing prey-rich foraging areas, and controls over use of second-generation anticoagulant rodenticides; reintroduction schemes in some areas have had mixed success, as well as conflicting with wild populations. While mortality rates in temperate regions can be very high, birds start breeding in first year, lay large clutches, young grow rapidly, and losses can quickly be replaced, so long as

suitable habitat, prey abundance and nest-sites exist. Most die within 1-2 years, but ringing returns have demonstrated that small numbers survive for up to 21 years.

11. Ashy-faced Owl

Tyto glaucops

French: Effraie d'Hispaniola **German:** Hispaniolaschleiereule **Spanish:** Lechuza de la Española
Other common names: Hispaniolan/Ashy-faced Barn-owl

Taxonomy. *Str[ix] glaucops* Kaup, 1853, Jamaica; error = Hispaniola.

Until recently considered conspecific with *T. alba*. Following colonization of Hispaniola in late 1970's by *T. a. pratincola*, latter found not to interbreed with nominate *glaucops*, and separation as two species now widely accepted. Several recent works consider nominate *glaucops* part of a natural group including *insularis* and *nigrescens* (last 2 forms possibly comprising a separate species, *T. insularis*), with extinct form *T. cavatica* from intervening island of Puerto Rico also considered closely related to this group; others place *insularis* and *nigrescens* in *T. alba*. On present evidence, best option may be to treat the three extant races as one species, with *cavatica* probably representing an extinct race. Limited available data suggest similarities to small island races of *T. alba* that may also warrant treatment as separate species. Colour characters of race *nigrescens* may not be tenable. Three subspecies tentatively recognized.

Subspecies and Distribution.

T. g. glaucops (Kaup, 1853) - Hispaniola, including Tortue I.

T. g. nigrescens (Lawrence, 1878) - Dominica.

T. g. insularis (Pelzelin, 1872) - St Vincent, Bequia, Union, Carriacou and Grenada.

Descriptive notes. 26-43 cm. Nominat race has distinctive silvery-grey facial disc, dark greyish-brown upperparts with light brown and dusky vermiculations, mixed with buff or tawny mottling on wings, and tawny underparts with some transverse barring. Occurs in light and dark morphs, with intermediates. Sexes similar, but female slightly larger. Juvenile has darker grey face. Race *insularis* has vinaceous-brown facial disc, blackish-grey upperparts sparsely spotted or streaked white, darker wings mottled and edged tawny, cinnamon-buff underparts mottled dusky with some small white spots; *nigrescens* like *insularis*, but almost lacks white spotting above and has less mottling below. **VOICE.** A hissing cry, prefaced by a series of higher-pitched ratchety clicks and a screeching call likened to "criiissssh" recorded for Hispaniola. On Dominica, a piercing scream and a loud clicking sound recorded. Other calls may be similar to some calls of *T. alba*. **Habitat.** Open woodland, forest, scrub and caves; also agricultural areas, abandoned buildings, villages and towns; from lowlands to over 2000 m. **Food and Feeding.** Mainly small mammals, including rats, mice and small bats; also birds, including domestic fowl, doves (Columbidae), cuckoos (Cuculidae), swifts (Apodidae), hummingbirds, (Trochilidae), trogons (Trogonidae), todies (Todiidae), woodpeckers (Picidae), swallows (Hirundinidae), thrushes and solitaires (Turdidae), Palmchats (*Dulus dominicus*), weavers (Ploceidae), vireos (Vireonidae), finches (Fringillidae), New World warblers (Parulidae) and tanagers (Thraupidae); anolis lizards (Iguanidae); and tree frogs (Hylidae). Nocturnal hunter, foraging habits similar to those of *T. alba*. **Breeding.** Eggs in Sept on Dominica; nestlings Apr; main season Jan-Jun on Hispaniola. Natural cavity nest-sites, including hollow trees and branches, sinkholes, also cave ledges, and artificial sites similar to those of *T. alba*. Clutch 3-7 eggs; no other data.

Movements. Sedentary; extent of post-breeding dispersal unknown.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Hispaniola EBA. Widespread and locally common on Hispaniola; in Dominican Republic said to be common, particularly in S parts. Status of Lesser Antillean races insufficiently known, but *nigrescens* appears to be common on Dominica, whereas *insularis* is rare on St Vincent and Grenada and in Grenadines.

Bibliography. Anon. (1989c, 1998a), Bond (1928a, 1928c, 1942, 1949, 1956a, 1978, 1979, 1985, 1987), Clark *et al.* (1978), Dod (1987), Hartert (1929), Hill (1964), Lack & Lack (1973), Lack *et al.* (1973), Olson (1978), Raffaele *et al.* (1998), Ridgway (1914), Sharpe (1875, 1876), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wetmore & Swales (1931).

Family TYTONIDAE (BARN-OWLS) SPECIES ACCOUNTS

12. Madagascar Red Owl

Tyto soumagnei

French: Effraie de Soumagne **German:** Malegasseneule **Spanish:** Lechuza Malgache
Other common names: Madagascar Grass-owl/Masked-owl, Soumagne's Owl

Taxonomy. *Heliophilus Soumagnei* Milne-Edwards, 1878, Madagascar.

Close relative of *T. alba* group, of which it constitutes a small, dark, island form. Sufficiently differentiated, however, always to have been regarded as a separate species, and indeed sometimes a separate genus, *Heliophilus*. Monotypic.

Distribution. NE & E Madagascar.

Descriptive notes. 27.5-30 cm; 323 g. Plumage suffused orange-red, darker above and paler below, with fine black spots; facial disc greyish-buff, darker around eyes; eyes blackish. Sexes similar.

Juvenile similar to adult, but initially brighter. **Voice.** Loud, eerie, hissing screech, "shreeee", dropping towards end, similar to that of *T. alba* but higher-pitched and more vigorous; also "wok wok wok" or "wac-wac-wac..." calls, and a single, explosive call or brief resonant alarm.

Habitat. Traditionally linked with undisturbed rainforest at 900-1200 m, but recent studies indicate forest edge, rice paddies and other cultivation important, at least for hunting, and day roosts found in small ravines among bananas and secondary growth. Radio-tagged bird trapped at sea-level, frequented lowland secondary growth and open areas subjected to human disturbance, roosting during day in secondary vegetation. Forages in forest and nearby open areas.

Food and Feeding. Almost exclusively small native mammals (insectivores and rodents), especially shrewlike tenrecs (*Microgale*), rice tenrecs (*Oryzomys*) and tuft-tailed rats (*Eliurus*), in size range 13-72 g; also occasional rats (*Rattus*) and old report of frogs. No information on feeding behaviour; strictly nocturnal, and recorded singly or in pairs.

Breeding. Only 1 nest described: site c. 23 m above ground in natural tree cavity; 2 recently hatched young Sept; natal down white, developing noticeable facial disc at 1 month; fledged Nov-Dec at 10

On following pages: 13. African Grass-owl (*Tyto capensis*); 14. Eastern Grass-owl (*Tyto longimembris*); 15. Oriental Bay-owl (*Phodilus badius*); 16. Congo Bay-owl (*Phodilus prigoginei*).

weeks, and remained in natal area for at least c. 4 months.

Movements. Apparently sedentary; radio-tagged bird was sedentary over 15 months, nesting 2 km from original roosting area of a year earlier.

Status and Conservation. ENDANGERED, CITES I. Restricted-range species: present in East Malagasy Wet Forests EBA. Old records from Sihanaka forest and Masoala Peninsula; sighting in 1973 near Andasibe was first record in wild since 1934; 1 found in captivity in Aug 1993 at Andapa, in Anjanaharibe Sud Special Reserve, c. 300 km N of known range. Individual trapped in Oct 1994 in Masoala Peninsula was radio-tagged and monitored until Dec 1995 using radio telemetry; had home range of 210 ha; in Sept 1995 it nested and raised 2 young, 1 of which was fitted with a transmitter and observed through Mar 1996, 4 months after it had fledged. Probably always uncommon within restricted range, much of which is threatened by habitat destruction; true distribution and status, however, possibly clouded by confusion with *T. alba*, which is widespread and relatively common throughout Madagascar. Intensive research and conservation urgently required.

Bibliography. Allen & Greenway (1935), Anon. 13. African Grass-owl

Tyto capensis

French: Effraie du Cap **German:** Kapgraseule **Spanish:** Lechuza de El Cabo
Other common names: Grass Owl(!), Cape/Common Grass-owl, Cape/African Owl

Taxonomy. *Strix Capensis* A. Smith, 1834, Cape Town, South Africa.

Forms superspecies with *T. longimembris*, and often treated as conspecific. Some minor variation recorded, but races *damarensis*, *libratus* and *cameroonensis* considered no longer tenable. Monotypic. **Distribution.** Cameroon highlands (3 records); Congo and N Angola E to S Uganda and W Kenya, then S through W Tanzania and Zambia to W Mozambique and E South Africa (formerly W to Cape Town); single record from Ethiopia; recorded in error from Namibia.

Descriptive notes. 34-37 cm; 266-520 g. Dark sooty olive-brown upperparts with white dots contrast distinctly with whitish to pale buff underparts with dark spots; facial disc pale buff to whitish; eyes small, dark; bill creamy. Larger and darker than *T. alba*; confusable, particularly in marshy areas, with Marsh Owl (*Asio capensis*), but latter has dark face and underparts, more rounded wings, darker (less white) underwing, is less nocturnal and retracts legs when flushed (present species dangles legs). Sexes alike. Juvenile darker above without white spots, with more rufous facial disc, and darker buff below. **Voice.** Similar to *T. alba*, but less strident, more muted screeches; soft, cricket-like "tik-tik-tik..." given on wing; high-pitched, sibilant tremolo of 1-2 seconds also noted; nestlings utter snake-like hiss.

Habitat. Open grassland, vleis, marshes and lush moist grassland up to 3200 m; also open *Acacia* woodland. By day roosts in nest or separate tunnel structure, in pairs or groups of up to 5 birds; uses same roost regularly, when birds may extend tunnels up to 1-5 m long to connect with other tunnels.

Food and Feeding. Prey includes rodents, especially vlei rats (*Otomys*), also shrews (Soricidae), hedgehogs (Erinaceidae), elephant-shrews (Macroscelididae), young hares (Leporidae), bats, birds up to size of crakes (Rallidae) and snipe (*Gallinago*), reptiles, frogs, dung beetles and termites; weight range of prey 1.5-120 g; also eats eggshells. Pellet studies have shown that rodents comprise 76-98% of diet. Hunts in low, quartering flight, usually starting earlier in evening and finishing later in morning than *T. alba*; at grass fires, hunts rodents escaping from flames.

Breeding. Breeds at time of greatest grass cover: Oct-Jul in South Africa; Nov-May, mainly Feb-Apr, in Zimbabwe; Feb-Jun in Malawi and Zambia; Apr, with nestlings recorded Jan, Mar and Aug, in Zaire; and Aug-Mar in E Africa. Nest usually near or under a bush, a flattened pad of grass at end of grassy tunnel in dense tuft, also connected to other tunnels running through grass which can be used for escape by adults and young (if old enough) if nest invaded by predator. Clutch 2-5 eggs, rarely 4; incubation 32-42 days, eggs hatching within 24-hour period or on consecutive days; natal down white, second (mesopile) down buff or pale golden-brown; young fledge in c. 42 days, but stay near nest for further c. 30 days.

Movements. Sedentary. Some local movements likely, depending on food supply, as well as post-breeding dispersal of juveniles; Ethiopian record perhaps of juvenile. Possible vagrant to W Gambia.

Status and Conservation. Not globally threatened. CITES II. Most numerous in E Africa; sparsely recorded in C Africa; locally common in Zambia, Malawi, Zimbabwe and Mozambique; local and uncommon in South Africa, where numbers declining through habitat destruction. Scarcity in many areas is also attributed to competition with *Asio capensis*, which is commoner (ratio 9:1), although the two species are recorded sharing roost-sites.

14. Eastern Grass-owl

Tyto longimembris

French: Effraie de prairie **German:** Graseule **Spanish:** Lechuza Patilarga
Other common names: Grass Owl(!), Australasian Grass-owl

Taxonomy. *S[trix] Longimembris* Jerdon, 1839, the Nilgiris, near Coonoor, India.

Forms superspecies with *T. capensis*, with which often considered conspecific. Variation within species poorly understood, owing to rarity of specimens from whole range. Several other forms previously separated racially (*walleri*, *oustalei*, *maculosa*) now included in nominate *longimembris*, although Australian *walleri* perhaps warrants recognition due to plumage differences and sexual dimorphism; Guangxi Zhuang and Guangdong population (*melli*) merged with *chinensis*; *chinensis* itself sometimes included in *pithecopis*, but probably better retained as separate race. Six subspecies recognized.

Subspecies and Distribution.

T. l. longimembris (Jerdon, 1839) - India, S Nepal, Bangladesh and Myanmar; Sulawesi, Tukangbesi Is (Kaledupa), Flores, Sumba and N, C & E Australia.

T. l. chinensis Hartert, 1929 - SE China (SE Yunnan to Jiangsu) and Vietnam.

T. l. pithecopis (Swinhoe, 1866) - Taiwan.

T. l. amaurota (Cabanis, 1872) - Philippines.

T. l. baliem Ripley, 1964 - W New Guinea (Baliem Valley, Snow Mts).

T. l. papuensis Hartert, 1929 - E New Guinea (C & SE ranges, Huon Peninsula).

Descriptive notes. Male 32-36 cm, 265-375 g (Australia), 360 g (Philippines); female 35-38 cm, 320-450 g (Australia), 582 g (Philippines). Male dark brown and golden-buff above with some small white spots; facial disc and underparts contrastingly whitish, tinged orange-buff, underparts with sparse blackish dots; flight feathers barred dark, with golden-buff patch at base of primaries; tail pale, barred dark; eyes dark. Darker than sympatric races of *T. alba*; generally not so dark as *T. capensis*. Female as male, or with darker face and underparts. Juvenile resembles adult female, or darker. Australian birds ("walleri") slightly buffier and on

average with more dorsal and ventral spotting, could be confused with light-morph *T. novaehollandiae*; race *chinensis* entirely suffused tawny-buff, but some paler; *pithecopis* larger, with some buff suffusion; *amaurota* like nominate, but slightly larger, upperparts more greyish, buff areas more yellowish, tail bars wider, female and juvenile with facial disc washed vinaceous-brown; *papuensis* upperparts plainer, darker grey with narrow white shaft streaks, not spots (but some nominate also with streaks), size approaching or equalling *pithecopis* and *amaurota*; type (adult male) of *baliem* described as having upperparts much darker than *papuensis* and extending to 2 dark patches on sides of neck, possibly averages smaller. **Voice.** In Asia noted to have screech like *T. alba*, but generally more silent. Various calls recorded in Australia: hissing scream in flight over breeding grounds, with loudness and harshness intermediate between *T. alba* and *T. novaehollandiae*; cricket-like chirruping by male returning to nest with food, audible only at close range, highly sibilant "psseoo" in flight near nest (perhaps alarm call); another possible alarm near nest is harsh "scaarp, scaarp" by female; also bill- or tongue-snapping, and snoring and high-pitched trilling or wheezing calls by nestlings.

Habitat. Grassland, both tall grass jungle and open grassland, paperbark (*Melaleuca*) savanna, marshes, floodplains and heathland, particularly when undisturbed by human activity, but also cultivated and cleared areas, including cane fields; in Australia, recently young pine plantations. In many regions, prefers grassy hillsides with thick cover and mid-mountain grassland to c. 2500 m. In Australia apparently 2 main populations: one coastal in marshy heaths and swampy tussock grassland, other inland on floodplains, frequenting treeless tussock grassland and swampy depressions containing areas of rushes, sedges and lignum (*Muehlenbeckia*), also flooded bore drains. While normally perching only on ground, recent Australian observations included perching on tops of young pine trees.

Food and Feeding. Specialized rodent-hunter; in Australia, also small dasyurid marsupials (*Sminthopsis*, *Plaginale*); rarely, ground birds such as buttonquails (*Turnix*), reptiles, frogs, and large insects such as grasshoppers (Saltatoria), locusts (Acrididae) and cicadas (Cicadidae). Unlike *T. alba*, hunts entirely by low, quartering flight, with glides and hovers, similar to harriers (*Circus*), plunging head-first into grass. As with *T. capensis*, hunting begins earlier than *T. alba* and finishes later; in Australia, this pattern found in situations of stress after inland rodent plagues, when hunting began about 1 hour before dusk and continued to mid-morning. Although rarely seen unless flushed, in NE Australia plagues of e.g. long-haired rats (*Rattus villosissimus*) and cane rats (*R. sordidus*) may result in relatively large concentrations of this species, often mixed with *T. alba*, *T. novaehollandiae* and other raptors. When rat numbers crash, many owls starve.

Breeding. Oct-Mar, mostly Oct-Dec, in India, but once Jul; Sept-Jan in China and Philippines; May-Jun in Papua New Guinea; Feb-Sept in E coastal Australia; at any time of year depending on conditions in inland Australia. Usually solitary, but in favourable conditions sometimes loosely colonial, with nests separated by few hundred metres. Nest on ground in dense grass usually over 1 m high, or in sedges, usually away from trees, but in Australia once below mangrove and recently in young pine plantation; flimsy pad or mat of grasses soon trampled by nesting activity, canopied in grass and with series of (usually 3) approach tunnels or pathways, even over shallow water, made by pushing through to nest; entrance to main tunnel flattened by frequent food deliveries. Clutch 4-6 eggs in India, 3-8 in Australia, more pearl-shaped than in other *Tyto*, usually laid at 2-day intervals; incubation 31 days in Australia; natal down white, second (mesopile) down whitish in Philippines, buffy in China, tawny to buff or golden-brown in Australia; young fledge after c. 2 months, hiding in grass during day and returning to nest at night, and may stay around nesting area for some weeks, at least in Australia.

Movements. Generally sedentary throughout much of range, with some post-breeding dispersal of juveniles. Earlier reports of migration in China and Philippines subsequently attributed to winter breeding activities in former country and occasional flocking in latter. Records of vagrancy within Australia explained by general nomadism and dispersal of inland birds when favourable breeding conditions terminate, but such movements may also involve some coastal birds, particularly juveniles; N Australian populations possibly not permanent, but result of population explosions in interior; vagrancy elsewhere in Australia probably represents post-breeding dispersal of juveniles, usually coastward, including offshore islands, with nominate race recorded in SE & SW Australia, Palm Is and Magnetic I off Queensland, and Torres Strait islands. The few records from Indonesia, New Caledonia and Fiji (Viti Levu) may be of inland Australian birds, which are more likely to wander such distances; although it has been suggested that records from some of these islands indicate resident or former resident populations, it is not known if breeding has occurred on any of them. In E New Guinea normally found above 2500 m, but sometimes down to c. 400 m, and record of 2 birds from SE lowlands may represent vagrancy of nominate race from N Australia. Recent

observations of dark *Tyto* owls on several Fijian islands may have included present species, but unconfirmed, and probably *T. alba* although no dark morph of latter known there. Recorded (*chinensis*) as possible vagrant to Hong Kong, but probably captive escapes; also, May 1975 record from Iriomote, S Ryukyu Is, Japan, said to be *pithecopus* but could be *amaurona* (specimen lost). **Status and Conservation.** Not globally threatened. CITES II. Rare to very rare throughout most of range, but can be locally common in undisturbed areas or during rodent plagues (Australia). Strongholds appear to be India, Australia and New Guinea. In Indian subcontinent, described as rare and local or very local, and no recent records from Bangladesh. Much of apparent rarity possibly due to lack of observations or confusion with *T. alba*, but population declines caused by hunting and habitat loss likely, e.g. in China, Taiwan, Philippines and parts of coastal Australia. In NE Australia, rodenticides used since 1992 for rat control in cane fields have caused local population declines of 75-85%. Patchy distribution indicates possible recent fragmentation, e.g. nominate race and *chinensis* may have had continuous distribution in S Asia but now separated; it has been suggested that they may intergrade W of Vietnam, and also that nominate form probably occurred in Thailand until recently, but no suitable habitat remains there. Also, sufficient similarity between Indian and Australian birds has led to suggestion that the species would be found in Malaysia and W Indonesia, but no known records yet.

Subfamily PHODILINAE

Genus *PHODILUS* I. Geoffroy Saint-Hilaire, 1830

15. Oriental Bay-owl

Phodilus badius

French: Phodile calong **German:** Maskeneule **Spanish:** Lechuza Cornuda
Other common names: Bay Owl, Asian Bay-owl; Sikkim Bay-owl (*saturatus*); Peninsular Bay-owl (*ripleyi*); Ceylon Bay-owl (*assimilis*)

Taxonomy. *Strix badia* Horsfield, 1821, Java. Relationships uncertain. Although has occasionally been considered to include *P. prigoginei* as a race, latter seems to exhibit much too marked differences. Taxonomic status of SE Asian forms requires clarification: birds of Thailand sometimes assigned to *saturatus* and sometimes to nominate *badius*, with those of Myanmar considered intermediate; present arrangement, with populations from N & C Myanmar E to Vietnam and China placed with Indian birds in *saturatus*, and those of S Myanmar and peninsular Thailand in nominate race, perhaps tentative, and extent of possible intergradation between the two in C? & S Myanmar and SW Thailand undetermined. Races *ripleyi* and *arixuthus* might be untenable, as based on unique types. Also, single record from E Philippines (Samar) described as separate race, *riverae*; included in nominate race in recent works, though size and colour characters in type description suggest closer affinities to *saturatus*, or possibly a valid race, but specimen destroyed in 1945 and no further conclusions possible. Six subspecies tentatively recognized.

Subspecies and Distribution.

P. b. saturatus Robinson, 1927 - Sikkim and NE India, N & C Myanmar and Thailand (except peninsular) E to Vietnam and SE China (S Yunnan, SW Guangxi Zhuang, Hainan I); presence in Nepal, Bhutan and Bangladesh unconfirmed.
P. b. ripleyi Hussain & Reza Khan, 1978 - Anaimalai-Nelliampathy Hills (SW India).
P. b. assimilis Hume, 1877 - C & S Sri Lanka.
P. b. badius (Horsfield, 1821) - Malay Peninsula and Greater Sundas (including Nias).
P. b. arixuthus Oberholser, 1932 - Natuna Is (Bungaran).
P. b. parvus Chasen, 1937 - Belitung I.

nominate but generally paler, with larger white spots above; *parvus* like nominate but smaller, with shorter bill and smaller feet; form '*riverae*' said to have chestnut, boldly streaked upperparts. Voice. Wide variety of calls. In breeding season, once described as surpassing all other owls in appalling nature of its cries, even sounding like half a dozen cats fighting; a single soft hoot; loud 3-note whistle

Descriptive notes. 23-33 cm; 255-308 g. Small, dainty owl with short ear-tufts projecting above sides of head. Chestnut-bay above, spotted with gold, wings barred black; facial disc rather square-shaped, pale greyish-pink; underparts light pinkish-buff, spotted black; eyes very large, blackish. Sexes alike. Juvenile presumably like adult. Races based mostly on variability of brown upperparts, black markings, barring on primaries and size: *assimilis* with dark brown speckled upperparts; *ripleyi* slightly larger, with chocolate-brown, finely stippled upperparts; *saturatus* larger than both, with chestnut, sparsely stippled upperparts; *arixuthus* like

like person calling dog, birds answering each other in forest; also described as a long, musical sequence, opening phrase of 3 notes, second higher than others, succeeded by 3 or 4 rising, quavering phrases, each beginning at successively lower point on scale, "hu-hli-hu, hu-u-u, hu-u-u..."; soft hoot and ringing "hooh-weeyoo"; different type of call depicted as "kwankwit-kwankwit-kek-kek-kek", given in flight in darkness; in captivity, also piercing wail and harsh scream, as well as chuckling sound when food offered, and loud whip-crack sound when frightened.

Habitat. Evergreen and mixed deciduous forest, landward edge of mangrove, partially cleared land and plantations, rarely straying outside these areas. Up to 2200 m; in NE India, foothills to 1500 m; in Sri Lanka, wet lowlands and lower hills. Day roost in hollow tree.

Food and Feeding. Small mammals, birds, lizards, snakes, frogs and large insects, particularly beetles; among avian prey, preference for flowerpeckers (*Dicaeum*) noted in Borneo. Hunts from perch, using rhythmic rocking of head to focus gaze, and captures prey in flight. Strictly nocturnal and usually hunts under forest canopy, where short, rounded wings well suited for rapid flight amid maze of small, vertical stems; with lack of horizontal branches, perches sideways on vertical saplings, behavioural trait once considered unique among owls but recorded also for *Tyto tenebriosa* and *T. multipunctata*.

Breeding. Nov in Sri Lanka, Mar-May in India; eggs laid Oct-Dec in Borneo. Nest an unlined hollow in tree trunk or rotten stump, c. 2-5 m up; same site used over many years, becoming heavily littered with pellets and other debris; one pair laid in nestbox in oil-palm plantation. Clutch 3-5 eggs; incubation and other details undescribed.

Movements. Presumably sedentary, with evidence of some movement, probably post-breeding dispersal of juveniles. Records of nominate race on Penang and Singapore, where species does not breed, indicate some over-sea dispersal; single record in E Philippines, on Samar in 1924, if not part of undiscovered (now extinct) breeding population, would represent surprisingly long-distance vagrancy.

Status and Conservation. Not globally threatened. CITES II. Considered very rare throughout range, though thought to be relatively common in S Malaysia, especially in lowland forest. No Bali record since 1911; extinct in Singapore since 1920's; single record from Nepal in 1846 of doubtful provenance; race *ripleyi* first discovered in SW India in Apr 1976, with only 3 subsequent records. Habits suggest that it can be easily overlooked; on other hand, is nearly helpless if found roosting in daylight, as observed with rediscovery of *ripleyi* in 1992. However, while perhaps genuinely rare in various parts of range, observations suggest adaptability to disturbed forest and other areas affected by human activity, and nesting sites have been found near buildings.

Bibliography. Abdulali (1972), Ali (1962, 1996), Ali & Ripley (1981), Ali *et al.* (1996), Baker (1934a), van Balen (1991), Beddard (1890), Chasen (1937), Cheng Tsohsin (1987), Clark *et al.* (1978), Deignan (1945, 1963), Delacour (1951), Dickinson *et al.* (1991), Etchecopar & Hue (1978), Gibson-Hill (1949, 1950a), Grimmett *et al.* (1998), Hachisuka (1934), Hellebrekers & Hoogerwerf (1967), Henry (1998), Holmes (1996), Hoogerwerf (1949a), Hussain & Reza Khan (1978), Kannan (1993b), Kuroda (1936), Lekagul & Round (1991), MacKinnon & Phillips (1993), van Marle & Voous (1988), Marshall (1966), McGregor (1927), Medway & Wells (1976), Miller (1965), Mudappa (1998), Oberholser (1932), Phillips (1978), Pyrcraft (1903), Riley (1938), Ripley (1982), Robinson (1927), Sharpe (1875), Smythies (1957, 1981, 1986), Sody (1989), Stresemann (1913), Stresemann & Stresemann (1966), Vo Quy & Nguyen Cu (1995), Wang Sung (1998), Wells (1999), Whistler (1944), Zhao Zhengjie (1995).

16. Congo Bay-owl

Phodilus prigoginei

French: Phodile de Prigogine **German:** Kongomaskeneule **Spanish:** Lechuza del Congo
Other common names: African/Prigogine's/Tanzanian Bay-owl, Congo/Itombwe Owl

Taxonomy. *Phodilus Prigoginei* Schouteden, 1952, Muusi, 2432 m, Itombwe Mountains, Zaire. Occasionally treated as race of *P. badius*, but this seems hardly probable, and the two do not appear closely related; inclusion in *Phodilus* perhaps questionable; present species shows some similarities to *P. badius* in plumage coloration, but shape of facial disc rather different, more heart-shaped, as in *Tyto*. Monotypic.

Distribution. Itombwe (Mitumba) Massif, extreme E Zaire; also probably adjacent SW Rwanda (Nyungwe forest) and NW Burundi (near Teza).

Descriptive notes. Female c. 23-29 cm, 195 g. Male undescribed, presumably similar to female. Female deep rufous-brown above, feather tips with small black-edged white spots, wings and tail barred dark brown; facial disc light rufous-buff, with darker rim; pale rufous below, breast and flanks finely spotted dark brown; eyes relatively small, dark brown to blackish. Differs from *P. badius* in heart-shaped (not squarish) facial disc, lack of ear-tufts, more compressed bill and relatively small feet with robust claws. Juvenile unknown. Voice. Unconfirmed but probable Rwanda record based on call, described as "wok wok wok", considered structurally similar to that of *P. badius*.

Habitat. Both definite records from montane forest interspersed with bamboo thicket and grassland, at 1830 m and 2430 m; 1 bird discovered roosting in a grass clearing, subsequently recorded flying 50 m inside gallery montane forest (wooded valleys and scrubby open tops). Two probable records from similar habitats, at 2000 m and 2500 m. Presumably depends on forest, including selectively logged forest and edge; probable Burundi sighting, in forest surrounding tea estate, suggests possible use of hunting territory outside forest.

Food and Feeding. Undescribed.

Breeding. Undescribed.

Movements. Presumably sedentary.

Status and Conservation. **VULNERABLE.** CITES II. Restricted-range species; present in Albertine Rift Mountains EBA. Rare and elusive. Many unsuccessful attempts to find the species since its initial discovery in Mar 1951, until rediscovered (mist-netted and released unharmed) in same region in May 1996. The two unconfirmed records are very close to species' only known locality, the nearest being c. 50 km to E, where probably heard in Jan-Feb 1990; Burundi observation, however, was as long ago as Dec 1974. Further research clearly required.

Bibliography. Anon. (1996a), Brown (1970), Browne & Browne (1999), Butynski *et al.* (1997), Chapin (1954), Clark *et al.* (1978), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dowsett (1990), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Hall & Moreau (1962), Kemp & Kemp (1998), Lippens & Wille (1976), Prigogine (1971, 1973, 1980), Sayers (1986), Schouteden (1952, 1954a), Shuker (1993), Snow (1978), Stattersfield *et al.* (1998), Voous (1966), White (1965).

Class AVES
Order STRIGIFORMES
Family STRIGIDAE (TYPICAL OWLS)

- Large-headed nocturnal birds with strong, hooked bill, round facial disc, compact body, moderately short tail, and strong feet with sharp talons; plumage soft and cryptically coloured.
- 12-75 cm.

- Cosmopolitan.
- Virtually all terrestrial habitats, from Arctic to tropics; typically found from sea-level to c. 2000 m, but locally up to 4700 m.
- 25 genera, 189 species, 548 taxa.
- 21 species threatened; probably 1 of these, as well as 4 other species and 2 subspecies, extinct since 1600.

Systematics

With some 189 living species, Strigidae is by far the larger of the two families that form the order Strigiformes. Ranging in size from the diminutive Elf Owl (*Micrathene whitneyi*) at 40 g to the immense Eurasian Eagle-owl (*Bubo bubo*) at 4 kg or more, the typical owls nonetheless comprise a distinct and easily recognized group of predatory birds. Within the family, however, similarities in plumage and morphology, coupled with a basic lack of information on the behaviour of many species, have led to considerable confusion regarding species and even generic limits. Indeed, the internal taxonomy of the Strigidae may be in a greater state of turmoil than is that of any other family of non-passerine birds. The problem is especially acute in *Otus* (scops-owls and screech-owls) and *Glaucidium* (pygmy-owls and owlets) that inhabit tropical forest, in which fieldwork is notoriously difficult. Recent studies based largely on analyses of vocalizations have revealed that the numbers of species within these genera have been greatly underestimated. Without question, many species remain to be described: some that await discovery in the wild, and others that have been misclassified because nothing is known of their biology. Truly, these are exciting times for the owl taxonomist.

Owls are well represented in the fossil record. As paleontologist S. L. Olson has pointed out, however, our understanding of their evolutionary history is incomplete, owing to the lack of a comprehensive revision of the fossil taxa. The oldest fossils attributed to owls were fragments of leg bones discovered in Upper Cretaceous deposits in Romania. Described as two species in a new fossil family Bradynemidae, these fossils were in fact from small dinosaurs. The oldest known fossil that unquestionably is an owl, *Ogygopteryx wetmorei*, was discovered in Colorado, USA, in Paleocene deposits that are about 58 million years old. The description of this form was based on a nearly complete tarsometatarsus, and the species was placed in the extinct family Ogygopterygidae.

Owls are believed to have undergone a major radiation in the Eocene or late Paleocene, more than 50 million years ago. Three extinct families of owls have been described from middle and late Eocene deposits in western North America and from late Eocene to early Oligocene deposits in the Phosphorites du Quercy, France. The Quercy fossils also show that the family Tytonidae, which includes the modern barn-owls, was highly diversified in Europe during the Eocene (see page 34). The ex-

act timing of the appearance of the family Strigidae is uncertain. Seven species from Quercy that were originally placed in the Strigidae (including a "*Bubo*" and an "*Asio*") actually belong to the Tytonidae. *Bubo poirrieri* from the Lower Miocene of France approximately 24 to 22 million years ago, and *Strix brevis* from the Lower Miocene of western North America, are among the earliest fossils reliably attributed to the Strigidae. Thus, it appears that the Tytonidae preceded the Strigidae during the evolutionary history of owls, and that Strigidae is of Neogene origin.

Some of the relatively recent fossil owls are especially interesting, because their remains suggest that they were vastly different from the owls of today. For instance, *Ornimegalonyx oteroi* from the Pleistocene of Cuba was absolutely gigantic: its height exceeded 1 m, its tarsus was twice as long as that of the Eurasian Eagle-owl, and it had the most powerful claws of any known owl. *Ornimegalonyx* was closely related to *Strix*. As stated by O. Arredondo, who described this giant in 1976, "*Ornimegalonyx* had to have been the scourge and terror of most of the larger mammals of the Pleistocene of Cuba."

Also deserving of mention is a distinctive group of owls that was endemic to the Hawaiian Islands. In 1991, S. L. Olson and H. F. James described four species in the genus *Grallistrix* (literally, "stilt owl" in reference to the long legs), one each from the islands of Kauai, Oahu, Molokai and Maui. Of Holocene origin and derived from *Strix*, these owls, along with dozens of other species of extinct birds, would perhaps be alive today were it not for the colonization of the Hawaiian Archipelago by humans approximately 1600 years ago. The long legs and shortened wings of *Grallistrix* were probably adaptations for catching birds, and in this manner *Grallistrix* would have been convergent with the bird-eating hawks of the genus *Accipiter*. That species of *Grallistrix* specialized on avian prey is not unduly speculative. Fossil owl pellets discovered by Olson and James contained the remains of various species of passerines; also, the terrestrial vertebrate fauna of Hawaii prior to the arrival of humans was devoid of rodents and other small mammals.

The order Strigiformes comprises a well-defined group of predatory birds with a strong, hooked bill; a cere at the base of the bill; and sharp, strongly hooked talons. These features are also characteristic of the diurnal birds of prey. In 1758, this convergence in trophic appendages led Linnaeus to place the hawks and owls in the same group, the Accipitres, a practice that was followed, albeit with various name changes, by nearly every avian

Subdivision of the
Strigidae

& Ian Lewington]

taxonomist for the next 130 years. Around 1890, M. Fürbringer and H. von Gadow, among others, noted that owls shared many characters with the nightjars and concluded that the closest relatives of the owls would be found within the suborder Caprimulgi. From that time onwards, the notion that owls were related to nightjars gained nearly universal acceptance, with one notable exception. In 1981, J. Cracraft revived the idea that owls and falconiforms were closely related, this being based on what he perceived to be shared derived characters of the pelvis and the tarsometatarsus. This non-conformist view has not been well received by other ornithologists, most of whom would place the nocturnal and diurnal birds of prey in separate orders.

On the basis of DNA-DNA hybridization data, C. G. Sibley and J. E. Ahlquist placed owls and nightjars in separate suborders within the Strigiformes. Sibley and Ahlquist's data clearly indicate that owls and hawks are not closely related and suggest that turacos (Musophagidae) are the closest living relatives of owls and nightjars. Analysis of mitochondrial DNA by N. Kuroda and associates also supports a relationship between owls and nightjars. The genetic evidence for a close relationship between owls and nightjars is perfectly acceptable, but it seems more appropriate in the present work to follow traditional usage in recognizing the nightjars to be placed in their own order, Caprimulgiformes, juxtaposed to Strigiformes, which thus contains only the very closely related families Tytonidae and Strigidae. Despite the obvious links between these two families, certain well-marked differences clearly support their segregation into two families (see Morphological Aspects).

As for the internal organization of Strigidae itself, J. L. Peters used characters of the external ear and facial disc to divide it into the subfamilies Buboninae, containing 21 genera, and Striginae, with six genera. Bubonine owls have relatively small external ears, no ear flaps, and a facial disc that is more extensive below the eyes than above. In contrast, strigine owls have large ear openings with fleshy flaps, a ligamentous bridge across the opening, and a well-developed facial disc that is just as extensive above the eyes as below. L. H. Kelso and K. H. Voous questioned whether characters of the external ear were taxonomically useful, given their findings that ear size and shape were not completely diagnostic for the two subfamilies. In addition, N. L. Ford pointed out that generic limits in the typical owls were based solely on external morphology such as bill shape and characters of the nostril and cere. Ford's comparative analysis of osteology among owls led to a very different classification from that of Peters.

Ford discovered that the postcranial bones of the strigids gave little clue as to relationships at the subfamily level. The characters of the skull were informative, however, and Ford concluded that the family Strigidae consisted of three distinct groups, which he proposed as the subfamilies: Striginae, containing three tribes and 13 genera; Surniinae, with three tribes and eight genera; and Asioninae, consisting of just two genera. Ford's classification has not been widely adopted by ornithologists, in part because of the highly divergent classifications proposed for owls, and perhaps because it was never published in the open literature. However, the recent work of Olson and James is in general agreement

Placed together in the order Strigiformes, the "true owls" of the family Strigidae and the barn-owls in the Tytonidae are clearly closely related. Both groups are characterized by a strong, hooked bill with a cere at the base, and strongly hooked, sharp talons. Strigid owls differ most obviously from tytonids, however, in having a rounded facial disc rather than the classic heart-shaped disc of the barn-owls. Further differences include the more rounded skull with relatively larger orbits, a furcula that is not fused to the sternum, and a naked uropygial gland, while the strigid sternum has four notches rather than two.

BBC Natural History Unit]

with Ford's conclusions, and most of Ford's classification has been adopted here. Incorporating recent changes in thinking on generic limits, altogether 25 genera of strigids are recognized, arranged into the three subfamilies.

Little can be said about subfamilies in the Strigidae based on DNA-DNA hybridization because Sibley and Ahlquist lacked DNA samples for most of the genera. A study of allozyme divergence in six species of owls, namely the Eurasian Scops-owl (*Otus scops*), Eurasian Eagle-owl, Tawny Owl (*Strix aluco*), Little Owl (*Athene noctua*), Northern Long-eared Owl (*Asio otus*) and Short-eared Owl (*Asio flammeus*), was undertaken by E. Randi and associates; the results suggested that *Athene* was ancestral to modern Strigidae. More recently, M. Wink and P. Heidrich examined nucleotide sequences in the cytochrome-*b* gene of 13 genera of Strigidae. By and large, their results corroborated many of Ford's conclusions that were based on cranial osteology. A clearer understanding of the phylogenetic placement of taxa within the Strigidae will not be possible until genetic analyses are conducted on a larger sample of genera and species.

The tribe Otini contains the widespread genus *Otus*, the monotypic *Pyrroglau*x and *Gymnoglaux*, the two African *Ptilopsis*, and the Philippine *Mimizuku*. *Otus*, comprising the scops-owls and screech-owls, is by far the most diverse owl genus in terms of species, with some 63 inhabiting all continents except Antarctica and Australasia, although it just creeps into the latter off northern New Guinea, where the Biak Scops-owl (*Otus beccarii*) is found. Most of the species occur in Asia, including the islands of Indonesia, and in the New World tropics. The typical Old World scops-owls, placed in the subgenus *Otus* by J. T. Marshall and B. F. King, tend to have short, simple songs. In contrast, the New World screech-owls in the subgenus *Megascops* have long, complex songs that often contain fast trills. On the basis of its slow, simple song, the Flammulated Owl (*Otus flammeolus*) of the pine forests of western North America is placed with the scops-owls, being the only New World member of that subgenus.

Most members of the tribe Otini are small to medium-sized and have short legs, conspicuous ear-tufts, and cryptic plumage with much streaking and barring. An exception to this general pattern is the Cuban Screech-owl (*Gymnoglaux lawrencii*), which has no ear-tufts and has long legs resembling those of the Bur-

rowing Owl (*Athene cunicularia*); another is the Palau Owl (*Pyrroglau*x *podarginus*), which is also virtually tuftless, has relatively long legs, and has black-and-white tail-coverts and a white carpal patch, in marked contrast to other members of the tribe. Both of these species are sometimes placed in *Otus*, and both occur on islands where no other species of Otini exist, suggest-

One of a number of monotypic genera in the Strigidae is *Uroglau*x, the Papuan Hawk-owl. This is thought to be closely related to the hawk-owls of the genus *Ninox*, and is sometimes included with the latter. It is strikingly similar to some *Ninox*, in particular the Rufous Owl (*Ninox rufa*), in having strongly barred upperparts and tail, but it differs from that species in having streaked, rather than barred, underparts.

[*Uroglau*x *dimorpha*, Goldie River, Papua New Guinea.

Ardea]

Another monotypic genus contains the Crested Owl, a very strange-looking owl restricted to forest areas from south-east Mexico to Brazil. In terms of its external appearance, this species would seem to have no really close relatives. It bears a superficial resemblance to *Jubula*, and the two genera have sometimes been merged, but the similarities between the two may be due simply to convergence. Some studies have claimed to show both to be linked with *Otus* and with *Bubo*, and an apparent similarity to *Otus* in cranial characters was demonstrated in one case.

More recent work has indicated a possible connection between *Lophotrix* and *Pulsatrix*, based on similarities in postcranial skeleton and in the juvenile plumages of the two. It seems that only further research will reveal the true affinities of the intriguing and little-known Crested Owl.

Four Strix owls inhabiting humid forest in the Neotropics, including the aptly named Black-and-white Owl, were formerly placed in the genus *Ciccaba*, it being considered that they differed from other Strix species in the size of their external ears and their dermal flaps. On the other side of the Atlantic, a single species, the African Wood-owl (*Strix woodfordii*), appeared to show the same structure and was therefore also placed in *Ciccaba*. Later work, however, has revealed no osteological difference between the two groups, which are now merged, this treatment being supported also by DNA studies.

[*Strix nigrolineata*, Costa Rica.

ing that their morphological adaptations were reinforced in an environment devoid of close competitors.

Similarities in appearance have made classification of some species of *Otus* difficult. For example, the Western (*Otus kennicottii*) and Eastern Screech-owls (*Otus asio*), with largely non-overlapping ranges encompassing most of the USA, were classified as a single species until 1983, when the significance of subtle differences in their plumages and vast differences in their vocalizations, in conjunction with new perceptions in species concepts, led to their classification as allospecies within a superspecies complex. Going in the other direction, an undescribed taxon from the arid woodland of north-western Peru was thought to be a new species until N. K. Johnson and R. E. Jones conducted an in-depth analysis of its vocalizations. Despite significant differences in size, the new taxon proved to be more appropriately treated as a subspecies of the Peruvian Screech-owl (*Otus roboratus*) and was described as *O. r. pacificus*.

Species limits in *Otus* are especially sticky in Asia, where the presence of many distinct and little-known populations has yielded several taxonomic nightmares. The "Collared" scops-owl group is a case in point. In 1940, Peters listed 18 subspecies of *Otus bakkamoena* that ranged from India and Pakistan to South-east Asia, Japan and the Philippines. By 1978, J. T. Marshall recognized 13 subspecies of *O. bakkamoena* and considered one, the Mentawai Scops-owl (*Otus mentawi*), to be a full species. Subsequent work has led to the elevation of four more of Peters's races to full species status, so that his original single species now comprises the Mentawai, Indian (*Otus bakkamoena*), Collared (*Otus lettia*), Sunda (*Otus lempiji*), Japanese (*Otus semitorques*) and Palawan Scops-owls (*Otus fuliginosus*). A score or so of subspecies are divided among these six species. Furthermore, at the south-east edge of the range occupied by this group a seventh owl is found, the Philippine Scops-owl (*Otus megalotis*); although more often considered a full species, this, too, has sometimes been included within *Otus bakkamoena*. All seven species would seem best regarded as forming a superspecies.

Otus has also been a challenging group in South America, where a series of expeditions to remote cloudforest habitats has yielded several new species. In 1981, J. S. Weske and J. W. Terborgh described the Cloudforest Screech-owl (*Otus marshalli*) from the Andes of central Peru, and five years later, in 1986, J.

W. Fitzpatrick and J. P. O'Neill described the Cinnamon Screech-owl (*Otus petersoni*) from the Andes of northern Peru and southern Ecuador. In addition, Fitzpatrick and O'Neill proposed that the Colombian Screech-owl (*Otus colombianus*) of cloudforest on the west slope of the northern Andes was also specifically distinct, being closely related to the Rufescent Screech-owl (*Otus ingens*) of the eastern slope. All four species belong to a group of dark-eyed, as opposed to yellow-eyed, Neotropical screech-owls that also includes the amber-eyed Tawny-bellied Screech-owl (*Otus watsonii*) from lowland forest in the Guianas and Amazonia. The Cinnamon and Colombian Screech-owls are extremely similar in the colour and pattern of their plumage but differ in gross measurements, the Colombian being decidedly larger, and in their tarsi, which are large and nearly naked in the Colombian and smaller and partly feathered in the Cinnamon. Also, their voices differ notably, and it is in this respect that it is clear that the Colombian really belongs very close to the Rufescent Screech-owl; indeed, the two are nowadays often considered conspecific. It has been suggested that the Cinnamon Screech-owl may be conspecific with the Cloudforest Screech-owl, but the data available at present seem decidedly scant for such a conclusion. Further complications have emerged with these forms in the proposal that the Cinnamon Screech-owl might be conspecific with the type of "*Otus huberi*". Although this suggestion could be right, the type specimen of "*huberi*", collected more than a century ago, is in very poor condition and, having been mounted at one stage, it is difficult to ascertain the true extent of feathering on the tarsus. Given the circumstances, it would seem that there is little to be gained by resurrecting a long-forgotten name based on a damaged type specimen. A final uncertainty worth mentioning within this group refers to the southern race *usta* of the Tawny-bellied Screech-owl: this form may constitute a further full species, but at present the available data seem insufficient to justify such a split.

In 1966, a scops-owl collected on Great Nicobar Island in the Indian Ocean was erroneously considered a subspecies of the Oriental Scops-owl (*Otus sunia*). A second specimen was obtained in 1977, after which time Marshall treated it as an unnamed taxon of the Moluccan Scops-owl (*Otus magicus*). Two decades later, a re-examination of these specimens led P. C. Rasmussen, in 1998, to describe a new species, the Nicobar Scops-

Some modern taxonomists prefer to "lump" the Asian fish-owls with the eagle-owls in the genus *Bubo*. While the two groups are without doubt closely related, both morphologically and genetically, and also share certain vocal characteristics, there are decided differences between them. The fish-owls, the Buffy Fish-owl being a good example, have a far less pronounced facial disc and, importantly, have unfeathered tarsi and toes and have spiny scales on the soles of their feet. Whether these differences, which are related to the aquatic feeding ecology of the fish-owls, are sufficient for them to be separated generically, however, is a matter of dispute.

owl (*Otus alius*). The species is of uncertain taxonomic affinity but is morphologically closest to the highly variable superspecies complex that includes the Sulawesi Scops-owl (*Otus manadensis*). It has been suggested that it might form a superspecies with two owls from nearby Sumatran islands, the Simeulue (*Otus umbra*) and Enggano Scops-owls (*Otus enganensis*).

Two other newly described species from the Old World are the Sangihe Scops-owl (*Otus collari*) from Sangihe Island, north-east of Sulawesi, and the Moheli Scops-owl (*Otus moheliensis*) from the island of that name in the Comoros. In addition, Madagascar Scops-owls (*Otus rutilus*) from the humid eastern slopes of the island sing a series of 5-15 clear hoots, whereas those from the more arid west give a slower series of 3-7 notes that are less pure than those of the eastern birds. The two forms also differ subtly in morphology, and they probably represent different species. Again, the form of scops-owl from the Comoran island of Mayotte (Maore), currently classified as *O. rutilus mayottensis*, may be another that merits full species status, because it appears to differ vocally, as well as in size and perhaps some plumage characters. Other forms possibly awaiting discovery include one species from the Mascarene island of Reunion, and it has been claimed that the island of Sumba, in the Lesser Sundas, may harbour its own species of *Otus*, although, somewhat surprisingly, some sources put the reports down to misidentifications of the relatively large endemic Sumba Boobook (*Ninox rudolfi*)! Several of the forms in Indonesia currently listed as races seem likely to be promoted to full species over the coming years, particularly some that are currently attributed to the Moluccan and Sulawesi Scops-owls. Prime of these must be the form *sulaensis* of the Sula Islands, already proposed as a species by some authorities, and with a highly distinctive voice. Other firm candidates include *mendeni* of the Banggai Islands, *kalidupae* from the Tukangbesi Islands, and *siaoensis* of the island of Siau, between northern Sulawesi and Sangihe; admittedly, most of these forms remain known only from a handful of specimens, so much work remains in order to establish their status in terms of both taxonomy and conservation. Over the next few years it seems quite likely that the situation in the Comoros will thus progress to a remarkable four species being recognized within this very small archipelago. Even more spectacular, however, could be

the number of species that end up being recognized for the Sulawesi region.

Our understanding of species limits in *Otus* has progressed rapidly during the past 25 years, as witnessed by the fact that, in 1973, J. A. Burton recognized only about half the number of species that are accepted today. Despite this progress, however, it is clear that much remains to be learned. Given the complex nature of variation among the insular scops-owls from Indonesia and the cloudforest screech-owls of the Andes, future studies based on analyses of nucleotide sequences and vocalizations will undoubtedly expand considerably the number of species in this difficult group.

Still within the Otini, the white-faced owls inhabit scrubland and savanna throughout sub-Saharan Africa. The Northern White-faced Owl (*Ptilopsis leucotis*) gives a slow song not unlike that of an Old World scops-owl, whereas the Southern White-faced Owl (*Ptilopsis granti*) has a rapid song that has been compared to that of the Tropical Screech-owl (*Otus choliba*) from South America. Until quite recently, the two white-faced owls were considered to be conspecific and, moreover, were placed in the genus *Otus*. Analysis of the cytochrome-*b* gene, however, indicated that two species were involved, which makes perfect sense given the differences in their vocalizations. Furthermore, and surprisingly, this analysis also suggested that *Ptilopsis* is a sister taxon to the genus *Asio*. Although this potential relationship is recognized, for the present purposes *Ptilopsis* is retained within the subfamily Striginae.

The phylogenetic placement of the Giant Scops-owl (*Mimizuku gurneyi*), which is endemic to the Philippines, has been in question until recently. Attaining a length of 30 cm, *Mimizuku* has been considered an oversized scops-owl by some authorities and a stunted eagle-owl by others. Its song is described as a loud, single note that is unlike those of scops-owls or eagle-owls. Analysis of mitochondrial DNA by H. C. Miranda and associates has shown that *Mimizuku* is closely allied to *Otus* rather than to *Bubo*. The genetic similarities between *Mimizuku* and *Otus* are supported by similarities in cranial morphology, but differences between the two taxa in size, plumage and vocalizations suggest that phenotypic differentiation in *Mimizuku* has progressed more rapidly than has genetic differentiation.

The tribe Bubonini consists of the large and powerful eagle-owls (*Bubo*), fish-owls (*Ketupa*), fishing-owls (*Scotopelia*) and the Snowy Owl (*Nyctea scandiaca*). The eagle-owls are of Old World origin, 16 of the 18 species occurring in Asia or Africa, and only two, the widespread and polytypic Great Horned Owl (*Bubo virginianus*) and the monotypic Magellanic Horned Owl (*Bubo magellanicus*), inhabiting the New World. The last-named, although described as a species as early as 1828, has long been considered a race of the Great Horned Owl. Differences in voice, morphology and DNA, however, indicate that it is a separate species. The Rock Eagle-owl (*Bubo bengalensis*) of India and the Pharaoh Eagle-owl (*Bubo ascalaphus*) of North Africa have been treated as subspecies of the Eurasian Eagle-owl by many authorities; D. Amadon and J. Bull, however, considered all three to represent a superspecies complex, a conclusion that is also supported by recent analysis of the cytochrome-*b* gene. In addition, the Greyish Eagle-owl (*Bubo cinerascens*) of Africa seems better treated as a distinct species. Until recently considered a northern and western race of the Spotted Eagle-owl (*Bubo africanus*), it differs importantly from that species in having dark brown instead of yellow irides, as well as showing other less marked differences in plumage and size.

Eagle-owls and fish-owls are morphologically and genetically similar and are almost certainly close relatives; sometimes both groups are placed in *Bubo*. However, fish-owls differ from eagle-owls in having unfeathered toes and tarsi, spine-like scales on the soles of their feet, and a poorly developed facial disc. Each of these differences can be linked to the fact that *Ketupa* species feed almost exclusively on fish and other aquatic organisms. Blakiston's Eagle-owl (*Bubo blakistoni*) of eastern Asia was long considered to be a *Ketupa*, but it is extremely similar to the Eurasian Eagle-owl osteologically, and also has feathered tarsi.

The three species of *Ketupa* occur in tropical latitudes in Asia. The Tawny Fish-owl (*Ketupa flavipes*) and the Buffy Fish-owl (*Ketupa ketupu*) have relatively restricted adjoining ranges in and near South-east Asia, and are very closely related. The Brown Fish-owl (*Ketupa zeylonensis*) has a wider distribution that encompasses parts of the ranges of the other two species.

The fishing-owls are confined to Africa, where they seem to function as ecological equivalents of the Asian fish-owls. *Scotopelia* shares with *Ketupa* the unfeathered tarsi, spiny scales on the feet, and the poorly developed facial disc; it differs from *Ketupa* in lacking ear-tufts and in possessing loose feathering that gives the head a shaggy appearance.

The final member of the Bubonini, the Snowy Owl, is so distinctive in plumage and behaviour that it is placed in the monotypic genus *Nyctea*. The breeding range of this huge white owl is restricted to Arctic tundra in the Holarctic region. Despite obvious differences in outward appearance, *Nyctea* is very similar to *Bubo* osteologically and genetically, and might perhaps be placed between *Bubo* and *Ketupa* in recognition of this similarity. *Nyctea* differs from *Bubo* in having exceptionally dense plumage, an obvious adaptation to cold temperatures, and in exhibiting sexual dichromatism in which the female is more heavily pigmented than the male.

The tribe Strigini contains the wood-owls (*Strix*, *Pulsatrix*), the Maned Owl (*Jubula lettii*), and the Crested Owl (*Lophostrix cristata*). An additional genus, *Ciccaba*, was separated from *Strix* by Peters on the basis of the size of the external ears and their dermal flaps, but subsequent work by K. H. Voous showed that these genera could not be reliably separated by ear characters. N. L. Ford found no osteological characters that distinguished the two genera and recommended that they be merged, a conclusion also supported by DNA-DNA hybridization data.

The 19 species of *Strix* are relatively large owls that occupy a variety of forested habitats. They are absent from Australasia, whereas ten species are restricted to the New World and eight to the Old World, and one, the Great Grey Owl (*Strix nebulosa*), is Holarctic. Four of the five *Strix* that have traditionally been placed in *Ciccaba* inhabit humid forest in the Neotropics: these are the Mottled (*Strix virgata*), Black-and-white (*Strix nigrolineata*), Black-banded (*Strix huhula*) and Rufous-banded Owls (*Strix albitarsis*). The fifth, the African Wood-owl (*Strix woodfordii*), is the sole member of *Strix* that occurs in the Afrotropical region.

The widespread Tawny Owl of Eurasia and the uncommon Hume's Owl (*Strix butleri*) of the Middle East have been considered conspecific by some authorities. However, studies of

The taxonomy of the Striped Owl has been argued over for some years. Originally placed in a monotypic genus Rhinoptynx, it was later placed in Asio on the basis of similarities in cranial characters. Subsequent work, however, appeared to identify subtle differences between the two in these same characters of cranial morphology, and it was then suggested that Rhinoptynx should really be merged with Pseudoscops, both being equally primitive forms.

[*Asio clamator clamator*, Minas Gerais, Brazil. Photo: Luiz Claudio Marigo]

*In tandem with debate over the taxonomic validity of Rhinoptynx, an unpublished analysis of a specimen of the Stygian Owl found that bird, too, to be closely allied to Pseudoscops. With the advantage of modern methods of molecular-biological analysis, however, it has recently been shown that both the Striped Owl (*Asio clamator*) and the Stygian Owl do in fact belong with other *Asio* species. Thus, the Jamaican Owl remains the sole member of the genus *Pseudoscops*.*

[*Asio stygius stygius*, Araçuaí, Minas Gerais, Brazil. Photo: Edson Endrigo]

The Strigidae family contains many examples of taxa which pose problems in terms of their classification. A good case is presented by the African Long-eared Owl. This bird has often been considered a subspecies of the Northern Long-eared Owl (*Asio otus*), but it is larger and darker than that species, and its chequered underparts, as well as its more powerful feet and bill and its vocal characters, appear sufficiently different that it is now generally regarded as a full species.

[*Asio abyssinicus abyssinicus*,
Bale Mountains, Ethiopia.
Photo: Göran Ekström]

When considering whether a subspecies is sufficiently distinct to have reached the level at which it may be treated as a full, separate species, it is important to determine to what extent, if any, it intergrades with other populations of the species in question. The large and pale northern race of the Great Horned Owl would appear distinctive enough, but the situation is complicated by the fact that intergrading populations occur at the boundaries between races. Even the validity of some subspecies is controversial.

[*Bubo virginianus subarcticus*,
northern British Columbia,
Canada.
Photo: Kenneth Fink/Ardea]

nucleotide sequences in the cytochrome-*b* gene by Heidrich and Wink indicate that Hume's Owl is a valid species and suggest that it is actually more closely related to the African Wood-owl than to the Tawny Owl. Further, the work of R. Straneck has demonstrated that the northern population of the Rufous-legged Owl (*Strix rufipes*) is a distinct species, the Chaco Owl (*Strix chacoensis*), which differs from southern birds in its vocalizations and its plumage colour; together, these two form a superspecies that occurs throughout much of southern South America. Although perhaps of no taxonomic significance, an interesting situation has occurred in western North America, where the widespread Barred Owl (*Strix varia*) has recently colonized the more restricted range of the Spotted Owl (*Strix occidentalis*). Between 1989 and 1992, four hybrids were recorded in Oregon and Washington, USA, raising the question of whether the expanding Barred Owl population is having a detrimental effect on the threatened Spotted Owl (see Status and Conservation).

In the tropical rainforest of Central and South America, the three *Pulsatrix* species form a group of large, striking owls, all having a dark face with contrasting light "spectacles" that give the birds a scowling appearance. Formerly thought to be allied with *Bubo*, *Pulsatrix* is clearly closer to *Strix* in its osteology. The widespread and fairly common Spectacled Owl (*Pulsatrix perspicillata*) occurs from southern Mexico to Argentina and consists of six subspecies. In contrast, the rare and little-known Band-bellied Owl (*Pulsatrix melanota*) and Tawny-browed Owl (*Pulsatrix koeniswaldiana*) occupy restricted and non-overlapping ranges in western and eastern South America, respectively.

Almost nothing is known about the biology of the two species in the monospecific genera *Lophotrix* and *Jubula*, and their taxonomic affinities are unclear as well. They have been linked with *Otus* and *Bubo*, and some authorities merge the two genera, recognizing only *Lophotrix*. Ford placed them in the tribe Otini on the basis that they shared cranial characters with *Otus*. Subsequent work by R. W. Storer indicated that *Lophotrix* was closer to *Pulsatrix*, the two showing similarities in the postcranial skeleton and in the juvenile plumage. Following Storer, the present treatment places *Lophotrix*, and by extension *Jubula*, in the tribe Strigini.

Surniini is the largest of the three tribes in Surniinae and includes *Glaucidium*, the second most numerous genus of owl. Three of the five genera are monospecific. The Northern Hawk-owl (*Surnia ulula*) is a long-tailed, medium-sized inhabitant of boreal forest in the Old and the New Worlds. Genetic analysis indicates that *Surnia* shares a common ancestor with *Glaucidium*. The Long-whiskered Owlet (*Xenoglaux loweryi*) is known from only five specimens collected on the east slope of the Andes in Peru. The fan-like extension of its facial ruff is unique among owls. Very little is known about this peculiar little owl (indeed, *Xenoglaux* translates as "strange owl") other than that it appears to be closest to *Micrathene* and *Glaucidium*. The Elf Owl is the world's smallest owl and the sole member of the genus *Micrathene*. It occupies deserts and open woodland in the southwestern USA and northern Mexico. *Micrathene* shares cranial characters with *Glaucidium* and *Athene*, but it is unclear which genus is the closer relative.

The 31 species of *Glaucidium* are small diurnal or crepuscular owls that prey on insects, reptiles and small birds. They can be conveniently divided into two groups: the pygmy-owls of the New World and temperate Eurasia, with 19 species and one species, respectively; and the eleven owlets of Africa and tropical to subtropical Asia, six of which inhabit the former and five the latter. Classification of *Glaucidium* is complicated by the fact that some taxa exhibit intraspecific plumage dichromatism, some are very similar in plumage and morphology, and many are unstudied in the wild. Consequently, the taxonomy within the group is in greater flux than is that of any other genus of owl. The rapid progress in our understanding of the genus is reflected by the fact that, as recently as in 1988, Amadon and Bull recognized only 15 species of *Glaucidium*. Recent work on vocalizations and genetics, especially in the New World tropics, has more than doubled that number.

C. König's 1991 monograph on pygmy-owls of the South American Andes was the first comprehensive treatment of multiple species of *Glaucidium* based on vocalizations. König classified the taxa into three groups: species uttering long series of single, equally spaced notes; those uttering trills and single notes, or trills only; and species uttering note sequences mainly in cou-

plets. The first group was represented by the Ferruginous (*Glaucidium brasilianum*), Peruvian (*Glaucidium peruanum*) and Austral Pygmy-owls (*Glaucidium nanum*); the second by the Andean (*Glaucidium jardinii*), Yungas (*Glaucidium bolivianum*) and Amazonian Pygmy-owls (*Glaucidium hardyi*); whereas series of couplets were given by the Least Pygmy-owl (*Glaucidium minutissimum*). Two of these species, the Yungas and the Peruvian, were new to science, and one, the Austral Pygmy-owl, was elevated from a subspecies of the Ferruginous Pygmy-owl. More recent work on the Ferruginous Pygmy-owl complex suggests that the two taxa *ridgwayi* and *cactorum* from Central America, Mexico and the south-western USA, currently treated as subspecies of the Ferruginous, probably constitute a separate species. Until further details are available, however, it is probably better to consider the Ferruginous Pygmy-owl to be a very widespread species consisting of some nine races. Again, J. Fjeldså and G. Engblom have discovered that the recently described Peruvian Pygmy-owl actually appears to constitute two species, one on the Pacific slope and one on the Amazonian, the two differing notably in both morphology and vocalizations.

Until very recently, the Least Pygmy-Owl was regarded as comprising eight subspecies, distributed from Mexico to central South America. In contrast to some other *Glaucidium* species, taxa in the *minutissimum* complex do not exhibit plumage dichromatism. S. N. G. Howell and M. B. Robbins revised the taxonomy of this group in 1995, focusing on analyses of vocalizations and plumage. Their work revealed that four species were involved: the Colima Pygmy-owl (*Glaucidium palmarum*) from western Mexico, including the former subspecies *oberholseri* and *griscomi*; the Tamaulipas Pygmy-owl (*Glaucidium sanchezi*) from north-eastern Mexico, previously a subspecies; the Central American Pygmy-owl (*Glaucidium griseiceps*) from south-eastern Mexico to northern South America, including the former subspecies *rurum* and *occultum*; and, finally, the Least Pygmy-owl from south-eastern Brazil and adjacent Paraguay. Howell and Robbins also placed the newly described Amazonian Pygmy-owl from Brazil and the Subtropical Pygmy-owl (*Glaucidium parkeri*) from Ecuador and Peru in the *minutissimum* complex. The first of these was not considered

part of the *minutissimum* complex by König (see above), but Howell and Robbins placed it there on the basis of plumage, size and distribution and in recognition of the variation in vocalizations exhibited by members of the complex. Thus, even with data on vocalizations, the taxonomic status of some *Glaucidium* owls may be far from clear!

Another difficult group is that which includes the Mountain Pygmy-owl (*Glaucidium gnoma*). This species was formerly considered to consist of seven subspecies ranging from south-western Canada to Honduras, but differences in plumage and vocalizations have led several authorities to split it into four species: the Northern (*Glaucidium californicum*), the Mountain, the Guatemalan (*Glaucidium cobanense*) and the Baja Pygmy-owls (*Glaucidium hoskinsii*). The first two range from south-western Canada to the south-western USA and from northern Mexico to Central America, respectively, with the Guatemalan species in the highlands of southern Mexico and Guatemala, and the Baja Pygmy-owl confined to Baja California Sur, in Mexico. The present treatment of the *gnoma* complex is based largely on the recent work of P. Heidrich and associates and of S. N. G. Howell and S. Webb. Genetic analyses support the split of *gnoma* and *californicum*, and work that is currently under way is certain to shed further light on species limits in this difficult group.

The Eurasian Pygmy-owl (*Glaucidium passerinum*) is the only *Glaucidium* in the western Palearctic and has the northernmost distribution of any member of its genus. Because of its similar appearance to the Northern Pygmy-owl of temperate North America, the two have been considered conspecific by some authorities. However, DNA studies have shown that the Eurasian species is much more closely related to the Pearl-spotted Owlet (*Glaucidium perlatum*) of sub-Saharan Africa than to the Nearctic species.

Athene, the last genus in the tribe Surniini, consists of four short-tailed, plump species. The Burrowing Owl is widely distributed in the New World and differs from other *Athene* in having longer legs and a decidedly terrestrial way of life: it inhabits grassland and savanna from southern Canada to the tip of South America and nests below ground in the burrows of fossorial mammals. The Burrowing Owl is often placed in the monotypic ge-

Intensive field research in the last decade of the twentieth century has led to the discovery of a comparatively large number of new taxa of Strigidae. One example is the Peruvian Pygmy-owl. Described as recently as in 1991, it has already been found probably to comprise two distinct species, which differ notably in both voice and morphology. The name "peruanum" is applicable to birds of the amazonian slope, like this one, while the description of the pacific-slope taxon is currently in the process of being done.

[*Glaucidium peruanum*, El Tambo, east of Salinas, Guayas, Ecuador. Photo: Robert Behrstock]

It is not only new species of owl that have been discovered in recent years. Even some genera remained unknown until relatively late, and this was the case with the Long-whiskered Owlet of the Andean slopes of northern Peru. This very rare but highly distinctive, tiny bird, with extremely long facial whiskers, was not discovered until 1977. It is so unlike any other strigid in its morphology that it is afforded its own monotypic genus.

[*Xenoglaux loweryi*, Abra Patricia, San Martín, Peru. Photo: John P. O'Neill]

nus *Speotyto*, but osteological similarities, as well as similarities in outward appearance and in nucleotide sequences, warrant its placement in *Athene*. The Little Owl occurs in desert and semi-open country throughout the Palearctic Region; it forms a superspecies with the Spotted Owlet (*Athene brama*) of India and Indochina. Last but not least, the rare and little-known Forest Owlet (*Athene blewitti*) occurs in deciduous forest in India. Known from only a handful of specimens, and formerly considered extinct, it was rediscovered in 1997 after an "absence" of more than 110 years (see Status and Conservation).

The four species of the saw-whet group, genus *Aegolius*, are small, short-tailed, tuftless owls that inhabit woodland. The sole members of the tribe Aegoliini, they exhibit a striking asymmetry in the size and shape of their ear openings (see Morphological Aspects). The Boreal Owl (*Aegolius funereus*) is Holarctic, whereas the Northern Saw-whet Owl (*Aegolius acadicus*), Unspotted Saw-whet Owl (*Aegolius ridgwayi*) and Buff-fronted Owl (*Aegolius harrisi*) belong to a superspecies complex distributed from central Canada and the USA south through Central America to the southern half of South America. Genetic data indicate that Boreal Owls diverged from Northern Saw-whet Owls about 6 million years ago, and that Buff-fronted Owls shared a common ancestor with the latter. The adult Unspotted Saw-whet Owl bears a striking resemblance to a Northern Saw-whet Owl in juvenile plumage, and it has been suggested that it is a southern race of that species. However, until genetic data are available for the Unspotted Saw-whet, the two taxa are best treated as separate species.

The tribe Ninoxini contains three Old World genera. The 19 species of *Ninox* are confined to the Australasian and Oriental Regions, with two exceptions: the Brown Hawk-owl (*Ninox scutulata*), which extends from India and Indonesia north to Siberia and Japan; and the White-browed Hawk-owl (*Ninox supercilialis*), which is endemic to Madagascar. Aptly known as hawk-owls, the long tail, narrow wings and poorly developed facial disc give some *Ninox* a hawk-like demeanour. The highest diversity of *Ninox* is in Australasia. The three species that are widely sympatric in Australia come in small, medium and large sizes and, accordingly, take different-sized prey. Smallest of them is the Southern Boobook (*Ninox boobook*), with the Barking Owl (*Ninox connivens*) intermediate and the Powerful Owl (*Ninox strenua*) the largest.

Most of the other *Ninox* have restricted ranges that do not overlap with those of their congeners, except for the above-mentioned Brown Hawk-owl. The distribution of taxa in the Bismarck Archipelago and nearby Solomon Islands is especially interesting. The monotypic Manus Hawk-owl (*Ninox meeki*) is the sole *Ninox* on its namesake island group, whereas the larger island of New Britain is inhabited by the monotypic New Britain Hawk-owl (*Ninox odiosa*) and the polytypic Bismarck Hawk-owl (*Ninox variegata*), which also occurs on nearby New Ireland. Just to the south-east, seven subspecies of the Solomon Hawk-owl (*Ninox jacquinoti*) have non-overlapping ranges on the various islands in the Solomon chain. The Christmas Hawk-owl (*Ninox natalis*), endemic to Christmas Island, south of Java in the Indian Ocean, was formerly considered to be a subspecies of the Moluccan Hawk-owl (*Ninox squamipila*), which has its distribution centred some 2500 km away to the north-east of Christmas Island, at the far end of Indonesia. Elevation of the Christmas Island Hawk-owl to a full species was based on recent analyses of mitochondrial DNA and plumage colour and pattern conducted by J. A. Norman and associates. Several other insular taxa in the Moluccan Hawk-owl complex probably warrant species status too (see Status and Conservation), and current research on the Philippine Hawk-owl (*Ninox philippensis*) suggests that at least two species are involved. Overall, *Ninox* remains a very poorly known genus, and future work will no doubt increase the number of species recognized, as evidenced by a new species from Indonesia that has recently been discovered and that is likely to be described before the current year is out.

The remaining members of the Ninoxini are the Papuan Hawk-owl (*Uroglauis dimorpha*) of New Guinea and the Laughing Owl (*Sceloglauis albifacies*) of New Zealand. The strongly barred dorsum and tail of the Papuan Hawk-owl are very similar

to those of the Rufous Owl (*Ninox rufa*), which also occurs in New Guinea; the underparts of the two species differ in being streaked in *Uroglauis* and strongly barred in the Rufous Owl. Sadly, the Laughing Owl may be extinct (see Status and Conservation). It differs from *Uroglauis* and most species of *Ninox* in having long legs and a rather well-developed facial disc.

Asioninae consists of nine species of medium-sized "eared" owls. Despite the paucity of species in the subfamily, the generic limits are unclear. Peters recognized four genera in the group:

Perhaps it is not so surprising that new species of owl are still being named at the very end of the twentieth century. The nocturnal and generally very secretive habits of these birds, in addition to the often remote places in which they live, have effectively protected them from human contact for a prolonged period of time. In 1999, two new species were described for the first time: the Sangihe Scops-owl from the small Indonesian island of that name; and, from the other side of the world, the Cloudforest Pygmy-owl, which is confined to cloudforest on the Pacific slope of the Andes from Colombia to western Ecuador, perhaps extending into northern Peru. Further research will be needed on these newly named species in order to confirm their exact relationships with other members of their respective genera.

Below: *Glaucidium nubicola*, Alto de Pisones, Risaralda, Colombia. Photo: F. Gary Stiles]

A major taxonomic headache is presented by the genus *Otus*. Not only does it contain a large number of species, some extremely similar to others, but many of its members are very poorly known. In addition, individual variation within species can be rather wide. As a consequence, it is only through intensive research that scientists have been able to determine that some forms should be split as separate species, while others have been "lumped". The six species here are all Neotropical screech-owls.

Rhinoptynx, *Asio*, *Pseudoscops* and *Nesasio*. Ford used cranial characters to merge *Rhinoptynx* and *Pseudoscops* with *Asio*. More recently, Olson identified subtle differences in cranial morphology that separate the more derived *Asio* from the comparatively primitive *Pseudoscops* and *Nesasio*; moreover, he posited that *Rhinoptynx* and *Pseudoscops* belonged together in *Pseudoscops*. Olson's subsequent, albeit unpublished analysis of a specimen of the Stygian Owl (*Asio stygius*) showed it to be allied with *Pseudoscops* as well. In contrast, molecular analyses conducted by Wink and Heidrich indicated that the Striped Owl (*Asio clamator*) and the Stygian Owl belong in *Asio*, which is closer to the more traditional view. Accordingly, the present treatment considers *Pseudoscops* to include only the Jamaican Owl (*Pseudoscops grammicus*), with all other asionine taxa except the Fearful Owl (*Nesasio solomonensis*) placed in *Asio*.

Two of the seven species of *Asio* are widespread in the Old and New Worlds, the Striped and the Stygian Owls are endemic to the Neotropics, and three occur in Africa. The Northern Long-eared Owl occupies grassland, shrubland and open forest throughout the Nearctic and Palearctic Regions, whereas the Short-eared Owl is restricted to open grassland and marshes over much the same range but also occurs in South America. Both species have long wings and light wing-loading, and hunt by coursing low over open country. The African Long-eared Owl (*Asio abyssinicus*) and the Madagascar Long-eared Owl

(*Asio madagascariensis*) constitute a superspecies with the Northern Long-eared Owl; the former is restricted to Central and East Africa and the latter to Madagascar. The Marsh Owl (*Asio capensis*), which occurs in grassland and marshland throughout much of Africa south of the Sahara Desert, is ecologically and morphologically similar to the Short-eared Owl and perhaps is its closest relative.

Finally, the Fearful Owl is endemic to the Solomon Islands, and its habits are rather poorly known. It is the only asionine that lacks ear-tufts, and its beak and talons are unusually large for its body size. Presumably, it occupies a niche filled by the larger species of *Ninox* elsewhere in Australasia. Although it is positioned last in the species list of Strigidae, the Fearful Owl perhaps belongs after *Pseudoscops* in recognition of the relatively primitive cranial morphology that it shares with this genus, as opposed to *Asio*.

Morphological Aspects

Strigids vary one-hundredfold in body mass, from the tiny Elf Owl to the massive female Eurasian Eagle-owl. Despite this tremendous variation, however, body proportions and basic morphology are rather similar throughout the family. Several distinctive features are found in almost all species. These include

The difficulties in classifying *Otus* species are, if anything, even greater in the Oriental Region. Here, there are many distinct populations of scops-owls which are poorly known, with restricted ranges, but at the same time a fair number of others which are more widespread and highly variable. As with the Neotropical screech-owls, only much further research, especially of vocalizations, will lead to a proper understanding of the taxonomy of this fascinating genus.

a large head with a round facial disc encircling the eyes, a moderately short tail, and soft, cryptically coloured plumage. Members of Strigidae differ from those of the other owl family, Tytonidae, in having a round rather than a heart-shaped facial disc, and four rather than two notches in the sternum. Strigids also have a rounder skull with relatively larger orbits, a furcula that is not fused to the sternum, and a naked uropygial gland. In addition, the third toe is longer than the second in strigids, whereas the two toes are equal in length in tytonids, and the nail on the third toe has a smooth cutting edge, as opposed to a comb-like, or pectinate, edge in tytonids.

As would be surmised for an exclusively raptorial family, no extant species is flightless, and flight is the main form of locomotion used during foraging. Some species, such as the Burrowing Owl, are somewhat terrestrial in habits, with longer legs for pursuing insect prey on foot. Others, notably the hawk-owls and pygmy-owls, capture flying birds or, as is often the case in some *Ninox* species, fruit-bats and gliding marsupials, and these owls have relatively long tails for increased agility.

Many owl species with distributions covering a broad range of latitudes conform to Bergmann's Rule, which states that selection favours a larger body at higher, cooler latitudes. The largest Brown Hawk-owls, for instance, occur at the northern end of the species' range in Ussuriland, in the Russian Far East, whereas the smallest are found in the tropical forest of Java.

Similarly, the largest Burrowing Owls occur in southern South America and the smallest on the equatorial savannas of Brazil. In addition, Kelso's Rule was formulated for owls, stating that the feathering on the toes and tarsi is more extensive in species that inhabit high latitudes than in those that occur in lower, warmer latitudes. Indeed, the tarsi and toes of the Snowy Owl have extremely dense feathering, and those of the other Holarctic species also are heavily feathered. In contrast, the feet of many tropical species are sparsely feathered, and those of some, including the Bare-shanked Screech-owl (*Otus clarkii*) and the Colombian Screech-owl, are virtually naked. Kelso's Rule works within species, as well: Barred Owls of the northern, nominate race have dense feathering on their tarsi and toes, whereas the Florida race *georgica* has feathered tarsi but unfeathered toes. Similarly, Stygian Owls from Mexico and Central America, race *robustus*, have sparsely feathered toes, but those from Brazil, the nominate subspecies, have bare toes.

Most of the morphological features distinctive of strigids arise from the fact that they are predatory and nocturnal. These two forces have produced specialized plumage, ears, eyes, bill and feet. Plumage colours are dominated by browns and greys that make most species highly cryptic, presumably to allow the birds to roost undisturbed during the daytime (see General Habits). The plumage colour generally follows Gloger's Rule, with dark brown colours in humid climates, as shown for example by

Crested and Spectacled Owls in Neotropical rainforest, and sandier tones in arid areas, as illustrated by Hume's Owl of the deserts of Arabia and other parts of the Middle East. Again, the trend also holds within species. This is demonstrated, for instance, in the Northern Saw-whet Owl, where the dark brown race *brooksi* occupies the temperate rainforest of the Queen Charlotte Islands; it is also reflected by the pale forms of the Little Owl and Eurasian Eagle-owl in the more arid portions of Eurasia.

Because most owl species are active only at night, sexual-selection pressure for the colourful plumages typical of many males of other bird groups is largely absent. The Snowy Owl, which breeds during the 24-hour daylight of the Arctic summer, shows the most sexual dimorphism in colour, with adult males essentially pure white and adult females and immatures speckled and barred with dark brown. Subtle differences between the sexes in plumage colour occur in a few other species, such as the Northern Long-eared, Marsh and Short-eared Owls, in which females are darker and rustier than males, particularly on the tarsus, belly, underwing and facial disc, and in the Burrowing Owl, females of which tend to be darker and more heavily marked than males.

Owl feathers lack an aftershaft but have a downy base. The flight-feathers are covered with a velvety pile that is very soft to the touch, quite unlike the stiff, glossy feel of the flight-feathers of most other bird species, and in many strigids the leading edges of the outer primaries have a short, comb-like fringe that deflects air upwards as it passes over the wings during flight. These two features apparently combine to produce the silent flight so typical of owls, allowing them to fly towards prey using auditory cues that would normally be obscured by the sound of flapping wings. Largely diurnal species such as some *Glaucidium* lack the comb-like fringe on their primaries, as do *Ketupa* and *Scotopelia* owls, and the flight of these species is not as quiet as that of other owls. W. Neuhaus and colleagues, however, report that experimental removal of the comb-like fringe on the primaries of species normally possessing it had no effect on wing noise during flight.

The silent flight of owls is probably enhanced by the light wing-loading typical of the family. Most owls have large wings in relation to their body mass. In some species, such as most *Asio*, this is clearly an adaptation for spending long periods of time flying in search of prey, whereas in others it may simply make it easier to fly silently and with agility. Species that hunt from a perch generally have rounded wings, and those that course over fields have longer, less rounded wings.

Owls in temperate regions replace their feathers in summer and autumn, whereas tropical species have more extended or year-round moulting regimes. The Eurasian Scops-owl suspends moult of its flight-feathers during migration and completes it on the wintering grounds, but the closely related Flammulated Owl of North America seems to complete its flight-feather moult on the breeding grounds. Many owls shed all of their rectrices nearly

The White-throated Screech-owl appears to be an aberrant form of Otus, lacking the ear-tufts so typical of that genus. Indeed, some taxonomists believe that it should not be included in Otus at all. Although DNA studies have shown this species to be quite closely related to the other New World screech-owls, it may perhaps be better placed in a separate genus, or subgenus, Macabra.

Despite an enormous variation in size and weight, the strigids share a similar basic morphology, typified by the Rufous-legged Owl. With few exceptions, they all have a large, fairly rounded head, a relatively short tail and, perhaps most distinctive of all, a rounded facial disc with large eyes. In most cases, the plumage is soft and markedly cryptic, effectively concealing the birds at their daytime roosts.

[*Strix rufipes rufipes*, Patagonia, southern Argentina.
Photo: François Gohier]

Large, broad, rounded wings characterize the majority of the Strigidae. The flight-feathers are covered with a very soft, velvety pile which, together with a peculiar comb-like structure along the leading edge of the outer wing of most species, produces a totally silent flight, although the exact role played in this by the comb-like primary fringe is uncertain. A further characteristic of the family, visible on this Spotted Eagle-owl, is the sharp, curved talons, a vital adaptation since all strigids catch their prey with the feet.

simultaneously or over a period of a few days, leaving them tail-less for a short time after the breeding season.

In some genera, for example *Athene*, the post-breeding or pre-basic moult is complete, but many species have an incomplete moult of the primary and secondary feathers. Some captive Boreal Owls, for example, have been known to retain a few juvenile primaries for up to five years. As a result, complex patterns of different-aged remiges are often present on the wings of adults. The extent of remigial moult is related to breeding effort in the Ural Owl (*Strix uralensis*); H. Pietiäinen and associates found that the number of flight-feathers an individual replaced each year was inversely related to the number of young it had raised that season, and non-breeders moulted the largest number of flight-feathers.

Age-related differences in plumage, if present at all, are usually subtle. The genera *Ptilopsis*, *Glaucidium* and *Aegolius*, however, have non-downy juvenile plumages that are distinctly different from those of the adults. Indeed, the juvenile Northern Saw-whet Owl was initially described as a different species, the "White-fronted Owl". The plumages of immature Snowy Owls are generally more heavily barred with brown than their adult equivalents. Several species show changes in the pattern of tail barring between yearling and adult birds, the adults generally having fewer and wider bars; the Great Horned, Spotted, Barred and Northern Long-eared Owls come in this category.

Dark nape patches, in the form of two spots of dark feathers edged in white, which thus resemble eyes, are a remarkable plumage pattern found in many *Glaucidium* owls and in the Northern Hawk-owl. These species are active during the day, and the "false eyes" presumably fool larger predators such as hawks (Accipitridae), and perhaps smaller mobbing birds, into thinking that the owls are always watching them and are therefore aware of their presence. The fact that some *Glaucidium* species have this plumage pattern and others do not is interesting. Whether its presence relates to size (several of the species lacking the pattern are relatively large), behaviour, or simply a shared evolutionary history is unknown. Two of the species that do not possess "false eyes", the African Barred Owlet (*Glaucidium capense*) and the Sjöstedt's Owlet (*Glaucidium sjostedti*), are partly nocturnal. Others lacking the pattern, such as the Asian Barred Owlet (*Glaucidium cuculoides*), are largely diurnal, but they may share

the African Barred Owlet's habit of hunting from more hidden perches in denser forest and would thus be less prone to discovery by would-be predators or mobbing passerines. All of the New World *Glaucidium* have the "false eyes".

Some nocturnal birds, notably a few of the tropical caprimulgids (see page 309), have evolved spectacularly long streamers on their wings or greatly elongated tail feathers for use in courtship and territorial displays, but such dramatic structures are lacking in strigids. Many strigids do, however, have a plumage feature that alters their silhouette: the so-called "ear-tufts" on the head. Well-developed ear-tufts are restricted to nocturnal species, lending some credence to the theory that they function primarily to camouflage owls on daytime roosts: raised ear-tufts break up the outline of a roosting owl and enhance the impression that the cryptically coloured bird is part of the tree in which it is perched. Some researchers have suggested that these tufts are used for behavioural signalling and species recognition, but these proposals remain speculative. Ear-tufts are common among the Striginae and the Asioninae, but more or less lacking in the Surniinae. Nevertheless, many species without noticeable ear-tufts, such as the Snowy Owl and some *Glaucidium* and *Aegolius* owls, raise the feathers at the corners of their forehead when excited (see General Habits), and this can give the impression of small ear-tufts.

Perhaps the most distinctive feather structure associated with owls is the facial disc. This is composed of feathers with very open vanes and it lies over paired (one on each side of the face) layers of densely packed feathers with large rachides and reduced vanes. The latter layers are termed the facial ruff and are clearly associated with hearing. They are inserted behind the ear openings in a special flap of skin, and they form more or less solid, roughly parabolic troughs surrounding and leading to the ear openings themselves. The facial ruff, and the facial disc that covers it, are very large in highly nocturnal species such as the Buff-fronted Owl, and in species that can detect prey under the snow, such as the Great Grey Owl; they are smaller and less well developed in diurnal or crepuscular species such as the Snowy Owl, *Ninox*, the Northern Hawk-owl, and *Glaucidium* species, all of which hunt more visually. The facial ruff may provide a tenfold increase in the sound pressure delivered to the ears, and it probably has an important function in sound localization as well. The motor muscles associated with the skin around the ear

openings probably allow owls to change the shape of the facial ruff, directing it towards sounds in the same manner as many mammals move their external ears.

The hearing of owls is more sensitive to low-frequency sounds than is that of most birds and is sensitive across a wide range of frequencies. Most strigids have excellent sensitivity down to at least 250 Hz, and their high-frequency threshold ranges from about 7 kHz in the Great Horned Owl to 11 kHz in the Northern Long-eared Owl and the Mottled Owl. The frequency at which owl hearing is most sensitive ranges from 500 Hz in the Great Horned and Mottled Owls to 6 kHz in the Northern Long-eared Owl, the African Wood-owl and the Tawny Owl.

In most owls, the external ear openings are very large and are surrounded by folds of skin with associated motor muscles. These openings are long, crescent-shaped structures that are quite different from the tiny circular openings found in other birds. At least five genera, comprising four separate phylogenetic lines, have asymmetrical external ears in which the right and left ear openings are different in size or shape or both. This phenomenon is seen in *Bubo*, *Strix*, *Aegolius*, *Pseudoscops* and *Asio*. The asymmetry is restricted to the fleshy parts of the ear openings in *Bubo*, *Pseudoscops*, *Asio* and most *Strix*, but in *Aegolius* and in two species of *Strix*, the Ural and Great Grey Owls, the bony structure of the ear is markedly asymmetrical as well.

In *Aegolius*, the slit-like ear openings in the skin are symmetrical and extend the full height of the skull. The actual openings into the skull, however, are only half the size of the slits in the skin and are highly asymmetrical. The opening on the right is about 6 mm higher than that on the left. In the Boreal Owl, the right ear is up to 50% larger than the left and is directed upwards, whereas the left ear is directed downwards. The skull asymmetry in *Strix* and *Aegolius* does not extend to the middle and inner ears. In Marsh Owls and other members of the genus *Asio*, the right and left ear openings are of the same size and shape but are situated in different vertical positions on the head. The remarkable asymmetry in ear size and shape enables these owls to localize sounds in the vertical as well as the horizontal plane, thus allowing them to determine the exact location of prey by sound alone. For example, Great Grey Owls can pinpoint and

capture mice under 45 cm of snow, and fossorial rodents beneath more than 2 cm of soil.

Owls use differences in interaural time and interaural intensity to localize the horizontal direction (azimuth) of a sound. In other words, they compare the time at which a sound arrives in the left ear with the time when it arrives in the right ear, as well as how loud the sound is in each ear. To localize sounds in the vertical plane, owls compare the intensities of high-pitched sounds in each ear. These sounds must have wavelengths about equal to or shorter than the size of the ear openings; for most owl species, this corresponds to sounds above 5 kHz. Localization is also more accurate if the sounds are complex, consisting of a number of tones with very different wavelengths. Consequently, the rustling sounds made by small mammals in forest leaf litter are ideal for localization by owls.

The Strigidae have relatively large eyes. Indeed, those of some species are larger than the human eye, and even the eye of the medium-sized Tawny Owl is longer than that of a human being. Owl eyes are distinctly tubular in shape and have a lens that is more spherical than that of other birds, so as to maximize retinal image size. The eyes are positioned well apart and on the front of the face, which is flattened in owls, resulting in excellent depth perception. The eyes of a Tawny Owl diverge at an angle of 55°, giving a binocular field of view of 48° and an overall visual coverage of 200°. Owls have not maximized their binocular field of view; to do so would reduce the total visual field to 120°. The accuracy of depth perception through binocular vision is often augmented by owls through head-bobbing and head-weaving. The neural pathways involved in binocular vision have been studied for the Little Owl by P. Bagnoli and V. Porciatti and their respective co-workers, and for the Northern Saw-whet Owl by D. Wylie and associates. These systems are more highly developed in owls than in other birds such as pigeons (Columbidae) and chickens, and they exhibit strong convergence with the condition found in frontally eyed mammals such as monkeys and humans.

All birds' eyes are more or less fixed in their orbits, fully enclosed by the bones of the skull, and their movement is restricted to less than 1° of arc. The relatively long, tubular eyes of owls project well beyond the skull, but are supported by a ring of bony plates called the sclerotic ring. The immobility of the eyes, combined with their forward-pointing aspect, means that an owl has to turn its head to see objects to the side or behind it. To do this, the perched owl can rotate its head more than 270°, a trait that many people consider remarkable. However, a highly flexible neck is not at all unusual among birds, because it is an essential part of their ability to fly. Indeed, recent studies by K. P. Dial and colleagues have shown that, during flight, birds commonly rotate the body through 270° or more while keeping the head level.

Contrary to popular belief, owls cannot see well in extremely dark situations, and they have no difficulty whatsoever in seeing during daylight hours. G. Martin has established that the mean absolute visual threshold, that is the minimum amount of light required to see objects, is about two times lower in Tawny Owls than in humans. The level of variation, however, is such that the most sensitive human eyes would be equal to or better than the least sensitive owl eyes in this regard. Owls fare rather better when compared with diurnal birds such as pigeons, where a hundredfold difference exists in visual sensitivity in low light. Unlike many nocturnal mammals, owls lack a tapetum in the retina, as do all other birds except the caprimulgiforms. The tapetum is a structure that can improve visual sensitivity at night by a factor of about two. Thus, a typical nocturnal mammal such as a house cat has a mean absolute visual threshold about 2.2 times lower than that of a Tawny Owl.

The daylight visual acuity of owls, about 2.5 to 5 minutes of arc, is similar to that of most other birds and better than that of many nocturnal vertebrates such as cats and rats, but it is about five times lower than that of humans and diurnal raptors. Much of the improved visual performance of owls in low light conditions is due to their large pupils. The focal lengths of the eyes of humans and Tawny Owls are very similar, but the larger pupil diameter of the owl creates an image that is about 2.7 times

The amazingly cryptic plumage of strigid owls could not be better illustrated than it is in this shot. A Flammulated Owl sleeping by day in a tree cavity merges so perfectly with the background of the tree's bark that it would pass unseen by all but the most discerning of human eyes. This remarkable camouflage, arising from both the coloration and the pattern of the plumage, also serves to conceal these nocturnal birds from diurnal predators, as well as from the mobbing attentions of smaller birds.

[*Otus flammeolus*, Madera Canyon, Arizona, USA. Photo: Sid & Shirley Rucker/DRK]

The extreme in pale coloration among owls is found, predictably enough, in the Snowy Owl of the circumpolar Arctic. Adult males are essentially pure white, while adult females and immatures, although barred and spotted with dark brown, still appear exceedingly pale.

Note also the densely feathered tarsi and feet of this individual as it balances, wings spread, on a stump amid green grass: in accordance with Kelso's Rule, the toe and tarsal feathering is more extensive in species of colder, higher latitudes than in those inhabiting warmer, lower ones.

Minden Pictures]

brighter than the one perceived by the human eye. For those familiar with a camera lens, the Tawny Owl eye has an f -number of about 1.3, compared with an f -number of 2.1 for a human. This improvement in light-gathering in the owl eye is sufficient for the owl to avoid branches and other obstacles in low light conditions, but it is not enough to allow the owl to see all objects below the forest canopy on a moonless night. Consequently, forest owls must rely on spatial memory to avoid obstructions, or else they probably restrict their activities to the crepuscular hours or to moonlit nights when the light is better.

Owls have a duplex retina that contains both rod and cone receptors. In the retinas of most birds, cone cells far outnumber rod cells, but the owl retina contains many more rods than cones. In the Barred Owl, for example, the ratio of rods to cones is about 10:1. Rod cells are more sensitive to low light, but they give very poor, if any, colour vision. In the vertebrate retina, fine spatial resolution is generally mediated by the fovea. Owls have an unusual mixed fovea that contains both cone cells and rod cells, instead of being composed of cone cells alone. Therefore, they have some ability to see colours, but surely not to the extent of most diurnal birds. For instance, experiments conducted by G. Martin have shown that the Tawny Owl "has a fully functional colour vision system, but one perhaps less capable of making colour discriminations as fine as can be achieved by the pigeon". Little Owls apparently confuse red with dark grey, and electro-retinogram studies by V. Porciatti and colleagues have confirmed the dominance of rod cells in this species. Given their limitations in colour perception, one must wonder why so many strigids have brightly coloured irides.

An owl's bill is rather short and stout, with a sharply hooked upper mandible and sharp cutting edges. The depressed shape may be an adaptation to maximize the field of view for the forward-pointing eyes. The cere is overlain by thick bristles that also point forwards. Owls have zygodactyl feet, the fourth toe being reversible so that the second and third toes face forwards and the first and fourth face backwards. This character is perhaps advantageous when holding prey, although it is not found in the other major group of raptorial birds, the hawks, eagles and falcons (Falconiformes). It is more likely that zygodactyl feet are an adaptation for perching on branches. In *Ketupa* and *Scotopelia* owls, the scales on the soles of the feet are modified into spicules

to aid in holding their slippery piscine prey. Many insectivorous species have unfeathered, rather delicate toes, as opposed to the heavily feathered, powerful toes with heavy talons present on carnivorous species. Pygmy-owls have relatively long toes tipped with long talons that allow them to capture prey up to their own size and larger (see Food and Feeding).

In contrast to the Snowy Owl (*Nyctea scandiaca*), the Jungle Hawk-owl is one of the darkest of all strigids, as befits its humid rainforest habitat. This is a demonstration of Gloger's Rule, with darker plumages found in humid climates and paler ones in drier habitats. The genus *Ninox*, which makes more use of visual cues in hunting, has a less well-developed facial disc than most owls, as also do diurnal species such as the Snowy Owl and *Glaucidium* species.

A particular feature of the Strigidae is the occurrence in many species of polymorphism, a phenomenon especially marked among the *Otus* owls. The Guatemalan Screech-owl, here in its grey-brown morph, occurs also in a rufous morph, and the Vermiculated Screech-owl, shown in its rufous morph, also has a grey-brown morph. Formerly thought conspecific, these two species have been shown to differ vocally and in the extent of their tarsal feathering.

Food ingested by owls passes through the oesophagus into the glandular stomach (proventriculus), then into the muscular stomach or gizzard. Unlike many other bird groups, owls lack a true crop or other dilation of the oesophagus. Food is retained in the stomach for three to 13 hours. Then, 10-12 minutes of vigorous gastric contractions force the liquid digesta into the duodenum while compacting the undigested material that remains in the gizzard. The solid material, consisting of bones and hair if the food was mammalian, bones and feathers if avian, and chitin if from invertebrates, is squeezed into an ovoid pellet and forced back up into the lower oesophagus. From there, the pellet moves upwards by reverse peristalsis and is ejected from the wide-open mouth, this event often being accompanied by convulsions and vigorous shaking of the owl's head.

Owls generally produce one pellet per meal, but some pellets may contain the remains of several prey items that were eaten in quick succession. D. Chitty, working with captive Short-eared Owls, has shown that the time interval between a meal and pellet production is correlated with meal size; a pellet was produced within three hours after a meal of 10 g, but it took eight hours to produce a pellet after a meal of 40 g. G. E. Duke and associates found that the meal-to-pellet time interval was shortened in captive Great Horned Owls that were fed in the morning rather than in the evening, and also when the owls could see other conspecifics. It was not shortened, however, if the owls were presented with food before they had finished digesting an earlier meal.

Owl pellets contain about ten times as much bony material as those ejected by diurnal birds of prey such as hawks. They therefore provide an ideal means of studying food habits (see Food and Feeding). The relatively high amount of bone in their pellets results in part because owls are less able than hawks to digest bone. The gastric fluid of owls has a pH of about 2.35, compared with 1.6 in hawks. Because pH measures the logarithm of the reciprocal of hydrogen ion concentration, the gastric juice of hawks is about six times more concentrated than that of owls. In addition, owls appear to be more likely than hawks to swallow their prey whole, which means that they ingest more bones with their meal.

Interestingly, owls that hunt on the wing may have a smaller digestive tract than those that hunt from perches. N. W. Barton and D. C. Houston found that the Northern Long-eared Owl, whose foraging habits are typically more aerial, has a significantly lighter digestive tract and a shorter small intestine than does the perch-hunting Tawny Owl. Presumably, this reduction in mass is an adaptation to reduce flight costs in Northern Long-eared Owls.

A particularly interesting aspect common to most owls and diurnal raptors is that they exhibit reversed sexual dimorphism in size, often referred to as "RSD", whereby females are generally larger than males in structural characters and body mass. The difference is greatest in species such as the Mottled, Great Grey and Boreal Owls, in which the females can weigh about 40% more than the males. There are a few exceptions to this pattern of reversed size dimorphism. In at least one New World species, the Burrowing Owl, the male is slightly larger than the female, and males also are larger than females in the Rufous, Powerful and Barking Owls and the Papuan Hawk-owl.

More than 20 theories have been advanced to explain reversed sexual size dimorphism in birds. Several of them flow from the strict division of labour in owl breeding biology. For instance, because only females incubate the eggs and brood the young, selection could act to produce larger females that could brood more efficiently. In general, RSD seems to be higher in species that eat vertebrate prey, such as *Bubo*, *Strix* and *Aegolius*, and lower in insectivorous species such as the screech-owls and scops-owls of the genus *Otus*. E. Korpimäki has suggested that it is advantageous for female Boreal Owls to be large so that they can survive periods of food shortage, whereas the males, being small and agile, can hunt more efficiently and effectively. Although the argument for small males may hold, H. C. Mueller has stated that females of all sizes can simply increase their fat reserves to survive periods of food shortage. Moreover, R. P. and D. M. Gerhardt point out that the owl species with the highest known sexual dimorphism in size, the Mottled Owl, is not only insectivorous but also lives in tropical forest, where food shortages are probably rare or non-existent.

W. B. McGillivray's analysis of reversed sexual size dimorphism in owls led him to conclude that the phenomenon was unlikely to result from ecological forces such as differential foraging between the sexes. He pointed out, for instance, that the Snowy Owl and the Short-eared Owl have relatively similar foraging and migration strategies but strikingly different dimorphism indices. McGillivray also found no strong evidence of shape differences between males and females that would have resulted from selection for different foraging strategies. The maze of theories surrounding RSD is further complicated by the conflicting data that emerge when one considers different body-size variables such as mass, wing length, and the dimensions of various bones. Several investigators contend that wing length and body mass are poor variables to use, because the former can be difficult to measure and varies owing to feather wear, whereas the latter is highly variable among seasons. Moreover, mass data are often taken from museum specimens dominated by birds that have been found emaciated in winter, or are gathered from breeding studies, when female owls can be 50% heavier than at other times of the year.

After examining all of the current theories, Mueller felt that many factors could affect the amplitude of dimorphism, but that the only one that could explain the origin of the phenomenon was female dominance and the establishment of the pair-bond. This theory holds that dimorphism results from sexual selection in which females choose males that are smaller and, presumably, less aggressive. This is, of course, the opposite of what happens in the other form of sexual size dimorphism in birds such as grouse (Tetraonidae) and pheasants (Phasianidae), in which females apparently choose the larger, more dominant males.

Habitat

Strigids occupy virtually all of the world's major terrestrial habitats, being absent only from extremely high elevations and treeless portions of harsh deserts such as the Sahara. They occur on every continent except Antarctica, and one species, the Short-eared Owl, has colonized some of the most remote oceanic islands in the world. Still another, the Burrowing Owl, spends part of its life underground. By far the majority of species, how-

ever, roughly 95%, reside in forest of one kind or another. As is true for almost any species of bird, the chief factors that dictate habitat use by owls are food and nest-sites. The latter are especially critical for strigids, because they do not build their own nests, relying instead on natural sites or existing structures built by other bird species (see Breeding). Although basic information on habitat associations is known for many owls, studies of actual habitat use have been conducted on only a handful of species. Consequently, few details are available on how owls exploit the habitats they occupy, how and where they obtain food, and how habitat use varies seasonally.

Not surprisingly, the highest number of owl species occurs in tropical forest. Indeed, approximately 80% of the world's strigids can be found in the tropics: 28% in Central and South America, especially *Otus*, *Glaucidium* and *Strix*; 25% in Asia, represented by *Otus*, *Glaucidium*, *Bubo* and *Ketupa*; 19% in Africa, notably *Ptilopsis*, *Bubo* and *Scotopelia*; and 8% in Australasia, all *Ninox*. Within this belt of latitude, however, owls occupy a wide variety of wooded habitats that range from dense lowland jungle to second-growth forest, savanna, plantations and arid scrubland.

High-elevation cloudforest in the New World tropics supports a luxuriant growth of vegetation and a high diversity of owls. The steep, mountainous terrain characterized by this habitat can be of difficult access for humans, and can also be prone to natural habitat fragmentation. Thus, some of the species that are tied to cloudforest are known only from very small ranges. For example, the Bearded Screech-owl (*Otus barbarus*) inhabits a restricted zone of cloudforest in southern Mexico and northern Guatemala. Two recently described species, the Cinnamon Screech-owl and Hoy's Screech-owl, (*Otus hoyi*), are restricted to the Andes of, respectively, southern Ecuador to northern Peru and southern Bolivia to north-western Argentina. The newly described Cloudforest Pygmy-owl (*Glaucidium nubicola*) is known only from the west slope of the Andes in Colombia and Ecuador. Perhaps the most mysterious strigid of the South American cloudforest is the rare and distinctive Long-whiskered Owlet, which has so far been encountered only in a remote region of northern Peru.

Four screech-owls that inhabit South American cloudforest more or less replace each other along an elevational gradient. The most widespread of these, the Tawny-bellied Screech-owl,

Age-related plumage differences tend to be rather minor among most owls, and juveniles, once they have lost the last vestiges of down, are often extremely difficult to separate from adults of their species. There are, however, some exceptions, one of the most striking of which is shown by the aptly named Spectacled Owl. The juvenile lacks the adult's dark brown head and breast with distinctive pale "spectacles", instead having a pale, almost whitish head and body with a conspicuous dark heart-shaped "eye-mask". This species can take up to five years to reach full adult plumage.

Patricia Fogden]

occupies lowland rainforest across Amazonia but extends its range upwards on the eastern face of the northern Andes. In the Andes it is replaced in elevation by the Rufescent Screech-owl, which occupies a narrow band of cloudforest from Venezuela to Bolivia. Occurring higher still is the Cloudforest Screech-owl, known only from dense mountain forest in south-central Peru. Finally,

the White-throated Screech-owl (*Otus albogularis*) has a distribution very similar to that of the Rufescent Screech-owl, except that it occurs at higher elevations and occupies stunted alpine forest and forest edges, as well as cloudforest. Other cloudforest species that occur in much of the northern Andes are the Rufous-banded Owl and the Andean Pygmy-owl.

Dense lowland rainforest in the New World tropics supports a diverse suite of species that includes the Crested, Spectacled, Tawny-browed and Black-banded Owls. Also occurring in this habitat, but occupying a variety of forest types in addition to primary rainforest, are the Variable Screech-owl (*Otus atricapillus*), the Rusty-barred Owl (*Strix hylophila*), the Mottled and Black-and-white Owls, the Amazonian and Least Pygmy-owls and the Buff-fronted Owl. The Rufous-legged Owl and the closely related Chaco Owl inhabit dense subtropical and temperate forest in southern South America.

Extensive areas of rainforest are fast becoming rare in the Old World tropics, especially in South-east Asia and West Africa. Among the strigids largely confined to primary rainforest in Asia and western Indonesia are the White-fronted (*Otus sagittatus*) and Reddish Scops-owls (*Otus rufescens*), the Forest (*Bubo nipalensis*) and Barred Eagle-owls (*Bubo sumatranus*), and the Chestnut-backed Owlet (*Glaucidium castanonotum*). Similarly, the Ochre-bellied Hawk-owl (*Ninox ochracea*) is closely associated with rainforest in eastern Indonesia, as are the Jungle Hawk-owl (*Ninox theomacha*) and the Papuan Hawk-owl in New Guinea. In Africa, dense lowland rainforest occurs mostly in a band along the equator in the west-central part of the continent. Restricted to this endangered habitat are the Sandy Scops-owl (*Otus icterorhynchus*), the Maned Owl, Fraser's (*Bubo poensis*), Shelley's (*Bubo shelleyi*) and the Akun Eagle-owls (*Bubo leucostictus*), and the Red-chested (*Glaucidium tephronotum*), Sjöstedt's and the Albertine Owlets (*Glaucidium albertinum*). Little is known of the biology of most of these species owing to their patchy distribution and the difficulty of studying them in the dense forests they inhabit.

All four Australian strigids belong to the genus *Ninox*. The Rufous Owl is the second-largest member of *Ninox* and the least known of the four species. It occurs in three disjunct areas in northern Australia, in the lowlands of New Guinea, and on the Aru Islands. The two Queensland populations inhabit lush rain-

As it takes off from a post, a favourite lookout for many owl species, a Eurasian Eagle-owl reveals the long, feathered legs and toes typical of its genus. This species has a wide range in the Old World, extending right across Eurasia and into northern Africa. It occurs mostly in dry, rocky areas, forest and steppe, from lowlands to mountains, tending to avoid human contact.

[*Bubo bubo hispanus*, Torre Ponsa, Montgrí, Catalunya, Spain.
Photo: Ramon Mascort & Albert Burgas]

Although generally associated with forest and other types of woodland, the majority of owls by no means shun open spaces, especially if these provide a rich source of suitable food. Moreover, as demonstrated by this Eurasian Eagle-owl, even relatively secretive species will sometimes move from one favourable site to another by flying over open water, when they can then provide an unexpected sight for the vigilant observer.

Owls in general are skilled and adept flyers, whether in open habitats or in closed forest and dense woodland. Flight is their main method of locomotion when approaching and capturing prey. Medium-sized and large species such as this male Ural Owl, a bird which prefers old-growth coniferous forest and edges, but also inhabits deciduous woodland in the south of its range, progress with a series of moderately slow flaps followed by a glide on outstretched wings.

The smaller species, typified by the tiny Austral Pygmy-owl of rather open forest and open country with trees and bushes, have a basically similar mode of progression, but the wingbeats are much more rapid and the glides are performed with the wings held closed against the body; over longer distances, this produces an undulating flight, not unlike that of a small woodpecker (Picidae).

The eyes of owls are set well apart on the front of the face, which is very flat compared with that of most other avian families. This provides them with excellent depth of vision. Their eyes are not directed fully forwards, however, but diverge at an angle of approximately 50-55°, thus enhancing the total field of view. In order to increase the accuracy of depth perception provided by binocular vision, owls therefore bob the head and move it from side to side. This highly characteristic habit of strigids, frequently recorded in natural history films, enables them to measure distances with a remarkable degree of precision, an important advantage for open-country species such as the Short-eared Owl, which locate prey by sight as well as by sound.

[*Asio flammeus flammeus*, southern Alberta, Canada. Photo: D. Robert Franz/Planet Earth]

forest, whereas the population from the Northern Territory and adjacent Western Australia occurs in dense woodland bordering savanna. Wherever they occur in Australia, they have a penchant for living near watercourses. Although Rufous Owls are usually associated with lowland forest, a recent study by J. Kanowski showed that they are relatively common in highland forest at 800-1200 m in north-eastern Queensland. The aptly named Powerful Owl is the largest species of *Ninox* and occupies the most restricted range of the three better-known species in Australia. Powerful Owls occur in a narrow band along the Great Dividing Range in the south-eastern portion of the continent. The highest numbers are found on the coastal eastern side of the mountains, where they favour tall eucalypt forest on ridges and along valley bottoms. In undisturbed habitats, each pair requires 800-1000 ha of forest, and adjacent pairs may be separated by 5-20 km of unoccupied habitat. Territories are even larger in degraded habitats, and the birds are quite sensitive to habitat disturbance (see Status and Conservation). The medium-sized Barking Owl occurs in savanna, open woodland and forest edge in Australia and New Guinea. Its range in Australia forms a continuous ring extending around all but the southern and western edges of the continent, and includes a disjunct population south of Perth. The Southern Boobook is Australia's most abundant owl, occurring across the entire continent as well as in parts of New Guinea and the Lesser Sunda Islands. In his 1968 book *Nightwatchmen of Bush and Plain*, D. Fleay states that "Without a doubt, Australia's population of Boobook Owls runs into the millions for almost anywhere one camps at night...the leisurely sing-song 'morepork' call is as typical as the very gum trees." Southern Boobooks occupy virtually all major habitats within their vast range, including dense rainforest, eucalypt forest, savanna, farmland, suburbs and even desert. Although this species seldom occurs far from trees, in the more arid parts of its range it roosts in caves and beneath overhanging ledges on cliffs. In contrast to the other *Ninox* in Australia, Southern Boobooks feed mostly on insects. The diversity

of habitats in which they forage is reflected in the various substrates where they obtain their prey, which include the ground, tree trunks and the forest canopy, and they even capture prey in mid-air.

Unlike some sea-eagles (*Haliaeetus*) and coastal populations of Ospreys (*Pandion haliaetus*), no owl is restricted to salt water, although Blakiston's Eagle-owls and Northern Saw-whet Owls may forage in the intertidal zone. Owls in the genera *Ketupa* and *Scotopelia* feed mainly on aquatic organisms and seldom occur far from fresh water. The Brown Fish-owl inhabits a wide range of forest habitats near slow-moving streams, occurring from near sea-level on the southern coast of Asia to mountain forest in the interior of India and Pakistan. The Tawny Fish-owl is restricted to dense areas of forest along mountain streams, and it seems to prefer faster-moving water than the previous species. The Buffy Fish-owl is partial to coastal forest and mangroves in South-east Asia and adjacent Indonesia.

Blakiston's Eagle-owl, which is placed in the fish-owl genus *Ketupa* by some authorities, is the only piscivorous owl with a range that extends far beyond the tropics. Confined to the Russian Far East and Japan, it prefers dense, undisturbed forest near lakes or fast-flowing streams, and its numbers have declined in areas where this habitat has been destroyed (see Status and Conservation). The home range of a radio-tagged adult female on Hokkaido averaged about 3 km² during spring. Most of the radio locations occurred in mixed deciduous-coniferous forest, and the owl was never found more than 465 m from water.

All three species of fishing-owl inhabit riverine forest in Africa. Pel's Fishing-owl (*Scotopelia peli*) is the most widespread member of the genus and is patchily distributed throughout much of sub-Saharan Africa. Nowhere common, it occupies a greater range of elevations than the other fishing-owls. The Vermiculated Fishing-owl (*Scotopelia bowieri*) is relatively common along large rivers in the Congo basin, whereas the closely related Rufous Fishing-owl (*Scotopelia ussheri*) is quite rare and is known

only from Upper Guinea lowland forest and coastal mangroves from Guinea to Nigeria. The only other owls consistently associated with mangrove forest, at least in parts of their range, are the Pacific Screech-owl (*Otus cooperi*) of western Central America, the Palau Owl, and the Brown Hawk-owl of Asia and Indonesia. The last two species occupy a variety of forest types, in addition to mangrove, and the Palau Owl is the only living strigid that frequents Pacific atolls.

The Puerto Rican Screech-owl (*Otus nudipes*) is common in forested areas throughout the island of Puerto Rico and is rare on several of the Virgin Islands. Its distribution is thought to be limited by the availability of suitable forest habitat, and it has disappeared from at least two small islands in the Caribbean. K. L. Pardieck and associates recently assessed the influence of habitat fragmentation on this species by broadcasting vocalizations along roadsides in Puerto Rico. Owl responses to playbacks were quite high, averaging 0.96 to 1.1 responses per survey point, in both the unfragmented forest tracts (95% forest cover) and the fragmented tracts (36% forest). The results suggested that Puerto Rican Screech-owls can be reintroduced to islands where they have been extirpated, provided that suitable nesting cavities and food are available.

In contrast to many of the tropical species, most of the strigids that inhabit temperate forest in the Northern Hemisphere tend to be widespread, including several Holarctic species. The Eastern Screech-owl is a common inhabitant of deciduous forest throughout the eastern USA, and it is replaced in the western USA by the Western Screech-owl, which inhabits deciduous riparian forest. In parallel fashion, the Eurasian and Oriental Scops-owls replace one another in deciduous and mixed woodland from west to east across Eurasia. Likewise, the Barred Owl is quite common in North America and has an equally common counterpart in Eurasia, the Tawny Owl, both species frequenting deciduous, coniferous and mixed woodland. The Spotted Owl of the Pacific North-west of North America and the Ural Owl of northern Eurasia are tied to old-growth coniferous forest in much of their ranges; the southern race of the Spotted Owl occurs in wooded canyons amid arid habitats, whereas the Ural Owl inhabits deciduous woods in the southern part of its range. The Great Grey Owl, the

Northern Hawk-owl and the Boreal Owl occupy a band of boreal-forest habitat across Canada, Alaska and Eurasia. In the USA, Boreal Owls extend their range southwards along the Rocky Mountains, where they are restricted to spruce-fir forest at high elevations. Great Grey Owls extend south of the taiga into the Rocky Mountains and the Sierra Nevada range, where they occupy mixed forest of conifers and aspens (*Populus tremuloides*).

The Great Horned Owl probably occupies a wider range of habitats than any other species of owl. Occurring from the limits of the tree-line in Alaska and Canada south to southern parts of South America, Great Horned Owls are equally at home in stunted boreal forest, old-growth conifers, shrubland, grassland and treeless deserts. Indeed, one would be hard pressed to find a habitat in which they do not occur, especially in North America. The Great Horned Owl's success results in part from three factors. First, its huge size enables it to exploit a great diversity of prey types (see Food and Feeding); second, and related to the first factor, throughout most of its range it has no competitors of similar size and ferocity; and, last, it will nest almost anywhere where it can find suitable concealment, its nest-sites including cavities in cliffs or trees, broken-top snags, ledges on old buildings, stick nests built by hawks or corvids, and the ground. The breadth of habitats occupied by the Eurasian Eagle-owl is nearly as impressive. This species occurs across Eurasia, inhabiting mountain and lowland forest, steppe, farmland and rocky deserts. It tends to occur at lower densities than the Great Horned Owl and to shun areas frequented by humans, perhaps because it has experienced a longer period of human persecution than has its New World relative. Overall, the two species are similar in their use of habitat, and they play comparable roles in their respective ecological communities.

The arid thorn-scrub of sub-Saharan Africa supports a variety of owls that includes the African Scops-owl (*Otus senegalensis*), the Northern White-faced Owl, the Greyish and Verreaux's Eagle-owls (*Bubo lacteus*) and the Pearl-spotted Owlet. White-browed Hawk-owls occupy similar habitat in Madagascar. J. Mendelsohn's study of six sympatric owls, two tytonids and four strigids, in the Transvaal of South Africa revealed the influence of nest-sites and hunting behaviour on habitat

All owls have an extremely flexible neck, an ability necessitated by the fact that the eyes, unlike those of humans, are fixed in their orbits and can be moved by no more than 1° of arc; the owl can turn its head 270° to see sideways and behind it. In tandem with this, an intriguing plumage pattern shown by all the New World *Glaucidium* species, as well as some of the Old World ones, is the pair of "false eyes" on the back of the head. As demonstrated by this Least Pygmy-owl, these dark, normally pale-bordered patches bear a remarkable resemblance to an owl face and are thought to help these diurnal hunters to escape the attention of larger predators and smaller mobbing birds, by giving the impression that the owl is always watching them.

The Strigidae family shows its greatest diversification in forested habitats of various types, which harbour as many as 95% of all the world's species of owl. Tropical forest is by far the most important, holding some 80% of the family's members. A significant number of these are more or less restricted to primary rainforest, as, for instance, is the Barred Eagle-owl of South-east Asia and the Greater Sunda, where this complex habitat is becoming increasingly fragmented and degraded.

[*Bubo sumatranus sumatranus*, Pasoh Forest Reserve, Peninsular Malaysia. Photo: Frank Lambert]

use in disturbed thorn-scrub. The study area of 6900 ha was composed of 72% cultivated land, 17% acacia woodland, 5% grassland, 5% roads and 1% farmyards, and was highly altered by humans and livestock. Among the strigids, Spotted Eagle-owls and Pearl-spotted Owlets tended to nest and roost in exotic trees near homesteads, whereas Southern White-faced Owls were associated with native acacias. Marsh Owls, on the other hand, nested on the ground beneath isolated clumps of grass or small shrubs, and roosted communally in open acacia woodland. Because they hunted exclusively from perches, Southern White-faced Owls, Spotted Eagle-owls and Pearl-spotted Owlets were absent from treeless habitats, whereas Marsh Owls were less restricted in their use of hunting habitats. A high density of prey facilitated the co-existence of many individual owls in the area.

The arid scrubland of South America is inhabited by the race *pacificus* of the Peruvian Screech-owl and by the Austral and the Ferruginous Pygmy-owls. The last two species also occur in habitats other than scrub, including open deciduous forest and even city parks. Indeed, the Ferruginous Pygmy-owl has the largest geographical range of any *Glaucidium* in the New World, occupying deserts, savanna and semi-arid woodland from South America north into Texas and Arizona in the USA.

Only six strigids can truly be called non-forest species. These are the Snowy, Hume's, Little, Burrowing, Short-eared and Marsh Owls. The Snowy Owl breeds in Arctic tundra characterized by rolling terrain with high spots or rises that are used for nest-sites and as vantage points. Hume's Owl is a "wood-owl" that does not live in woodland; it frequents desert gorges, canyons and palm groves, and often occurs near water. The Little Owl inhabits open country throughout the middle latitudes of the Palearctic, favouring shrub-steppe and semi-desert. It is thought that it did not colonize central and western Europe until lowland forest areas were cleared in the Middle Ages. This species may have occurred in Britain during the Pleistocene; it was re-established there in the late nineteenth century after several unsuccessful attempts at reintroduction, and there may currently be as many as 10,000 pairs in Britain, where it frequents farmland and pastures and is often associated with human habi-

tation. In western North America, the Burrowing Owl occurs in grassland, shrubland and deserts, so long as these habitats contain suitable burrows for nest-sites (see Breeding); it has also adapted to civilization, and routinely nests at such places as golf courses, airports and college campuses and in other open habitats created by humans; in South America, it occupies savanna and alpine grassland, as well as various desert-like habitats. The Short-eared Owl tends to be nomadic, wandering from place to place in search of concentrations of prey. Regardless of the time of year, and throughout its vast geographical range, this owl inhabits open country of one sort or another; grassland, marshes, shrubland and tundra are used for breeding, provided that adequate cover, usually in the form of tall grasses, exists to conceal the female on the nest. The Short-eared Owl has colonized remote oceanic outposts such as the Hawaiian and Galapagos Archipelagos; in Hawaii it occupies open shrubland and pastures, and in the Galapagos it occurs in upland *pampas* but also forages at seabird colonies along the coast. The Marsh Owl is more or less an ecological equivalent of the Short-eared Owl in Africa, where it inhabits marshes, grassland and savanna south of the Sahara Desert and in Madagascar. Like the Short-eared, the Marsh Owl tends to be nomadic in response to fluctuating prey numbers.

Two species occupy a mix of open and sparsely forested habitats. The Elf Owl frequents deserts, especially cactus desert, and other treeless habitats in the North American South-west, but also occurs in riparian woodland and open forest on slopes above deserts. The Northern Long-eared Owl inhabits much the same range as the Short-eared Owl, but does not occur in South America or on oceanic islands. In western North America, the Northern Long-eared is most abundant in desert shrubland and grassland, where it nests and roosts in dense thickets of deciduous vegetation adjacent to open areas, using the latter for hunting. Especially in eastern North America, the Northern Long-eared Owl roosts in conifer groves during the winter, and it occasionally nests in open conifer forest throughout its North American breeding range. In Eurasia, this species occupies wooded patches in a variety of open and semi-open habitats,

Owls range across a broad spectrum of climatic regions, from the very cold

Arctic to the hot, arid deserts of the tropics and subtropics. This Northern Hawk-owl gained some respite from the severity of the far northern winter by taking up temporary residence in the photographer's garden, where it remained for four months, presumably taking advantage of an improved or more easily accessible food supply.

At the other extreme, those species inhabiting the vast arid wildernesses of the desert would seem unlikely to find similar human assistance.

The race desertorum of the Pharaoh Eagle-owl, here photographed in the harsh desertic conditions of the southern edge of the Sahara, has to eke out an existence by catching any small rodents that it comes across.

Nevertheless, in these two contrasting environments, the owls manage to survive well, being supremely adapted to the respective habitats in which they live.

While Hume's Owl is frequently associated with dry, rocky desert wadis and gorges and similar open habitats, it can often be seen also in and around palm groves. This attractive owl occurs near freshwater springs, too, and even on the edge of human settlements, but tends in general to avoid human contact. In sharp contrast to its darker northern relative the Tawny Owl (*Strix aluco*), however, which is strictly a forest and woodland bird, Hume's Owl is one of the mere half-dozen strigids that can be accurately described as a non-forest species.

[*Strix butleri*, near Dead Sea, Israel.

and is perhaps more of a forest owl than in North America; outside the breeding season, however, it can also be found in open, treeless country such as moorland and steppe.

Most strigids are non-migratory, but those that do migrate (see Movements) tend to winter in habitats that have the same general structure as those used during the breeding season. For example, Eurasian Scops-owls breed in open forest in western Europe and migrate to central Africa, where they winter in open forest and savanna. In the northern Rocky Mountains, Flammulated Owls migrate from their breeding sites in montane pine forest, presumably to winter in the extensive areas of pine forest in Mexico. Snowy Owls that move south for the winter occupy grassland, farmland, marshes and dunes, habitats that are structurally similar to tundra. Burrowing Owls migrate from the northern part of their range in western North America to winter in the Southern Great Plains, where they exploit habitats that are very similar to those occupied on the breeding grounds.

Some owls do, however, undergo seasonal shifts in habitat. Several Northern Long-eared Owls radio-tagged by H. Ulmschneider in the shrub-steppe desert of the Snake River Birds of Prey Area, in south-western Idaho, left their breeding territories soon after the young fledged to spend the summer in open conifer forest in the foothills north of the Snake River Plain. In the same study area, in years when small mammals are abundant, Northern Saw-whet Owls, which normally nest in moist coniferous forest, breed in nestboxes in deciduous riparian thickets in the desert. Before these nestboxes were available, this species was not known to breed in shrub-steppe deserts, although it was relatively common there during migration and in winter.

Owls generally are not considered to be birds of high mountains, and most species live at elevations between sea-level and 2000 m. Several species ascend to 2500 m, however, and a few can be found at much higher elevations than that. For example, Eurasian Eagle-owls inhabit pastures at up to 4700 m in Tibet, Andean Pygmy-owls and Rufous-banded Owls occupy forest at 3700 m or above in the Andes, Burrowing Owls live on alpine plateaux above 4000 m in South America, and African Long-eared Owls have been observed at 3500 m in Kenya and at nearly 4000 m in Ethiopia.

General Habits

Nocturnal owls spend the daylight hours perched quietly in concealed sites, such as amid the foliage and branches of a tree, in a recess on a cliff, or inside a cavity. Cryptic plumage serves to hide owls from daytime predators and mobbers, not to conceal them from potential prey. Many species are considered to be "tame" because they often allow close approach before taking flight. It is true that some owls are indeed remarkably tame, such as those Arctic and boreal species that seldom see human beings until a crash in prey numbers drives them south, or to lower elevations, for the winter, when they may end up perched along a busy road, seemingly oblivious to the cars and the people passing below them. For owls that routinely encounter humans, however, so-called tameness is a part of their behavioural repertoire designed to avoid detection.

Take, for example, the typical reaction of a Northern Long-eared Owl to a human being, a response that would apply equally well to other similar-sized species. In the absence of disturbance, the owl perches in a "relaxed" position on a limb, concealed from view by the trunk and surrounding branches. At the approach of a human, the owl stretches out vertically and draws its contour feathers against its body in what can be described only as an attempt to appear as thin as possible; the eyes are partially open, and the ear-tufts are erect. If the person does not make eye contact with the owl, the owl will retain its position and posture as the intruder walks past it, sometimes as close as half a metre. If eye contact occurs, however, the owl ceases its "concealing" posture, opens its eyes wide, and flies away. It may fly to several different perches if the human being continues pursuit, but it will not adopt the concealing pose again, nor will it remain perched as the human approaches. On the basis of this scenario, one may infer that owls routinely respond to a terrestrial predator by remaining still if the predator passes by without knowing that the owl is present.

Smaller species, such as the Eurasian and Northern Pygmy-owls, the Boreal Owl and the Northern Saw-whet Owl, exhibit a variation of the aforementioned pose. In this case, the eyes are suddenly opened wide, the whitish feathers between the eyes are

Of all the world's owls, the Great Horned Owl must surely occupy the widest range of habitats. It occurs throughout most of the Americas, from the limits of the tree-line in the north Nearctic south to the southern parts of South America. Within many parts of this huge range it is likely to be found in forested areas of most types, but it can also be met with in grassland, shrubland and entirely treeless habitats. It is equally at home in rocky areas and places with steep gorges, or around the stone walls of canyons, as it is in the comparatively "softer" habitat of old-growth conifer stands. This highly successful species has been able to exploit virtually all available habitats because it has no major competitors, it takes a very wide range of prey, and it will accept a considerably broad spectrum of nesting sites, including cliff cavities and suitable ledges on rock faces and old buildings, so long as these provide sufficient concealment. Unlike its Old World counterpart, the Eurasian Eagle-owl (*Bubo bubo*), the Great Horned Owl does not shun areas frequented by human beings; as a consequence, it is rather better known to many people than is the latter species.

erected, the crown feathers above the eyes are raised to resemble "ear-tufts", and one wing is elevated to the level of the bill like a vampire raising its cape to its face! Although this posture is termed a "concealing pose" by some authors, S. Bondrup-Nielsen pointed out that this behaviour is revealing rather than concealing, because the abrupt movements made while opening the eyes and raising the wing, and the accentuation of the white patches around the eyes, would be likely to draw the attention of a predator. Bondrup-Nielsen suggested that the pose be termed an "erect posture" to avoid confusion with true concealing behaviour. Subsequent study of a Northern Saw-whet Owl by S. G. Sealy and K. A. Hobson supported the revealing function of the erect posture, and these researchers suggested that the posture is a fright response to disturbance, or that it perhaps serves to threaten a potential predator.

Mobbing is a type of anti-predator behaviour in which individuals approach a potential enemy and perform conspicuous calls and visual displays; the predator may or may not be struck during the mobbing event. Owls are popular targets for mobbing birds, but most studies of mobbing have focused on the mobbers rather than the predators. One exception is the recent study by C. R. Pavey and A. K. Smyth on how mobbing influenced the roosting behaviour of a family of Powerful Owls. Pavey and Smith observed 35 cases of mobbing involving seven species of mobbers; ten mobbing bouts were directed at the male owl, 17 at the female, and eight against the three young owls. Mobbers ranged in size from the Grey Fantail (*Rhipidura fuliginosa*) of 8 g to the Pied Currawong (*Strepera graculina*) of 320 g, which translated to 4-26% of the mass range of the owls. Of the 33 mobbings observed in sufficient detail, seven produced no apparent response by the owl, 19 elicited a vocal response, and in seven cases the owl moved its perch, sometimes with the mobber in hot pursuit. Half of the 229 recorded owl roosting sites were in rainforest and half were in open forest, even though rainforest made up only 12% of the study area. Mobbing occurred more frequently when the owls roosted in open forest than when they used rainforest, with 77% of mobbing events in the former and 23% in the latter. This suggests that the owls selectively roosted in rainforest in order to avoid being mobbed.

Many owls are aggressive near their nests, especially after the chicks have hatched. Nesting Great Grey Owls sometimes attack black bears (*Ursus americanus*), and they routinely drive off Northern Goshawks (*Accipiter gentilis*) that enter the nest area. In addition, larger species such as the Great Horned Owl, the Eurasian and Verreaux's Eagle-owls, and the Snowy, Ural and Great Grey Owls often strike human beings. Indeed, the Ural Owl in northern Scandinavia is renowned for its readiness to attack anybody who is rash enough to approach its nest and young, and it will go for the eyes of the intruder; despite its "good looks", it can be a very dangerous bird if approached at the wrong time of the year! Medium-sized species such as the Tawny Owl, African Wood-owl, Northern Hawk-owl and Northern Long-eared Owl, and even small species such as the Eastern Screech-owl and Eurasian Pygmy-owl, also strike humans on occasion. Species not known to strike human beings will nonetheless swoop at them when defending the nest. It seems likely that these species would vigorously attack smaller predators that are less formidable than humans. In many strigid species, both sexes defend the nest, but the female is usually the more aggressive sex (see Breeding).

In a typical threat posture, an owl crouches with its head lowered, its wings drooped, and the body feathers ruffled so as to increase its apparent size. The adults and young of many species also adopt a spread-wing posture in which the wings are turned vertically and fanned out above and to the sides of the head, again with the effect of increasing the apparent size of the individual. Most species utter a variety of vocalizations and clack their bills during these aggressive displays. The wing-clapping display of courting Northern Long-eared, Short-eared and Marsh Owls (see Breeding) is used also in aggressive interactions with predators and conspecifics.

A suitable roosting site satisfies several different functions, including concealment from predators and protection from harsh environmental conditions. Many cavity-nesting species also roost in cavities, but important exceptions exist. G. A. Sonerud's study of three hole-nesting owl species in Norway determined how the risk of nest predation influences behaviour during incubation, and his results can be extended to roosting behaviour. Nesting

Since they feed largely on a diet of aquatic organisms, the Asian fish-owls of the genus *Ketupa* require the proximity of fresh water. The Brown Fish-owl is a typical example. This magnificent species inhabits various types of forest, especially dry forest, with slow-flowing streams; in such places it prefers large, old trees, often on steep banks, from where it can drop down to catch fish and other items.

[*Ketupa zeylonensis* leschenault, Ranthambore National Park, India. Photo: Anup & Manoj Shah/Animals Animals]

A once familiar sight in parts of western North America is that of a Burrowing Owl perched on a lookout in open grassland and desert country. This species, which has declined greatly in the north of its range, remains a reasonably common bird in South America, where it occupies similar habitats and is a characteristic bird of savanna, alpine grassland and desert-like areas with short, rather sparse vegetation. It can often be seen keeping watch from an elevated site such as a termite mound, as is this individual, photographed in the cerrado region of south-central Brazil. For nesting, these owls require underground burrows, especially those dug by prairie-dogs (*Cynomys*), so the substrate of their habitat needs to be reasonably soft. With the widespread loss of natural grassland, particularly in the USA, Burrowing Owls have adapted to man-altered environments and now frequent such places as grassy airfields, golf courses and college campuses.

cavities required by Northern Hawk-owls and Boreal Owls were large enough for Eurasian pine martens (*Martes martes*) to enter, but those used by Eurasian Pygmy-owls were not. When Sonerud scratched on the trunks of nest trees to simulate an approaching predator, incubating females of the first two species appeared at the nest-hole immediately, ready to take flight, whereas female Eurasian Pygmy-owls did not. The results indicate that vulnerability to predation influences the behavioural responses of these species during the incubation period.

Studies in North America and Eurasia have shown that male Northern Hawk-owls and Boreal Owls hardly ever roost in cavities, and that females use cavities only during the incubation and brood-rearing stages. Similarly, Flammulated Owls and Northern Saw-whet Owls often nest in habitats used by American pine martens (*Martes americana*), but males do not roost in cavities and females use them only during the nesting season. Although Flammulated Owls can fit into holes that are too small for martens to enter, they often use Pileated Woodpecker (*Dryocopus pileatus*) cavities that are large enough to admit martens. In contrast, Western and Eastern Screech-owls live in habitats where martens typically do not occur, and males and females of both species routinely roost in cavities throughout much of the year. In agreement with Sonerud's Norwegian results, experiments have revealed that female Flammulated and Northern Saw-whet Owls appear at the cavity entrance immediately if someone scratches the base of the nest tree, whereas incubating and roosting screech-owls of both species seldom react to such disturbance.

Independent of predator avoidance, an obvious benefit of roosting in a cavity is the favourable micro-climate it provides. Western Screech-owls in south-western Idaho almost never roost in nestboxes during the hot summer months, but use them regularly from September through to March. Similarly, Eastern Screech-owls in central Texas show a preference for roosting in boxes or natural cavities during the winter and spring months, but not during summer. Non-enclosed roost-sites may function to provide a cool micro-climate. During the heat of the summer, Spotted Owls in California select shaded roosts that are up to 6°C cooler than exposed sites; moreover, they switch roost-sites during the day in response to increases in ambient temperature and exposure to direct sunlight.

Body temperatures of strigids generally range between 38°C and 41°C. Compared with most other groups of birds, owls tend to have a lower basal metabolic rate, less variation in the daily cycle of body temperature, and denser plumage. On balance, they have more trouble keeping cool than keeping warm. Indeed, J. D. Ligon showed that body temperatures of 42.3 to 44.3°C are lethal to Elf Owls and Northern Saw-whet Owls in as little as 10-20 minutes. As temperature increases beyond the upper limit of the thermoneutral zone, owls respond by reducing their activity, compressing their contour

Old trees and dead wood are important elements of the forest ecosystem, and therefore in the habitat of most forest-dwelling owls. Strigids do not build their own nests, but in most cases rely instead on the presence of natural cavities or of holes excavated by other birds, these hollows being found almost exclusively in old or dead wood. It is consequently essential that sufficient old timber remains to supply suitable sites for nesting and roosting by such species as the White-browed Hawk-owl.

[*Ninox supercilialis*, Berenty Private Reserve, Madagascar.
Photo: Jordi Sargatal/Lynx Edicions]

One of the ways in which the numerous strigids inhabiting forest avoid direct competition is by exploiting different strata of the habitat, or by hunting at different times of the day. The Collared Owllet uses open edges and scrub, where it tends to operate at lower levels; it is active at all hours, frequently foraging during daylight. This individual was photographed in the middle of the afternoon, at a perch about 4 m above ground. The comparatively long tail of this genus is also shown to advantage here.

[*Glaucidium brodiei*, brodiei, Khao Yai National Park, Thailand.
Photo: Bernard Van Elegem]

The typical threat posture adopted by many strigids is designed to make the owl appear bigger than it really is, and this applies even to the large species such as the Spotted Eagle-owl. The owl assumes a crouched stance, with head lowered, wings drooped and feathers ruffled, thereby increasing its apparent size quite considerably. At times it may raise the wings and turn them forwards to face the source of the danger, making intermittent lunging movements.

[*Bubo africanus africanus*,
Helderberg Nature
Reserve, South Africa.
Photo: Peter Steyn/Ardea]

feathers against the body, which reduces insulation, and holding their wings out from the body. If heat stress continues, owls use evaporative cooling by panting and gular-fluttering, the latter being accomplished by rapid vibration of the hyoid apparatus in the throat. Rates of gular-fluttering under heat stress were found to be 215-540 flutters per minute for Western Screech-owls, 176-523 for Elf Owls, 150-386 for Whiskered Screech-owls (*Otus trichopsis*), and 109-435 for Northern Saw-whet Owls. Panting rates for Whiskered Screech-owls and Elf Owls were 68-128 and 135-160, respectively.

Although all strigids are nocturnal to some extent, activity times vary considerably, both within and among species. By and large, species in the genera *Otus*, *Bubo*, *Strix*, *Jubula*, *Lophotrix*, *Aegolius*, *Ninox*, *Pseudoscops* and *Nesasio* are nocturnal. Eurasian Scops-owls and Eastern Screech-owls may be crepuscular or occasionally diurnal, especially during the breeding season, and Pallid Scops-owls (*Otus brucei*) have also been observed hunting by day. Spotted and Dusky Eagle-owls (*Bubo coromandus*) are crepuscular-diurnal, and Great Horned Owls and Verreaux's and Rock Eagle-owls will kill prey animals that wander under their daytime roosts. Among species of *Strix*, Spotted and Great Grey Owls hunt during the day when provisioning their young, and the latter species is also partly diurnal in winter. The four species of *Athene* are mostly nocturnal, but in much of their range Little Owls are active at any hour of the day, especially at twilight, and have been seen feeding young during the day in Morocco and Spain. Burrowing Owls commonly perch outside their burrows during the day, and for many years biologists thought that they were diurnal; night-time observations based on radio-telemetry and night-vision scopes, however, have proven that the birds are decidedly nocturnal hunters. Five of the seven species of *Asio* are nocturnal, but two, the Short-eared and Marsh Owls, hunt by day and night throughout the year. Boreal Owls and Northern Long-eared Owls are nocturnal except at the northern edge of their ranges, where they have no option but to hunt in daylight during the summer. Similarly, Snowy Owls and North-

ern Hawk-owls have to forage in the 24-hour daylight of the Arctic summer, but they hunt during the day and night in winter.

In many parts of the world, an owl seen hunting during the day is likely to be a pygmy-owl or owlet, and the genus includes some of the least nocturnal of the strigids. Indeed, on every continent in which they occur, at least three species of *Glaucidium* are conspicuous daytime hunters: the Eurasian Pygmy-owl, Collared Owlet (*Glaucidium brodiei*), Asian Barred Owlet and Jungle Owlet (*Glaucidium radiatum*) in Eurasia; the Pearl-spotted, Red-chested and African Barred Owlets in Africa; the Andean, Least and Austral Pygmy-owls in South America; and the Northern, Mountain and Ferruginous Pygmy-owls in North America.

Several nocturnal species have been subjected to all-night observations in an attempt to determine the temporal distribution of their foraging activity. A Flammulated Owl nest monitored in Idaho revealed that foraging activity began 10-30 minutes after sunset and continued until an hour before sunrise; activity peaked early in the evening and again just before sunrise, and there was no evidence that the owls foraged during the day. Four Tawny Fish-owls radio-tagged in Taiwan returned to their day roosts an average of 8-2 minutes before sunrise and left the roosts to resume foraging an average of 5-8 minutes before sunset; the owls were active throughout the night, but foraging activity peaked in the first hour after sunset. Similarly, radio-tagged Tawny Owls foraged throughout the night in Britain, but their activity was highest in the first hour or two after dusk. Other studies have shown that Tawny Owls occasionally hunt in daylight, especially when provisioning their young.

Radio-tagged Northern Long-eared Owls tracked in southeastern Idaho during the breeding season were active only at night. Presumed hunting activity was lowest in the first two hours after dusk and in the last hour before sunrise, and such weather factors as wind speed, precipitation and cloud cover had little effect on activity. Four more radio-tagged Northern Long-eared Owls, tracked during autumn and winter in the Netherlands, reduced their flight activity during periods of sleet. Independent

The owls are recognized as serious predators by all other bird species. As a result, they are subjected to constant attacks at all times of the year. Even owls as big as a female Snowy Owl are not immune from such attacks. On their breeding grounds in the Arctic, these huge birds are continually harried by other breeding birds, notably Long-tailed Skuas (*Stercorarius longicaudus*), notorious mobbers of all predators, including humans. Despite being dive-bombed, and even struck, by the skuas, the owl appears unworried by such harassment.

of weather conditions, flight activity peaked five to six times each night, perhaps reflecting the cycle of above-ground activity by voles. Roughly half of the foraging flights lasted less than five minutes, and only 10% of the flights exceeded ten minutes. The owls spent a median of 158 minutes in flight per night, which translated to about 20% of the time that they were active.

Unmarked Snowy Owls observed from December to February in Alberta, Canada, spent 98% of the daylight hours perched. Their hunting activity, in the form of perch changes and flights, peaked just after sunrise and just before sunset, and most attempts at prey capture occurred in the late afternoon. Because the observed rates of prey capture failed to balance the estimated daily energy budget, the researchers assumed that the owls carried out a considerable amount of hunting at night.

Most owls are solitary or occur in mated pairs. Non-migratory cavity-nesters tend to be highly territorial all year round, in order to maintain possession of scarce nesting sites. In species with permanent pair-bonds, both sexes vocalize to advertise their presence and keep out conspecifics. When referring to data on spatial use, it is important to keep in mind the distinction between a "home range" and a "territory", the former being the total area occupied by an individual or pair, and the latter being the area that is defended against conspecifics. Often, researchers who follow radio-tagged individuals are able to estimate home-range size but cannot say for certain how large an area is defended, especially if "territories" are not contiguous among adjacent breeding pairs.

Eurasian Scops-owls, which are almost wholly migratory in most of their range, apparently defend only a small territory around the nest; up to five nests have been reported in an area of only 0.6 ha, with the closest nests only 10 m apart! Home-range size varies within and among species and tends to increase with increasing body size. Accordingly, average home-range sizes of five non-migratory species in Europe, in increasing order of body size, are: 0.4-1.25 km² for Eurasian Pygmy-owls (50-80 g); 0.3-0.4 km² for Little Owls (150-200 g); 0.2-0.6 km² for Tawny Owls

(400-600 g); 4-5 km² for Ural Owls (600-1200 g); and 12-20 km² for Eurasian Eagle-owls (1500-4000 g). The relatively large home range of Eurasian Pygmy-owls perhaps reflects the preponderance of birds in their diet. Indeed, home-range size generally decreases as prey density increases. For example, breeding Snowy Owls defend 1-4 km² of tundra during high lemming years and 8-10 km² during lows in the lemming cycle. In an especially poor lemming year, a non-breeding pair may occupy a home range of 20 km². Similarly, the average territory size of Short-eared Owls over a three-year period in Scotland varied from 42 ha to 112 ha and was negatively correlated with vole abundance. Habitat characteristics may also influence territory size, independent of food availability. For instance, the territory size of Tawny Owls is smaller in woodland than in more open habitats, and the amount of woodland within a territory is negatively correlated with territory size.

Using radio-telemetry in combination with playback of vocalizations, P. Finck determined how average territory size varied throughout the year in a population of Little Owls in Germany. The largest territories, covering 28.1 ha, were defended during the courtship period in March and April, and males decreased the size of their territories to 12.6 ha during brood-rearing in May and June. Territories were smallest, at only 1.6 ha, in late summer, when broods were out of the nest but still being fed by their parents. Territory size increased to 9.5 ha during September and October, which corresponded to the post-fledging dispersal period, and increased further from November to February, when it extended over 19.8 ha. Despite the increase in defended area from autumn to winter, response to playbacks indicated that males were less aggressive in winter than during the spring courtship period. Aggressive behaviour ceased on days with cold temperatures and snow cover, suggesting that, in terms of energy expenditure, foraging then took precedence over territorial behaviour.

Only four species of strigids can genuinely be considered to be social. These are the Burrowing, Northern Long-eared, Short-

eared and Marsh Owls. No species, however, is truly colonial. Burrowing Owls sometimes nest in loose colonies, with densities of active burrows approaching 16 per ha in the best of conditions. Nearest-neighbour distances in these situations may be as little as 14 m. The owls do not seem to defend territories for hunting or nesting, and overt aggression is seldom observed except in extreme cases when an individual disturbed by humans attempts to enter a neighbour's burrow. Northern Long-eared Owls also are facultatively colonial, with nesting aggregations occurring in isolated tree groves during years of abundant prey. In Israel, as many as twelve nests have been recorded in a colony, with inter-nest distances of no more than 10 m; in the western USA, six Northern Long-eared Owl nests may be active simultaneously in an area of less than 2 ha, the closest nests being only 14 m apart. Like Burrowing Owls, Northern Long-eared Owls do not defend a nesting territory, and radio-telemetry studies have shown that close-nesting pairs overlap widely in their use of hunting areas. Marsh Owls in Africa also nest in loose aggregations, although not to the same extent as Northern Long-eared Owls, the closest nests being about 75 m apart. Unlike the Northern Long-eared, Marsh Owls are known to defend territories against conspecifics. Also worthy of mention with regard to sociality are Great Grey Owls, which are sometimes tolerant of conspecifics outside the pair-bond: as many as four adult males and their fledged young have been observed hunting in the same field in Manitoba, Canada. The extent to which Great Grey Owls defend hunting territories against members of their own species is unknown.

Burrowing Owls and Northern Long-eared Owls are not colonial nesters in the true sense, because they do not congregate together in the way that obligate colony nesters such as, for example, many seabirds, herons and Arctic geese do. For either of these two owl species, one gets the impression that adjacent pairs could be removed from a nesting aggregation without any effect on the remaining pair or pairs, which is in marked contrast to a colonial species, which settles preferentially near conspecifics. The adaptive significance, if any, of semi-colonial nesting in Burrowing and Northern Long-eared Owls is not known. Quite possibly, the birds may be drawn to areas with suitable nesting sites and adequate food resources, where they congregate passively because they are not territorial. Close-nesting individuals of both species do, however, participate in group defence against predators, and the success in deterring a formidable predator undoubtedly is higher for a group than for an individual, raising the possibility that group-nesting is adaptive.

Sociality outside the breeding season is well developed in Northern Long-eared, Short-eared and Marsh Owls, each of which roosts communally in winter. Such roosts often contain more than 20 individuals, although smaller and notably larger numbers are common; some Short-eared Owl roosts may hold more than 100 individuals. Communal roosts of Northern Long-eared Owls occur in dense thickets of deciduous trees in the western USA and Europe and in conifer groves in the eastern USA, whereas those of Short-eared and Marsh Owls are typically on the ground amid tall grasses and weeds. Small numbers of Short-eared Owls occasionally roost with Northern Long-eared Owls in trees. Hunting areas around communal roosts overlap widely, and agonistic interactions typically are confined to cases where the paths of two courting birds bring them into close contact with one another.

Owls exhibit the typical range of comfort movements and maintenance behaviour observed in other groups of birds. Sunning, bathing, dusting, preening, scratching (under as opposed to over the wing), and stretching have been described for several owl species, and no doubt occur in all of them. To date, anting behaviour is unknown in owls.

Allopreening, in which one individual preens another, usually its mate, has been described for at least 17 species of Strigidae in the wild. These are the Eurasian Scops-owl, Western and Eastern Screech-owls, Great Horned Owl, Eurasian and Verreaux's Eagle-owls, Tawny, Spotted, Barred, Ural and Great Grey Owls, Northern Hawk-owl, Eurasian Pygmy-owl, Little and Burrowing Owls, Powerful Owl and Northern Long-eared Owl. The behaviour often occurs between pair-members and is also observed, though less frequently, among siblings or between adults and their young. Researchers have suggested that allopreening is a means of reducing or redirecting aggression, but in owls the behaviour is peaceful and without aggression. Whatever its origin or function, allopreening in owls appears to be a non-aggressive, ritualized type of behaviour, and it is probably indulged in by many more species than the 17 listed above.

Voice

Voice plays an important role in the lives of owls, which is not surprising for a largely nocturnal group that cannot easily communicate through visual displays. The loud vocalizations of many species have given them their names, both common and scientific. For example, the Eurasian Eagle-owl is known as "Uhu" in

Whenever they appear during the daytime, owls are likely to be mobbed by small birds. This anti-predator strategy is practised by a wide range of avian species throughout the world, and involves loud calls and a variety of displays; sometimes the potential enemy is struck by the mobbing birds. The same treatment is handed out to owls that are discovered at their daytime roost. This White-browed Hawk-owl may appear fairly oblivious to the attentions of a male Madagascar Paradise-flycatcher (*Terpsiphone mutata*), but it is not uncommon for the predator to be forced to move to a different perch to escape the mobbing.

Germany, "Huuhkaja" in Finland and "Buho" in Spain; all are names that refer to its booming two-noted call. The boobook owls of Australasia comprise another group with onomatopoeic etymology. The Spectacled Owl is known as "Oropopo" in Costa Rica, a good imitation of its primary call. In English, the screech-owls are obviously named for one of their calls, as are the saw-whet owls, which are named after a call that supposedly sounds like a saw being sharpened.

Because strigid vocalizations are innate, rather than learned, they provide valuable clues for species limits and phylogenies in a family where plumage and other morphological characters are very similar among species (see Systematics). For instance, vocal differences enable two groups to be distinguished within the large genus *Otus*: the Afro-Eurasian scops-owls, with a single, simple primary song, and the New World screech-owls, which have a relatively complex two-part primary song. The two species of white-faced owls of Africa were formerly considered scops-owls, but their complex trilled songs are more similar to those of North American screech-owls; further investigation has shown that they do not appear to belong to *Otus* at all, and they are now placed in their own genus, *Ptilopsis*. Vocal characters have been used many times in recent years to clarify species limits in *Otus* and *Glaucidium*. For instance, the sedentary African Scops-owl was once considered conspecific with the migratory Eurasian Scops-owl because of morphological similarities between the two; their very different songs, however, resulted in the two species being split.

Hybrids between the Barred Owl and the Spotted Owl give unique location calls that are intermediate between the typical calls of the two species, but some of their calls may end in the vibrant "hoo-aww" note characteristic of the Barred Owl's song.

As in other bird groups, owls use vocalizations in many contexts: to attract a mate; advertise a territory; maintain contact between pair-members; indicate alarm; defend the nest or young; and beg for food. The nocturnal habits of owls, however, make it difficult to study these contexts. In many cases, the sex or even

the species giving the vocalization is not known. This is especially true for vocalizations other than the primary songs used to attract a mate or proclaim a territory. Akun Eagle-owls, for instance, emit a high-pitched wailing "heeuuuw" call that is probably used for solicitation, but whether it is given by females, by young or by both is unknown.

Species that are year-round residents on their territories tend to increase the frequency of primary vocalizations when their young have just become independent and are dispersing from their natal territories. The interpretation is that vocal behaviour at this time advertises that a territory is occupied. For instance, the peak season of vocalizations for Japanese Scops-owls is from September to December, and male Ural Owls engage in hooting exchanges in the autumn months in central Sweden. Interestingly, the frequency of hooting among resident *Bubo* species, such as the Great Horned Owl and the Cape Eagle-owl (*Bubo capensis*), increases in mid-winter in temperate latitudes and peaks just before egg-laying. This pattern is repeated in the Spectacled Owl, which breeds from January to May in Costa Rica and gives primary songs only from January through to the end of March. Because the period of parental care of juveniles is prolonged in these species, the period of juvenile dispersal may overlap the time of increased pair-bonding and advertisement for mates.

Nomadic or migratory species vocalize most often when they are advertising territories or establishing new pair-bonds just prior to breeding. For example, the migratory Oriental Scops-owl begins calling in May on its Japanese breeding grounds, in contrast to the autumn calling period of its close relative, the resident Japanese Scops-owl. Vocalizations used to attract mates or to advertise nest-sites, in other words the primary songs, are given early in the breeding season by such non-resident species, usually in late winter or spring in temperate latitudes. Among *Asio*, *Aegolius* and some *Ninox* species, these primary songs are given exclusively by males and function almost solely to attract mates and advertise nest-sites. While trying to attract a mate, a male Northern Saw-whet Owl will deliver its monotonous, tooting

Like many groups of birds, strigids perform a number of actions relating to comfort behaviour. The commonest of these is wing- and leg-stretching, perfectly demonstrated by this Short-eared Owl perched on a fence post in evening light. Since these movements are frequently carried out before a period of foraging, or during a break between two such bouts, they probably serve not only to stretch the muscles and put the feathers in order, but also to ensure that the bird's circulatory and muscular systems are properly prepared for the important activity of hunting.

Planet Earth]

whistle almost continually all night; once a pair-bond is established, however, the male abruptly stops singing and generally restricts its vocalizing to brief calls uttered during food deliveries.

In many other owls, both members of the pair produce similar songs for territory advertisement, courtship and pair-bonding. In almost all of these species, the female's vocalizations are higher-pitched than those of the male, because, in the majority of strigids, the female's syrinx is smaller than the male's. The calls of female Verreaux's and Blakiston's Eagle-owls are lower-pitched than those of their respective mates. The double "buu-bu" song of Blakiston's Eagle-owl seems to function primarily in mate attraction or pair-bonding; within mated pairs it is given only by the male to initiate calling duets, but it is also uttered by unpaired owls of both sexes. Males vocalize more often than females in most species that have been studied, including the Flammulated Owl, Eastern Screech-owl, Great Horned Owl, Barred Owl and Ural Owl.

Intraspecific differences in the primary songs of owls are usually great enough to permit individual identification, even among species with relatively simple songs such as the Eurasian Pygmy-owl. Females may be able to use the primary songs of males as indicators of male quality. For example, B. Appleby and S. M. Redpath found that the sound frequency, or pitch, of songs given by male Tawny Owls in Britain was inversely related to body mass, and that the vibrato section was longer in larger birds, although no vocal characteristics seemed to be related to breeding success. Interestingly, males with parasitic infections produced shorter songs of higher frequency. In Italy, P. Galeotti determined that the rate and the harshness of songs ("hoots") uttered by male Tawny Owls were positively related to aggressiveness in response to song playback, which Galeotti equated with the male's "resource holding potential". The duration and the frequency range of hoots were correlated with reproductive output and the number of years over which a territory was occupied. Because males increased their rate of hooting when females joined them in vocal displays, Galeotti suggested that male hoots functioned in female choice.

New World *Otus* generally have two distinct song types that are used in territorial and courtship contexts. The Whiskered Screech-owl gives a series of hollow, whistled notes to advertise its territory, but often switches to a staccato "Morse code" vocalization when duetting with a mate. These two types of song have been well studied in the Eastern Screech-owl, which has a trilled song and a descending whinny. G. Ritchison and associates noted that trilled songs are given by both sexes, but predominantly by males, and are used in both territorial and courtship situations. Males use a prolonged version of the trilled song to advertise a prospective nest-site, and mated pairs often duet using the trilled song. Whinny songs are used almost exclusively for territorial advertisement and defence. Two neighbouring males may begin a territorial encounter with whinny songs, but then switch to trilled songs after they have approached each other. The louder, highly modulated whinny song is well suited to long-distance territorial proclamations, because it carries better through thick forest.

Mated pairs of many owl species frequently duet, particularly at the beginning of the breeding season. Males usually initiate duets, and the female replies immediately after the male's call, or even before his call has ended. The male Pel's Fishing-owl gives a sonorous hoot followed by a deep grunt, "hooooommm-hut"; the female answers this with a higher, softer hoot followed by a shorter second double-noted "hoot-oot". The male Blakiston's Eagle-owl gives a double "buubu" call that is followed immediately by the female's lower "bu." In the Spotted Eagle-owl, the male gives a primary "hoo-whoohoo" song, which is sometimes followed so closely by the female's slightly higher-pitched song that the two vocalizations sound like only one. Similarly, female Eurasian Scops-owls often duet so closely with their male partners that the monotonously repeated calls sound like a single, but two-part, call. The calls of two or more adjacent male scops-owls, while given at a very regular rate, are not synchronized with each other, and the pattern of calling thus differs from that of duetting mates. Duetting bouts in the Eastern Screech-owl are

A vital aspect of an owl's daily maintenance routine involves bathing. This has been recorded for many species, including the Austral Pygmy-owl, and almost certainly occurs among all members of the Strigidae. Standing in shallow water, as at the edge of a pool or river, the owl ruffles up its feathers and repeatedly dips its breast and head while vigorously shaking its body, so that its entire plumage is wet or damp.

This is followed by a session of feather-oiling and preening, made easier by the preceding wetting of the plumage. Further maintenance activities include sunning and dusting.

[*Glaucidium nanum*,
Torres del Paine
National Park, Chile.

usually initiated by the male, and consist of trilled "bounce" songs that serve to identify the individual callers and advertise the presence of a mated pair.

Owls also emit a wide variety of calls to solicit feeding or copulation, to show alarm, to discourage predators, or simply to maintain contact with their mates or young. These calls are less familiar than primary songs, and full repertoires are known for only a few species. S. Bondrup-Nielsen provided a thorough account of the vocalizations of the Boreal Owl, identifying six adult calls and two nestling calls. The primary territorial and mate-attracting song is given exclusively by the male. He also gives a softer version of this song to advertise the nest-hole to a prospective mate and to announce his arrival with food. The female answers the male's song with a "chuuk", and responds to the feeding call with a high-pitched begging call that perhaps is homologous with the begging calls given by nestlings. A low-intensity "moo-a" is given in contact situations, and a high-intensity "skiew" alarm call is given as a warning to territorial intruders and perhaps to potential predators. A very similar array of vocalizations is given by the closely related Northern Saw-whet Owl.

Another common type of repertoire is that of Verreaux's Eagle-owl. The primary song of this species is a grunting "hook hook", given by both sexes; a fast series of hoots is also used in courtship. The male gives a soft bubbling call to advertise the nest-site, and both adults emit "whok" alarm notes. The food-begging call of adult females and young is a long, hissing whistle; younger nestlings cheep and chitter.

J. Olsen and S. Trost studied the repertoire of the Southern Boobook in Australia and noted five main vocalizations. The "boobook" vocalization was given only by males, apparently as a territorial advertisement song as well as to communicate with the female. Males also gave a "croak" call while engaged in vocal duels with neighbouring males. Females gave a single hoot in reply to the "boobook" call, as well as a "bray" call. The latter was usually used in soliciting food, and perhaps copulations, from males. Young birds uttered "trill" calls while begging for food; this call may develop into the "bray" call in females.

When Eastern Screech-owls first detect a potential predator, they give a low-intensity warning to mates and young with

standard trill and whinny calls. If the threat is perceived as more serious, they give loud bark and screech calls, presumably as a warning to the potential predator or intruder. One of the most interesting alarm calls is the rattling "hiss" produced by young Burrowing Owls when something threatens them in their burrow. This call is unnervingly similar to the sound of an alarmed prairie rattlesnake (*Crotalus viridis*), and it certainly causes human intruders to think twice before reaching into a burrow. Indeed, experimental tests of the Burrowing Owl's rattle call led M. P. Rowe and associates to conclude that the call is a form of Batesian mimicry that the owls use to discourage predators from entering nest burrows.

During the early stages of the nestling period, most owlets give high-pitched chirping calls when hungry; these begging calls gradually change to species-specific hisses or shrieks as the birds get older and leave the nest. Nestling and fledgling Flammulated Owls repeatedly utter a short gasping call when hungry, whereas young Southern White-faced Owls emit a long hissing "hooooow" lasting up to 35 seconds. Juvenile begging calls often develop with age into adult contact calls, or into solicitation calls used by females during courtship. For instance, juvenile Spotted Owls give a raspy whistle when begging for food; after six months of age, this call changes to the purer, whistled "coo-whoop" given as a contact call, primarily by adult females. The female African Wood-owl often delivers a high "wheow", which the male answers with a single low hoot or a series of hoots.

One sound that is probably common to all owls, although it is not a vocalization produced in the syrinx, is the bill-snap. This loud popping noise is made by owls from as young as a few days old, and is used when a predator or other perceived threat is very close. Another mechanical sound used by species of the genus *Asio* is the wing-clap. Both sexes wing-clap in courtship and in agonistic encounters, but the sound is produced most regularly by males during courtship flights. Male Northern Long-eared and African Long-eared Owls wing-clap singly at irregular intervals, whereas male Short-eared Owls wing-clap in a rapid series, especially during aerial courtship displays.

Food and Feeding

More is known about the food habits of owls than any other aspect of their ecology, perhaps because diet is one of the easiest facets of their biology to study. This statement might seem counterintuitive given that actual observations of foraging owls are quite scarce. Our knowledge of the food habits of owls is based mostly on analyses of their pellets, which are compact packages of hair, bone and other indigestible items that owls regurgitate after finishing a meal (see Morphological Aspects). A widely under-appreciated fact is that pellets are produced also by many species of non-raptorial birds, including cormorants (Phalacrocoracidae), herons (Ardeidae), gulls (Laridae), waders (Scolopacidae), shrikes (Laniidae), crows (Corvidae), nuthatches (Sittidae) and even wood-warblers (Parulidae). Owl pellets, however, are especially large and compact, and thus are persistent in the environment and easy for researchers to find. Moreover, because owl pellets often contain the identifiable remains of small animals, they provide a reasonably accurate and easily quantifiable sample of the types of foods eaten by owls.

Owls feed on a wide variety of vertebrates and invertebrates. While nothing at all is known about the diet of approximately two dozen species of strigids, it is probably safe to say that all owls are exclusively carnivorous. Although plant matter has been reported in the diets of several owl species, the consumption of such vegetable material has been well documented only for the Little Owl. One must wonder whether some of the plant material that has appeared in stomach contents and pellets of owls actually originated in the digestive tracts of animals eaten by the owls. Suffice it to say that virtually all strigids make their living by dispatching live animals, although several species feed on carrion from time to time.

Owls and the diurnal birds of prey, the Falconiformes, have converged on a raptorial lifestyle. Not surprisingly, the two groups resemble each other morphologically, and they overlap widely in

An additional important part of maintenance behaviour is self-preening, also known as autopreening. This generally follows application of oil from the preen gland, and its primary functions are to remove any soiling or debris from the plumage and to ensure that all the feathers are properly arranged. Here, a Great Grey Owl is preening its tail feathers in the shade of a tree trunk; the intricate and delicate patterning of the plumage is shown well in this view.

[*Strix nebulosa nebulosa*, Yellowstone National Park, Wyoming, USA. Photo: Beth Davidow/Planet Earth]

One of the 17 species of Strigidae for which allopreening has been recorded is the Burrowing Owl. This distinctive behaviour, which is widespread among avian families, involves the preening of one individual by another, and is often reciprocal. In most cases it seems to be practised by the two members of a pair, although it occasionally occurs between an adult and its young, or among siblings.

The function of allopreening is not fully understood. One proposed explanation is that it serves to reduce or redirect aggression, but this would seem not to apply in the case of owls. With strigids, allopreening appears to be a ritualized kind of behaviour, being carried out in a peaceful and non-aggressive manner. Furthermore, since the preening bird frequently performs this action on those parts of the other bird, usually the head, which are difficult for the latter itself to reach, it is likely that the behaviour also plays a role in feather care. Although allopreening has been recorded for only a comparatively small number of owl species, all of which are relatively well studied, one may speculate that it is carried out by many more species; for birds that are rather secretive and largely nocturnal, such behaviour would be difficult to observe.

The majority of owls are night-time hunters, and a good many are strictly nocturnal, rarely seen during the daytime unless located by chance at their roost. The latter category includes nine genera, all the members of which are, with only few exceptions, active only at night. A typical example is the genus *Strix*. This Black-banded Owl was photographed at night, about 30 m above ground in lowland rainforest.

[*Strix huhula huhula*, Napo River, north-east Ecuador. Photo: Robert Behrstock]

diet. Because of their nocturnal habits, however, the owls have a somewhat limited repertoire of foraging methods compared with diurnal raptors. For example, a carrion-feeding guild, such as occurs among the Old World vultures, is absent in the Strigiformes. Unlike several species of New World kites (Accipitridae), no owls specialize on gastropods. Nor do any reptile specialists exist among the owls, in contrast to the snake-eagles (*Circaetus*), serpent-eagles (*Spilornis*) and *Leucopternis* hawks, and no owls have evolved to pursue birds in fast-flying tail-chases in the manner of many species of falcon (*Falco*).

In general, the size of an owl is correlated with the size of its prey, but the frequency distribution of prey size is skewed towards smaller species such that large owls often take small prey items. For instance, breeding Snowy Owls, which weigh 1800-2300 g, feed mostly on lemmings that weigh 50-80 g, and Eurasian Eagle-owls and Great Horned Owls, at 2500-4000 g and 1200-1700 g, respectively, routinely eat rodents weighing only 30 g and even take shrews less than 10 g in mass. In short, the larger owls probably seldom pass up a small mammal that presents itself at the right place and time, which may result in a great deal of overlap in food habits among co-existing owls of vastly different sizes.

Most owl species that inhabit the tropics incorporate invertebrates into their diet to some extent. Of the 40 species of *Otus* for which dietary information is available, 75% appear to be insect specialists. The proportion of invertebrates in the diet tends to decrease with increasing latitude, but two species of *Otus* that inhabit temperate latitudes, the Flammulated Owl and the Whiskered Screech-owl, feed almost exclusively on invertebrates. Major insect groups in the diets of *Otus* include moths, beetles and crickets. These may be caught on the ground by pouncing from a perch, or snatched from the forest canopy or out of the air after a short sallying flight. Most strigids use their talons to capture insects, but some smaller species seize moths and other flying insects in their bills, much as tyrant-flycatchers (Tyrannidae) do. An 1899 account of an Andaman Scops-owl (*Otus balli*) feeding on caterpillars stated that "it sidles up and down the boughs of small trees in a very parrot-like manner". Presumably, it used its beak to pluck caterpillars from the vegetation, but few details were provided.

Within the tropics, the proportion of insects in the diet also decreases with increasing body size of the owl. Yet, in Africa, Fraser's and the Akun Eagle-owls feed almost entirely on in-

sects. The latter species has especially small feet and weak talons for an eagle-owl, and it feeds mostly on cockroaches and beetles. Other strigids that are largely insectivorous include the Elf Owl from the deserts of the American South-west, the Maned Owl from Africa, the Crested Owl from the Neotropics, the Brown Hawk-owl from Asia, the Jungle Hawk-owl from New Guinea, and the Christmas Hawk-owl from Christmas Island in the Indian Ocean. Most of the evidence for insectivory comes from pellets, but Christmas Hawk-owls have been observed plucking moths and beetles from the foliage of the forest understorey, as well as hawking insects in the light cast by streetlamps.

Although no owl specializes on non-insect invertebrates, many non-insect prey are consumed by strigids. Eurasian Scops-owls, Tawny Owls and Little Owls are well known for their habit of pulling earthworms from the ground with the beak, and the Laughing Owl of New Zealand has also been reported to take earthworms. Crayfish and crabs are eaten by several species of *Bubo*, *Ketupa* and *Scotopelia*, and by the Brown Hawk-owl; scorpions are consumed by Western Screech-owls, Northern White-faced Owls, Great Horned Owls, Cape and Pharaoh Eagle-owls, and Hume's Owls; leeches occasionally fall prey to Eastern Screech-owls; and Whiskered Screech-owls, Great Horned Owls and Palau Owls feed on centipedes. Pel's Fishing-owl sometimes eats mussels, and Eastern Screech-owls, Spotted Eagle-owls and Barred Owls have been known to catch snails. Analysis of stomach contents of road-killed Northern Saw-whet Owls in the Queen Charlotte Islands, off western Canada, revealed that the birds had consumed intertidal invertebrates such as amphipods and isopods.

As their names suggest, the fish-owls and the fishing-owls are the closest thing to fish specialists among the strigids, although none of the six species in these two genera feeds exclusively on fish. All six species, plus Blakiston's Eagle-owl, are closely tied to fresh water, where they capture aquatic organisms at or just below the surface. Fish-eating owls typically swoop down to the water from a perch to catch fish, but Blakiston's Eagle-owl, the three fish-owls and Pel's Fishing-owl are also known to seek prey by wading in shallow water. Whether fish are detected by sight or sound is not known with certainty, but at least one species, the Tawny Fish-owl, often catches fish in broad daylight, and Blakiston's Eagle-owl will stand near holes in the ice, waiting for potential victims to come to the surface; presum-

While nocturnal hunting is the norm among the Strigidae, many species also hunt at dusk and dawn, and sometimes even during the day. One of the better-known daytime hunters is the Short-eared Owl. Although this owl will forage during the dark hours of the day, it is by no means uncommon for it to be on the wing and actively seeking prey in the late afternoon, or at times earlier, especially in the northern hemisphere.

[*Asio flammeus flammeus*,

NHPA]

ably, prey is detected by sight in both cases. Because species of *Ketupa* and *Scotopelia* lack sound-dampening fringes on their outer primaries, it might reasonably be concluded that their ability to locate prey by sound is not especially well developed. Five other species that feed to some extent on fish, namely the Eastern Screech-owl, Great Horned Owl, Eurasian and Verreaux's Eagle-owls and Barred Owl, are generalists that take a great variety of prey types and perhaps only rarely ignore a potentially suitable prey item, be it on land or in the water.

Amphibians are not a major food of any species of strigid, but frogs are fairly common in the diets of fish-owls and fishing-owls. Tree-frogs (Hylidae) are prevalent in the diet of the endangered Seychelles Scops-owl (*Otus insularis*), and various types of frogs are eaten by at least two dozen other species spread among the genera *Otus*, *Gymnoglaux*, *Bubo*, *Strix*, *Pulsatrix*, *Glaucidium*, *Athene*, *Aegolius*, *Ninox* and *Asio*; presumably, frogs have gone unnoticed in the diets of other species, too. Certainly, the numerous species of tree-frogs that are vocal at night must be eaten by many species of *Otus* in the tropics. Burrowing Owls in Minnesota, USA, were observed to catch "at least as many amphibians as mammals, yet only mammalian remains were found in pellets". In the desert of south-western Idaho, Burrowing Owls routinely stockpile spadefoot toads (*Spea intermontana*) at the entrances to their nesting burrows, only for the toads to be seemingly ignored by the hungry owlets. Both cases suggest that Burrowing Owls sometimes catch anurans and then find them unpalatable. Eastern Screech-owls and Barred Owls are among the few strigids known to eat salamanders.

Many reptiles are diurnal, and they seldom figure prominently in owl diets. Snakes are eaten, albeit in relatively minor proportions, by various species of *Otus*, *Bubo*, *Ketupa* and *Strix*. Rattlesnakes (*Crotalus*) are among the reptilian prey taken by Great Horned Owls in western North America, and a recent study revealed that snakes and lizards made up nearly 16% of the prey items taken by a nesting pair of this large strigid in the desert of Baja California, Mexico. Eurasian Eagle-owls, too, sometimes include adders (*Vipera berus*) in their diet. Barred Owls in the south-eastern USA are known to eat baby alligators (*Alligator mississippiensis*) and the occasional turtle.

The work of F. R. Gehlbach on Eastern Screech-owls of the subspecies *hasbroucki* is especially interesting with regard to rep-

tilian prey. Gehlbach found nine species of snake among the prey items cached in nestboxes and natural cavities over a twelve-year period in central Texas, USA. Interestingly, one species, the Texas blind snake (*Leptotyphlops dulcis*), was often carried alive to the owl nests, whereas all other prey was delivered dead. Although these snakes were occasionally consumed by the owls, most of them remained alive in the nest-cavity debris, where they ate insect larvae such as fly maggots. Owlets in nests with live blind snakes grew faster and had a higher rate of survival than those from nests without live snakes, perhaps because, in the absence of these reptiles, the insect larvae competed with owlets for prey delivered by the adult owls. Gehlbach suggested that the relationship was commensal, with the screech-owls benefiting from increased reproductive success and the snakes being unaffected by transport to a nest with a rich source of food. Without question, the owls did attempt to kill the snakes, as evidenced by Gehlbach's direct observations on two occasions and by talon wounds on live snakes found in the boxes. Blind snakes that survived the experience, however, remained in the boxes without further injury until two to seven days after the owlets had fledged, presumably leaving in response to the lack of food that resulted after the owls stopped attending the nests.

Species of *Glaucidium* feed on reptiles to a greater degree than do any other strigids. This makes perfect sense, given that pygmy-owls and owlets are the most diurnal of the strigids that live in warmer climates, where reptiles are abundant. Lizards are known to occur in the diets of fully 70% of the *Glaucidium* species, and the true proportion is probably higher, because no information on food is available for several species. The importance of lizards for one species of this genus was demonstrated by G. A. Proudfoot's study of Ferruginous Pygmy-owls at the northern edge of their range in South Texas. Using a combination of prey remains, video recording and direct observation, Proudfoot determined that the owls fed on 36 different prey species, with nine species of lizards making up 22.5% of the prey remains found in nest cavities. Video recordings and observations from hides revealed that the owls were largely diurnal, which corroborated anecdotal information on foraging behaviour in the heart of this owl's range in Central and South America.

Many nocturnal owls probably obtain most of their avian prey opportunistically. This likelihood is based on the fact that most

of their prey species are diurnal and thus would not be active while the owls are hunting. Examples illustrating this point include Western Screech-owls in Idaho that feed on communally roosting Common Starlings (*Sturnus vulgaris*) and Red-winged Blackbirds (*Agelaius phoeniceus*); Great Horned Owls in Canada that take American Coots (*Fulica americana*) from open-water roosts at night; Forest Eagle-owls in Asia that take Kalij Pheasants (*Lophura leucomelanos*) and Red Junglefowl (*Gallus gallus*) from their night-time roosts; and Northern Long-eared Owls in Iraq that prey on roosting House Sparrows (*Passer domesticus*). Crepuscular strigids may take a more active role in the pursuit of avian prey. Breeding Eastern Screech-owls in central Texas concentrate their hunting efforts around dawn and dusk; they often take passerines that are foraging when visibility, and thus the ability to detect predators, is reduced. The larger strigids may actively pursue smaller owls and other nocturnal species at night. H. Mikkola's thorough review of owl predation on other owls in Europe revealed 768 records of Eurasian Eagle-owls killing Northern Long-eared Owls and 286 records of their killing Tawny Owls, with Barn Owls (*Tyto alba*), Little Owls and Boreal Owls also taken in fairly high numbers. In addition, Mikkola uncovered twelve records of Ural Owls preying on Boreal Owls, and 23 cases of Tawny Owls eating Little Owls. It should be noted that, because the total number of prey items exceeded 22,000 for the Eurasian Eagle-owl and 4000 for the Ural Owl, other strigids represented only a small fraction of each species' overall diet. At least eight species of owl have been recorded in the diet of

the Great Horned Owl in North America. On Protection Island, off the coast of Washington State, breeding Great Horned Owls feed almost exclusively on Rhinoceros Auklets (*Cerorhinca monocerata*) that attend a large nesting colony at night, and nocturnal seabirds are major food items for some Short-eared Owls that inhabit the Galapagos Islands.

Perhaps the most interesting manner in which owls prey on other birds is by active pursuit during the day. Diurnal hunting is a necessity at high latitudes, where there is more or less 24-hour light during the summer months. Breeding Snowy Owls feed mostly on lemmings and voles, but also take ptarmigans (*Lagopus*), various waders (*Charadrius*, *Numenius*) and nestling passerines. Alcids, waterfowl, Eurasian Black Grouse (*Tetrao tetrix*), Grey Partridges (*Perdix perdix*) and Rock Doves (*Columba livia*) are among the avian prey of this owl in winter. Indeed, along the British Columbian coast of western Canada, wintering Snowy Owls seem to specialize on waterfowl, especially Mallards (*Anas platyrhynchos*), Northern Pintails (*Anas acuta*) and American Wigeons (*Anas americana*). With its long tail, pointed wings and powerful flight, the Northern Hawk-owl resembles an *Accipiter* hawk or a falcon, and it is also diurnal to a large extent. Although mammals dominate its diet during the breeding season, in winter it tends to take more birds, including grouse, woodpeckers (Picidae) and jays (Corvidae).

Pygmy-owls and owlets are the champion bird-pursuers among the strigids. Birds have been recorded in the diets of 83% of the 23 species of *Glaucidium* for which dietary information is

Owls, like the diurnal birds of prey (Falconiformes), are essentially carnivorous. Indeed, for those owl species for which at least some dietary information is available, they would appear to be exclusively so. A wide range of vertebrate and invertebrate prey is taken, in most cases the food being located by audial clues. The method of capture employed by strigids is characteristic. As demonstrated by this Tawny Owl on the point of seizing a mouse, the owl extends its legs and feet fully downwards and, with feet together, opens its toes to form a rectangle; then, on impact, it rapidly squeezes its talons together to kill the prey, often biting the back of the victim's skull immediately thereafter as if to make certain.

Despite their renown as predators of the night, some owls can regularly be seen hunting by day, especially at high latitudes, where local conditions can require this in both summer and winter, though for rather different reasons.

The Magellanic Horned Owl of the southern half of South America is mainly active around dusk and dawn, but can sometimes be seen hunting by day. This form has recently been split from the Great Horned Owl (*Bubo virginianus*), on the basis of its much smaller size, together with its quite different vocalizations, and also its DNA.

available. Data summarized by H. Mikkola show that birds make up 44% of the diet of nesting Eurasian Pygmy-owls in Finland, 37% in Sweden, 56% in Norway, and up to 80% in central Europe. Birds are also a prominent component in the diets of Collared Owlets in Asia, Andean Pygmy-owls in South America and Northern Pygmy-owls in the USA. Indeed, many individuals of the last-mentioned species vacate the mountain forest in winter to reside in suburban neighbourhoods, where they terrorize House Finches (*Carpodacus mexicanus*) and House Sparrows at bird-feeders. Some pygmy-owls routinely kill birds that are larger than themselves. For example, Ferruginous Pygmy-owls dispatch Eastern Meadowlarks (*Sturnella magna*); Austral Pygmy-owls prey on juvenile Chilean Tinamous (*Nothoprocta perdicaria*) and adult Eared Doves (*Zenaidura macroura*); and Northern Pygmy-owls have been observed killing American Robins (*Turdus migratorius*) and Pine Grosbeaks (*Pinicola enucleator*). These large prey items are almost certainly too heavy for the owls to lift in one piece. In the cases of the robin and the grosbeak, each owl pulled its victim to the shelter of an overhanging shrub, where it proceeded to pluck and consume it. Perhaps the "false eye-spots" displayed by many pygmy-owls and owlets (see Morphological Aspects) function to reduce predation on the owls themselves while they are busy processing prey items that are too large to be transported to the safety of a tree.

Fledgling birds are actively hunted by Eastern Screech-owls, Snowy Owls and Eurasian Pygmy-owls, and many other strigids probably take fledglings opportunistically. No species of strigid, however, is known to be an egg predator. Eggshell fragments found in Northern Long-eared Owl pellets during the breeding season in the USA and Norway suggest that females eat the shells of their hatched eggs, presumably for the purposes of nest sanitation rather than for the nutritional value of the shells.

Small mammals such as shrews, mice, voles, lemmings and rats are major prey items for many strigids, especially in temperate and sub-Arctic latitudes. All of the Holarctic species feed primarily on small mammals, and some Snowy, Boreal and Short-eared Owls are so dependent upon voles or lemmings, whose populations are cyclical, that individuals wander from place to place, settling to breed only in areas where such rodents are abundant. The dependence on cyclical rodents may vary with latitude. For instance, in the northern part of their range in North

America and the western Palearctic, Northern Long-eared Owls feed mostly on voles and are highly nomadic. In the deserts of the Great Basin and the south-western USA, however, they feed more on non-cyclical species such as deer-mice (*Peromyscus*) and heteromyid rodents (*Perognathus*, *Dipodomys*) and do not appear to be so nomadic. Similarly, Short-eared Owls are migratory and/or nomadic in the northern half of their range in Eurasia and North America, where cyclical voles typically account for more than 90% of their diet, but they are less nomadic or even sedentary in the southern part of their range and in the Galapagos and Hawaiian Archipelagos, where cyclical rodents are absent.

Bats are incidental prey items for many strigids, especially *Otus*, *Bubo*, *Strix* and *Ninox*, although no species, except perhaps the Black-and-white Owl, specializes on them. Some individual owls have learned to take advantage of large concentrations of bats. Each night during the summer, at sunset, a dense stream of Mexican freetail bats (*Tadarida brasiliensis*) pours out of Carlsbad Cavern in New Mexico, USA. Over the years, there are many reports of one or two Great Horned Owls flying back and forth through this virtual river of bats until they succeed in seizing a hapless one from the air; the owls cannot outmanoeuvre the bats, and so they grasp into the crowd rather than single out individuals. An Eastern Screech-owl was observed attempting to snatch little brown bats (*Myotis lucifugus*) in a similar manner as they entered a communal roost in an abandoned farmhouse in Ontario, Canada, and in South Dakota, USA, a researcher watched a small owl, probably that same species, grab a silver-haired bat (*Lasiurus noctivagans*) that had landed on a tree trunk soon after leaving a roosting cavity. In Africa, Spotted Eagle-owls have been seen catching bats that feed on insects attracted to streetlights. Similarly, in Australia, Rufous and Powerful Owls take flying-foxes (*Pteropus*) from within the forest canopy.

The eagle-owls are the world's most powerful strigids. Collectively, they take a great variety of mammals, and their diets vary widely with geography. In some parts of its range, the Eurasian Eagle-owl feeds on medium-sized mammals such as hares (*Lepus europaeus*) and rabbits (*Oryctolagus cuniculus*), but it also takes larger items such as the young of roe deer (*Capreolus*), chamois (*Rupicapra*) and ibex (*Capra*); also included in its diet are martens (*Martes*) and foxes (*Vulpes*). The Great Horned Owl, although smaller than its Eurasian relative, is nonetheless just

The prey taken by some strigids is very large when considered in relation to the size of the owl itself. This is particularly marked among the small pygmy-owls and owlets of the genus *Glaucidium*. Most members of this genus include a fair proportion of birds in their diet, catching many of their victims by actively pursuing them in flight. These owls are renowned for their ability to take prey as large as or larger than themselves, and the ferociousness of these tiny predators is borne out by the fact that they invariably elicit a fierce mobbing response from other birds that come across them. When dealing with such large prey, the pygmy-owl, unable to lift and carry off such a heavy weight, will often drag its victim to a sheltered spot, where it can consume its meal in relative safety. *Glaucidium* owls generally pluck bird prey, before swallowing the food piecemeal; since plucking can take a little time, the owl would risk being preyed on itself were it to carry out this process in an exposed position. This Northern Pygmy-owl, having successfully killed a Common Starling (*Sturnus vulgaris*), will need to act quickly.

[*Glaucidium californicum californicum*, Falkland, British Columbia, Canada. Photos: Sid Roberts/Ardea]

Invertebrates figure to a varying degree in the diet of most strigids, and a not insignificant number of owls appear to specialize on insects. Many *Otus* species fall into the latter category. The Eastern Screech-owl, for instance, takes a large number of insects, and a *Cecropia* moth affords a quite sizeable and highly nutritious meal. Since moths, beetles and crickets are mostly nocturnal, it is hardly surprising that they are widely represented among the insect prey of owls.

Bruce Coleman]

as eclectic in its choice of larger mammalian prey. Lagomorphs (*Lepus*, *Sylvilagus*) are common prey of this strigid throughout much of North America, often accounting for more than 50% of its diet, which also includes unusual prey items such as skunks (*Mephitis mephitis*), muskrats (*Ondatra zibethica*), raccoons (*Procyon lotor*) and even porcupines (*Erethizon dorsatum*). In South America, Magellanic Horned Owls take relatively small numbers of the introduced lagomorphs that occur there in abundance, concentrating instead on a variety of native mammals weighing between 30 g and 300 g. Verreaux's Eagle-owls kill hedgehogs (*Atelerix*), vervet monkeys (*Cercopithecus aethiops*), and even young warthogs (*Phacochoerus*), and Blakiston's Eagle-owls occasionally take domestic cats and dogs! The Powerful Owl is the largest and most formidable strigid in Australia, where it fills a niche similar to that of eagle-owls on other continents. Powerful Owls use their long legs and muscular feet to seize possums (*Phalanger*, *Pseudocheirus*, *Trichosurus*), sugar gliders (*Petaurus*) and other arboreal marsupials from the forest canopy, and they also snatch relatively large prey from the forest floor.

Much of the information on food habits of Neotropical owls is based on stomach contents of small numbers of collected specimens. An exception is the Guatemalan study by R. Gerhardt and associates, who monitored a single Black-and-white Owl nest for three consecutive seasons, as well as eight Mottled Owl nests. Data were gathered by a combination of pellet analysis and observations of radio-tagged males. Mottled Owls fed primarily on insects, mostly coleopterans and orthopterans, and also ate small rodents, whereas the Black-and-white Owl fed to a great extent on bats, in addition to insects. Overall, 73% of the pellets of Black-and-white Owls contained bat fur and bones, whereas only 56% of the Mottled Owl pellets contained vertebrate remains. Both species hunted from perches and were exclusively nocturnal. Mottled Owls hunted in dense climax forest, and the radio-tagged Black-and-white Owl tended to hunt in semi-open areas near ponds. The only other in-depth study of the food habits of Black-and-white Owls was in Venezuela, where, in terms of biomass, the species fed mostly on bats and small birds.

Fossil pellets dating from 10,000 years ago to late in the nineteenth century have yielded a fascinating account of the diet and ecology of Laughing Owls from the South Island of New Zealand. The owls fed on a wide variety of animals, which included at least 20 species of birds, three bats, two introduced rodents, four lizards and two frogs. Most of the prey weighed 50-150 g, and more than half of the species were nocturnal. The general picture that emerged was that Laughing Owls were opportunistic nocturnal predators that obtained most of their prey in forest habitats.

The keen ability to detect prey by sound allows some strigids to capture a prey item without seeing it. For example, Great Grey Owls and Northern Hawk-owls often capture small mammals by plunging into the snow, sometimes as deep as 45 cm, after hearing the movements of the prey. Similarly, during summer, Great Grey Owls capture pocket gophers (*Thomomys*) below ground by punching through the earthen burrows made by the gophers.

Caching behaviour is well developed in strigids, especially in species that inhabit the more northerly latitudes. Northern Hawk-owls may cache up to 20 prey items in three hours during winter, and Boreal Owls store an average of seven items in their nestboxes during peak vole years. Prey items are typically stashed in the crotch of a tree or within nesting or roosting cavities. No studies have examined how long prey remain cached before being retrieved, but some items are stored for at least several days before consumption. During summer, uneaten items would begin to rot within a few days, so long-term storage is unlikely to be beneficial. The situation is different in winter, however, when cool temperatures could preserve stored prey for weeks. The Eurasian Pygmy-owl, perhaps the most prolific food-cacher amongst Palearctic owls, tends to store rather little in summer but will put more prey items aside around the turn of the year, when the frost helps to conserve them. Indeed, cached prey animals may freeze solid during winter. Accordingly, Great Horned, Boreal and Northern Saw-whet Owls have been observed thawing frozen prey with the body, adopting a posture similar to that of an incubating or brooding female. Body heat applied to the

prey item gradually warms it to the extent that chunks of meat can be torn off and consumed.

Conventional wisdom suggests that strigids are opportunistic predators: that is, within a range of prey sizes that can be handled efficiently, most species probably take prey in proportion to its availability. In some strigids, what appears to be specialization on voles during peaks in the vole cycle can probably be attributed to voles being so abundant that they numerically dominate other available prey species. It is important to note, however, that the concept of prey availability is not restricted to the mere abundance of individuals. Perhaps in response to predation risk, some desert rodents confine their foraging to the vicinity of shrubs and other cover that will protect them from foraging owls. In addition, desert rodents such as kangaroo rats (*Dipodomys*) have inflated auditory bullae (bones in the skull) that allow them to hear flying owls, and elongated hind limbs that enable bipedal locomotion to flee from attacking owls. This anti-predator morphology may allow these species to forage in the open, and at the same time would reduce their availability to foraging owls.

Further proof that habitat selection by prey animals can influence their availability to owls comes from a study of Rufous-legged Owls carried out in the forest of southern Chile, where D. R. Martínez and F. M. Jaksic demonstrated that arboreal, scansorial (tree-climbing) and cursorial (ground-running) mammals of similar size occurred in similar abundance, yet the owls fed preferentially on the arboreal (*Irenomys*) and scansorial species (*Oryzomys*) and avoided the cursorial ones (*Akodon*). *Akodon* tended to occur in terrestrial habitats that provided overhead vegetation, whereas *Irenomys* and *Oryzomys* inhabited tree trunks and branches in old-growth forest where the Rufous-legged Owls concentrated their hunting efforts.

Most strigids use one of two basic hunting styles: "sit-and-wait" hunting from a perch, or "active-search" hunting on the wing. The great majority of species, including most *Otus*, *Bubo*, *Strix*, *Glaucidium*, *Ninox* and *Aegolius*, are sit-and-wait predators that drop or glide from elevated perches to attack prey on the ground. Strigids that use this technique, which is also known as "perch-and-pounce", tend to live in forested habitats that offer a

Small mammals are a staple food for many of the strigids. The most typical of such prey are rodents, taken by a very large number of owl species. The Southern Boobook, although mainly insectivorous, also hunts vertebrates, especially during the breeding season. This individual has captured a bush rat (*Rattus fuscipes*), a common species within the owl's Australian range. In some other parts of the world, where rodent populations are subject to cyclic fluctuations, rodent-dependent strigids are forced to adopt a nomadic way of life, breeding only where their prey happens to be abundant in any given year.

[*Ninox boobook boobook*, New South Wales, Australia.
Photo: Marco Sacchi]

large number of perches suitable for hunting. Sit-and-wait hunters also tend to have higher wing-loading than owls occupying open habitats. In contrast, some open-country strigids, especially Northern Long-eared and Short-eared Owls, have long wings and low wing-loading and use the active-search technique. Active-search foragers hunt by quartering over meadows, fields and shrubland, much as a harrier (*Circus*), and pouncing from the air on prey located by sound or sight. Flight speeds used during active-search hunting tend to be rather slow, and the owls often pull up and hover to investigate a potential prey item. Some sit-and-wait hunters, such as the Great Grey Owl, will also hover like the active-search foragers. Conversely, some of the latter, especially the Northern Long-eared Owl, occasionally hunt from a perch. Variations on the sit-and-wait technique include attacking prey within the forest canopy or in the water rather than on the ground, the first method being illustrated by some *Otus*, *Strix* and *Ninox* species and the second by the fish-owls, fishing-owls and Blakiston's Eagle-owl, while the Snowy Owl will watch from a perch but then pursue and capture its victim in flight. Northern Hawk-owls have been observed running through the snow in pursuit of small mammals, and Burrowing Owls seemingly defy classification as to hunting style, using techniques that include hovering, hopping on the ground, and aerial flycatching.

As it strikes its prey, an owl typically extends its legs and feet downwards and opens its toes, with feet together, in such a way that the eight talons form a rectangle. The eyes are closed during the actual strike, no doubt to help protect them. Prey animals are killed by a rapid squeezing of the talons, often followed by a bite to the back of the skull.

Data on capture success of owls are few, and relate mostly to diurnal species. By persistent observation, F. R. Gehlbach estimated capture success for Eastern Screech-owls and Flammulated Owls that foraged at night. The former were successful in 78% of 72 attempts; capture rate was much higher when the owls hunted insect prey, with 83% of 63 attempts succeeding, than when they pursued vertebrates, when the figure was 56% of nine attempts. When hunting insects, Flammulated Owls were successful in 81% of 31 attempts, a figure comparable to that of Eastern Screech-owls. Capture success of Great Grey Owls in the USA was 33%, and that of Ural Owls in Japan was 27%; in both cases, the birds were hunting small mammals.

Short-eared Owls observed by R. J. Clark at several North American localities were successful in only 22.5% of 577 attempts at small mammals, and Marsh Owls were reported to have a capture rate of only 20% in South Africa. Wintering Snowy Owls in Alberta, Canada, succeeded in 45% of 51 attempts when hunting from a perch; not surprisingly, their success was much higher for attempts on mammals than for those on birds, with respective figures of 54% and 15%. Similarly, wintering Snowy Owls observed in Michigan, USA, were successful in 54% of 48 attempts at mammals, but failed in all 14 of their attempts to capture birds.

One of the more thorough studies of hunting behaviour in strigids was conducted on Northern Hawk-owls in Norway by G. A. Sønnerud. Hawk-owls fly to elevated perches, from which they search intently for mammalian prey. Sønnerud erected artificial perches of three different heights in a clear-cut area of 20 ha, and observed the hunting behaviour of nine individuals over a ten-year period. Perches were placed in a uniform grid throughout the study area, but perch height varied randomly. On average, the owls visited five perches for each attack, and had to perch 13.5 times for each successful capture, which yielded an average success rate of 36%. The higher the owls perched, the farther away they attacked prey, and the farther they moved to subsequent perches. Perch height explained more of the variation in attack and move distances than did the amount of time spent at a perch, and perches from which prey was captured tended to be lower than those that were vacated without a successful capture. The data suggested that the distance between predator and prey was more important in determining whether an attempt was successful than whether a prey animal was detected, and that the movement patterns of hunting hawk-owls served to increase the efficiency with which they searched for prey.

Once an owl has caught prey, the way in which it deals with it depends on the size of the prey animal. Small items are often swallowed whole, but sometimes the head is removed and eaten and the body eviscerated; larger prey items are eaten piecemeal by tearing flesh from the body. Species of *Glaucidium* typically pluck their avian prey. The larger strigids tend to remove the wings from medium-sized or bigger bird prey, and they often discard the head and feet of large avian and mammalian victims.

Larger mammals also figure prominently on the menu of many owls. As a general rule, prey size is correlated with the size of the owl, so that the huge Eurasian Eagle-owl commonly takes hares (*Lepus*) and even bigger mammals. Interestingly, however, the frequency distribution of prey shows a marked bias towards smaller prey items. This massive predator frequently consumes small rodents weighing just 30 g, and even lighter shrews of 10 g and less. It seems that the large owls, notwithstanding their size, will take any small mammal that happens to come their way.

Most of the information on food consumption in strigids comes from captive birds, and thus represents rough estimates in the absence of active foraging and other behaviour that would normally occur in the wild. Not surprisingly, relative food consumption varies with body mass, being higher for smaller species. In the wild, food consumption also varies with ambient temperature, season of year, and activity level of the individual in question. A female Northern Saw-whet Owl weighing 96 g, and kept indoors at a temperature of 18–19°C, required 17.5 g of food per day (18% of body mass) to maintain her body mass. Two male Eastern Screech-owls that weighed 150–160 g consumed 25–33% of their body mass daily when kept in outdoor flight cages at temperatures ranging from 6°C to 21°C. C. D. Marti raised in captivity a single chick from each of three species of strigids, the Burrowing, Northern Long-eared and Great Horned Owls. Beginning when the birds were nearly one year old, Marti measured their daily food consumption in an outdoor aviary, which restricted their flight activity, over an eleven-month period at temperatures ranging from -1°C to 21°C. The Burrowing Owl, a male weighing 160–177 g, consumed an average of 15.9% of its body mass; the Northern Long-eared Owl, a female of 265–304 g, consumed 13.8% of its body mass; and the Great Horned Owl, a male that weighed 1265–1410 g, ate 4.7% of its body mass per day. Other studies of captive Great Horned Owls have estimated daily food consumption at 1.5% to 2.5% of body mass. Free-flying Tawny Fish-owls weighing 2100–2600 g were estimated to consume less than 12% of their body mass per day in Taiwan.

In an elegantly comprehensive study conducted both in the field and in the laboratory in the Netherlands, H. Wijnandts estimated gross energy intake of wild Northern Long-eared Owls throughout their annual cycle, taking into account such factors as seasonal variation in digestibility and the energetic costs of breeding, foraging, flying and moulting. On the basis of a caloric content of 8.0 kJ per gram of prey, Wijnandts calculated a gross energy intake of 292–415 kJ per day during the non-breeding season. From analyses of pellets collected throughout the year, he estimated that voles contributed 55–82% of the owls' energy intake, followed by other small rodents (3–19%), birds (4–26%) and non-rodent mammals (3–9%). Moulting was estimated to add as much as 26 kJ to the daily energy budget, and flying,

based on an average of 158 minutes of flight per night, cost 104 kJ per day.

Breeding

The mating systems of birds are difficult to study, but those of the largely nocturnal owls have proved particularly challenging. Although some classic studies have been carried out, such as H. N. Southern's work on Tawny Owls at Wytham Wood, near Oxford, England, the last two decades have seen a myriad of investigations on owl breeding biology using nestboxes, radio-telemetry, and electronic sensors at the nest, as well as more traditional observational techniques.

Bats are taken by a number of owl species, although they tend to constitute incidental additions to the diet rather than regular prey items. One reason for this may be that owls are generally designed more for silence and stealth than for rapid, agile aerial pursuit. Members of the genus *Ninox*, aptly known as hawk-owls, are amongst the more nimble fliers, and several of them are known to catch bats. This Brown Hawk-owl has caught a leaf-nosed bat (*Hipposideros*).

Most strigids are monogamous, and many species have long-lasting pair-bonds. In Finland, P. Saurola found Ural Owls to be very faithful from year to year, with an annual divorce rate of only 2.7%; Tawny Owls were less true to their mates and had a 12.1% divorce rate. Long-term pair-bonds are common in other members of the genus *Strix*, as well as in *Bubo* and *Otus*. Species of *Asio* and *Aegolius* typically form shorter pair-bonds, usually for only one season. These species tend to be rather nomadic, adult females in particular being prone to disperse

long distances from their former nesting territories during periods of low prey abundance.

Many bird species with monogamous mating systems have been found to engage in extra-pair copulations, but this seems to be rare among owls, at least in the species that have been well studied. In fact, extra-pair copulations have been demonstrated for only two species, the Burrowing Owl and the Flammulated Owl. B. Johnson found evidence of extra-pair fertilizations in two of 31 Burrowing Owl nestlings in a "loose colony" in California. In Colorado, R. T. Reynolds and B. D. Linkhart observed a female Flammulated Owl that copulated with its territorial male and an intruding male on the same night; whether the intruder fathered any of the female's young was unknown. Also in the USA, J. S. Marks and associates, using DNA fingerprinting, detected no extra-pair fertilizations in 49 Northern Long-eared Owl nestlings from ten "semi-colonial" nests in Montana in which nearest-neighbour distances averaged less than 100 m, and S. G. Lawless and colleagues obtained similar results in a genetic analysis of 80 nestlings from 23 broods of the highly territorial Eastern Screech-owl in Kentucky. In another detailed study, C. Rohner found that movement patterns of unpaired "floater" Great Horned Owls in Yukon Territory, Canada, did not change during the fertile period of females, though they would be predicted to do so if male floaters were seeking copulations with paired females. Extra-pair copulations are equally unknown in the well-studied Spotted Owl.

Eight species of Strigidae are known to be polygamous. In other bird families, polygamy is commonest in situations where the adults, especially adult males, take little or no part in the feeding of the young. In owls, however, the males are the primary providers of food for the female and the young, so polygamy is restricted to times of prey abundance. Polygamy occurs most often in species that specialize on microtine rodents as prey, because voles exhibit dramatic population explosions every three to four years. In those years, some males find it relatively easy to provision the female and young at more than one nest, so such a male will try to attract a second female to his territory once his first (primary) female is incubating a full clutch of eggs.

Polygamy has been documented in the Eurasian Scops-owl, Snowy, Tawny and Ural Owls, Northern Hawk-owl and Northern Long-eared Owl, but it is probably commonest in the Boreal

While the diurnal lifestyle of many reptiles means that they frequently avoid the predations of owls, lizards and snakes nevertheless do form a small proportion of the diet of a fair number of strigids, most notably those of the genera Otus, Bubo, Strix and Glaucidium. In South-east Asia, geckos are particularly abundant and are often active at night, so it is hardly surprising that a Sunda Scops-owl should take advantage of such a relatively easy meal. Here, the unfortunate victim is of the species Gehyra dubia.

[*Otus lempiji cnephaeus*, Singapore.
Photo: Morten Strange]

Larger reptiles, including snakes, also fall victim to owls on occasion. Although the Buffy Fish-owl feeds mostly on fish, its diet includes a wide variety of other animals, ranging from frogs, small mammals and birds to reptiles and insects. As this photograph shows, it is not averse to killing and eating snakes, but it is doubtful whether such prey ever form a significant part of this species' diet. It would be interesting to determine just how many snakes are taken by strigids living in desert habitats, where these reptiles are largely nocturnal.

[*Ketupa ketupu ketupu*, Kuala Selangor Nature Park, Malaysia.
Photo: Arnoud B. van den Berg]

Among the most specialized of the Strigidae are the fishing-owls of the African genus *Scotopelia*. The largest of these, Pel's Fishing-owl, is also the best studied of the three species.

It is known to take some amphibians and freshwater crustaceans, as well as larger insects, but by far the majority of its food consists of fish in the size range 100-200 g, though with some weighing up to 2000 g.

This very big owl frequents the forested edges of rivers and lakes, where it hunts, mainly at night, from a perch 1-2 m above shallow water.

It probably detects fish from the surface ripples they create, following which it glides down to snatch the prey from the surface. Catfish are very commonly captured in this way. Like their Asian counterparts, the fish-owls of the genus *Ketupa*, the *Scotopelia* owls have unfeathered tarsi and toes, and the soles of their feet are equipped with spiny scales, adaptations that enable them more easily to grasp their slippery piscine prey. Being largely dependent on fish, Pel's Fishing-owl breeds when water levels are low, conditions which facilitate the capture of these aquatic prey.

Of course, fluctuations in water levels occur periodically, and in periods of drought or, conversely, flooding the owl is often forced to move to nearby areas where conditions are better for it.

In most cases, strigids use their talons to capture prey. Insects, such as orthopterans, are often taken on the ground, the owl grasping them with one foot. The bird generally then uses the same foot to transfer the food directly to the bill for consumption. This method of food transference is very reminiscent of the way in which parrots (*Psittaciformes*) deal with their food. Here, a Burrowing Owl shows how it tackles a grasshopper.

[*Athene cunicularia hypugaea*, Grasslands National Park, Saskatchewan, Canada. Photos: Stephen J. Krasemann/DRK]

and Northern Saw-whet Owls. In these species, the usual form of polygamy is bigyny, where one male is paired with two females simultaneously. This has been particularly well studied for the Boreal Owl, in which 9-14% of breeding males are bigynous in years of peak vole numbers. A bigamous male attracts a primary female to a nest cavity and feeds her at a high rate during the egg-laying and copulation periods. After the clutch is complete, the male reduces the rate at which he feeds the primary female and begins singing again, usually near a suitable nest-site some distance from the primary nest cavity. If he succeeds in attracting a second female to this new nest-site, he feeds her at a high rate until she, too, completes a clutch. Despite the difficulty in feeding extra young, bigamous males raise more offspring than monogamous males. After provisioning their secondary females with food during egg-laying, the males turn their attention back to the primary brood, and feed the secondary female and her young only if the first brood is well fed. Primary females lay more eggs than the average monogamous female, and raise as many or more young. Secondary females, however, raise relatively few young on average because of higher nestling mortality while the male is attending to the primary brood. Because their nests are some distance from the primary nest, it is generally assumed that secondary females are deceived by the male and do not know that he is already paired when they choose him as a mate. This could hardly have applied, however, in the case of one particular male Northern Saw-whet Owl, which was found to be attending primary and secondary nests only 15 m apart.

At least two instances of trigyny have been documented in strigids. J. S. Marks and associates found a male Northern Saw-whet Owl in Idaho, USA, that was paired with three females simultaneously: two of the nests fledged young successfully, but the eggs failed to hatch at the third nest. During a food-addition experiment, B. G. Carlsson and B. Hörnfeldt noted an instance of trigyny in the Boreal Owl in Sweden, although it must be added that this might not have happened under more natural conditions. It should also be noted that all records of polygamy in cavity-nesting owls have occurred where researchers provided an abundance of nest-sites in the form of nestboxes.

A rarer form of polygamy in strigids is serial polyandry, in which a breeding female leaves her first nest-site and moves to a new territory to mate with a second male. The female deserts the nest late in the nestling period, when the young no longer require brooding, leaving the first male to continue to feed them alone. In normal situations, the female usually helps to provision the young in the later stages of the nestling period. Serial polyandry has been documented only in the Boreal Owl, but it probably occurs in the Northern Saw-whet Owl and perhaps in a few other species as well. Two interesting examples of mixed biandry and bigyny have been recorded in Boreal Owls. B. Kondratzki and R. Altmüller studied a bigynous male in Germany whose primary female left the nest to produce a second brood with a different male, and E. Korpimäki noted a female Boreal Owl in Finland whose second brood was the result of her being a secondary female to a bigynous male.

Most owls breed only once per season, presumably because the length of the breeding cycle and extended post-fledging care simply rule out any possibility of a second brood. However, double-brooding has been observed five times in Florida Burrowing Owls and once in the Northern Long-eared Owl. In the latter case, the event occurred during a year of high vole abundance. Whether this was another case of serial polyandry, as described above for Boreal Owls, or a rare instance of double-brooding by the same pair was not determined.

The timing of breeding among members of the Strigidae is keyed to prey availability and vulnerability. Mammal-eating species in temperate latitudes tend to nest in late winter or early spring; this is probably in order to take advantage of the long nights, so that more time can be spent hunting for food when the young are growing. Eurasian Eagle-owls usually lay eggs in February or March throughout most of their range from Finland to Morocco, probably using the lengthening days as a stimulus to initiate nesting. Populations of close relatives in tropical zones only slightly farther south seem to exhibit less seasonality in their breeding, although data are sparse. Insectivorous species nest later at temperate latitudes, so that food is abundant during the nestling stage. Eurasian Pygmy-owls seem to time their breeding so that the nes-

ling period coincides with the fledging times of many passerine species, which are important prey (see Food and Feeding).

Those owls that nest in tropical regions with marked wet and dry seasons breed in the dry season or toward the end of it, so that the young fledge early in the wet season. This is particularly important for insectivorous species, which many tropical owls are, because it enables them to take advantage of the increase in insect numbers that occurs during the wet season. Off the coast of Tanzania, the Pemba Scops-owl (*Otus pembaensis*) lays eggs from August to October, before the short rains begin. In South Africa and Madagascar, Marsh Owls breed in March and April, after the rains have produced a lush growth of grass that in turn provides cover for nesting and forage for their rodent prey species. Pel's Fishing-owls lay at the time of peak river flow, so that their young fledge when water levels have dropped and fish are concentrated.

Many owls are particularly reliant on small mammals whose populations are subject to dramatic cycles of abundance. These cycles are very noticeable in voles, lemmings and snowshoe hares (*Lepus americanus*). The most widespread and well-studied of these situations concern owls that feed primarily on voles, including the Northern Hawk-owl, Boreal Owl, Northern Long-eared Owl and Short-eared Owl. In these species, the proportion of adults breeding, the number of eggs laid, and brood sizes at fledging vary dramatically from year to year, depending on vole numbers. Because clutch size is dependent on the condition of the female during egg-laying, females are likely to lay large clutches if they are well fed because of high prey numbers.

A. Lundberg found that breeding frequency, clutch size, and production of young in Swedish Ural Owls varied with vole abundance. H. Pietiäinen and associates reported that only 24% of female Ural Owls bred during vole lows in Finland, but 76% bred during vole population peaks; moreover, the owls laid larger eggs and initiated egg-laying earlier during peak vole years. An interesting aspect of the breeding strategies used by Boreal Owls during different parts of the vole population cycle has been studied in Finland by H. Hakkarainen and E. Korpimäki. They found that older males that had probably experienced one full vole cycle reduced their rates of food-provisioning at the nest in the peak year of the cycle compared with their rates during the phase of increase, despite the fact that prey was more abundant during the peak; the males did this by reducing feeding rates in the second half of the

night. On the other hand, the provisioning rates of young, inexperienced males were highest during the peak year of the vole population cycle. Hakkarainen and Korpimäki propose that experienced males can predict that the survival of their young would be low after a vole peak, when prey numbers crash, whereas juvenile survival during the increase phase would be very high.

Similarly, B. M. Appleby and colleagues found that Tawny Owls appear to be able to predict summer vole abundance on their territories. Clutches laid in March on territories that would have a high number of voles in June produced a preponderance of female offspring. Female Tawny Owls, but not males, appear to gain future reproductive advantages from being raised under conditions of good food supply.

Some strigid species will not breed in areas without high vole numbers. Northern Hawk-owls are especially noted for this, appearing in an area, nesting for one to three seasons, and then disappearing. C. Rohner and co-workers point out, however, that Northern Hawk-owls breeding in North America are also highly dependent on juvenile snowshoe hares for food, so their breeding success is not simply tied to vole numbers. Another well-studied predator-prey system is that of Great Horned Owls and snowshoe hares. In northern Canada and Alaska, snowshoe hares have a dramatic ten-year cycle in which they are extremely abundant for two years, after which numbers crash to near zero; they then recover about seven years later, and quickly rebuild to reach a peak again. Rohner has found that all territorial Great Horned Owls breed during the peak years, breeding numbers are reduced in the year of the hare decline, and no breeding occurs in the second and third years after the decline. During peak hare years, survival of young owls is high, and many non-breeding "floaters" are present. In the year of the decline, most juvenile mortality occurs before the young disperse from their natal territories; these birds generally die of disease and predation rather than from starvation.

To attract a mate or to renew the pair-bond with his partner, a male owl generally begins vocalizing about a month before nesting begins. Males in the genus *Asio*, such as the Northern Long-eared, Short-eared and Marsh Owls, perform wing-clapping displays, slapping their wings together beneath the body as they fly. Marsh Owl pairs fly together in wide circles over their territory during courtship, and males of the closely related Short-eared

Although pellets are produced by a wide variety of non-raptorial birds, those ejected by owls are especially large and compact.

These packages of indigestible matter, such as bones and hair, are ejected at the daytime roost or the nest, and are often present in quantity at regularly used sites. They provide the principal source of information on the diet of owls, enabling prey species to be identified from skeletal remains. This Spectacled Owl was perched quietly at its day roost in forest; it then bent forwards to eject a pellet from the previous night's hunting. Owls normally produce one pellet per meal.

Owls do not construct a nest of their own. Instead, the vast majority breed in natural or artificial cavities, or in old nests of other birds, while some species regularly nest on the ground. Open nests are commonly used by *Bubo* owls, as well as by some species of *Strix* and *Asio*. These are usually old structures built by corvids or raptors, and typically consist of sticks and twigs. They are normally sited in a tree, but may also be on a cliff ledge or, as in the case of this Great Horned Owl, in a saguaro cactus. In most instances, old stick nests of other species are used by the owl pair for one year only, unlike hole nests, which are frequently reused in subsequent years. All breeding studies carried out on strigids reveal a strict division of labour in the roles of the sexes. The female performs all of the incubation and brooding duties, and she develops a single large brood patch for this purpose; the male provisions his mate at the nest during these periods, at least until the young are old enough to be left alone in the nest.

Owl perform dramatic courtship displays high in the air. Nest displays are important in many species. Male Boreal and Northern Saw-whet Owls call from prospective nest-sites while trying to attract mates. In many ground-nesting species, typified by the Akun and Spotted Eagle-owls, pair-bonding displays include ritualized scraping at the nest-site.

In essentially every owl species, courtship characteristically involves ritualized feeding in which the male brings prey items to the female, and she in turn usually makes begging calls and movements characteristic of young owls. The presentation of food to the female is often accompanied by wing- and body-movement displays by the male, before copulation takes place. Male Snowy Owls give a dramatic "Angel-display" with outspread wings when presenting food to the female, whereas male Northern Long-eared Owls raise and lower their folded wings and "buck" the body up and down. Allopreening seems to play an important role in cementing the pair-bond, as well as being a conspicuous part of the pre- and post-copulatory behaviour of many species, including the Eurasian Scops-owl, Eastern Screech-owl and Spotted, Little and Burrowing Owls (see General Habits). Copulations are usually reported to take place shortly after dark, but it is impossible to say whether this is a true reflection of owl biology or an artifact of the behaviour of human observers, who tend to be more observant early in the evening!

Few other bird groups, the caprimulgiforms being one possible case, show such an antipathy toward nest-building as do the strigids. This is especially remarkable considering the wide variety of nest-sites used by owls. Some medium-sized and large species, such as Great Horned, Great Grey and Northern Long-eared Owls, prefer to use large stick nests built by other birds, especially corvids and hawks, but they will nest in almost any suitable situation, including cliff ledges and the tops of hollowed-out snags. In southern Africa, Spotted Eagle-owls often nest on the ground, but they also use nests built by Hamerkops (*Scopus umbretta*), hawks, eagles, corvids and Social Weavers (*Philetairus socius*). Verreaux's Eagle-owls, too, use Hamerkop nests, as well as those of storks (Ciconiidae), ibises (Threskiornithidae) and

buffalo-weavers (*Bubalornis*). White-faced owls have commonly been considered members of the genus *Otus* (see Systematics), but their habit of using stick nests built by other birds, rather than nesting in tree cavities (as do *Otus*), was one of the clues that resulted in their placement in *Prilopsis*. Southern White-faced Owls will use the larger stick nests mentioned above, but they also use smaller nests such as those built by pigeons (*Columba*), turacos (*Tauraco*), sparrows (*Passer*), waxbills (Estrildidae) and Wattled Starlings (*Creatophora cinerea*). Large squirrel dreys are used as nest-sites by many owl species around the world.

The very large Eurasian Eagle-owl usually nests on cliff ledges, but will use corvid and hawk nests if cliff sites are unavailable, and in northern Europe it will also nest on the ground next to trees. One female in Finland dug out cavities in large anthills, one of the few examples of actual nest construction in the Strigidae. Most Eurasian Eagle-owls simply remove sticks and loose stones to form a clean nest scrape.

Some owls, particularly those found in open country such as tundra and grassland, prefer to nest directly on the ground. The Striped, Short-eared and Marsh Owls nest in areas of tall grass, trampling down the stalks to form a nest platform of sorts. Owls that breed in shrubby habitats also nest on the ground, and these include the Laughing Owl of New Zealand and the White-browed Hawk-owl of Madagascar.

Smaller species of owls, such as those in the genera *Otus*, *Glaucidium* and *Aegolius*, generally nest in tree cavities that have been excavated by woodpeckers, a requirement that often makes the availability of nest-sites a limiting factor to these species (see Status and Conservation). G. D. Hayward has found that Boreal Owls in Idaho usually nest in cavities built by the Pileated Woodpecker, which often means that they must breed at lower elevations where the woodpecker is common, some distance from the owls' preferred foraging habitats at higher elevations; in Europe and Asia, this owl shows a similar reliance on the holes created by a related woodpecker species, the Black Woodpecker (*Dryocopus martius*). Some scops-owls are more adaptive, nesting in a wide variety of cavities: one African Scops-owl used a

Natural cavities in trees are among the most frequent nest-sites used by strigids, and are very typical for the smaller species. Such sites are regularly adopted by a large number of species of *Otus*, and also by many *Strix*, *Glaucidium* and *Athene* owls. The hollow interior of a broken-off limb offers a relatively secure and warm environment in which a Spotted Owlet can rear its young.

[*Athene brama indica*,
Ranthambore
National Park, India.
Photo Günter Ziesler]

recess in the side of the large stick nest of a Lappet-faced Vulture (*Torgos tracheliotus*). Larger owls in the genera *Strix*, *Ninox* and *Pulsatrix* nest in cavities that form in old trees where large branches have broken off, or where the trunk itself has broken, and Spotted Owls also utilize large clumps of tree branches formed in conifers by the action of dwarf mistletoe (*Arceuthobium*). Some

small strigids, such as the Western Screech-owl and Pallid Scops-owl, will use Black-billed Magpie (*Pica pica*) nests if tree cavities are not available. Cavity-nesting owls bring no other material to form the nest, although female Eurasian Pygmy-owls apparently clean out the nest-hole.

The Burrowing Owl is unique within the family in using underground burrows for nest-sites. Most of these are dug by fossorial mammals such as prairie-dogs (*Cynomys*), viscachas (*Lagostomus*) or badgers (*Taxidea*). The owls clean and enlarge some of the burrows, and there is some evidence that they can dig their own burrows if the soil is very sandy, especially in Florida and on islands in the West Indies.

Because owls do not build their own nests, they often accept man-made nests of varying types. Most, if not all, cavity-nesting owls will use artificial boxes. Indeed, in Finnish forests, where the large trees favoured by Black Woodpeckers are rare, about 95% of Boreal Owl pairs nest in such boxes. Eurasian Eagle-owls readily nest in lean-tos built by foresters, or in similar structures built specifically for their use, and one pair used a hide built by a nature photographer to view displaying Western Capercaillies (*Tetrao urogallus*)! A Spotted Eagle-owl once nested on a geranium box set outside the bedroom window of a house, and Great Grey Owls will nest on wooden platforms placed in trees in suitable habitats.

Nest sanitation varies from species to species. Members of the genus *Otus* tend to maintain very clean nest cavities and use the same hole year after year, whereas the cavity nests of many other species become fouled with faecal material and prey remains. Most owls that take over stick nests tend to use them for one year only, and the same applies to cavity-nesters in the genus *Aegolius*. Some researchers speculate that Boreal Owls change nest-sites every year because it lowers the risk of predation, but such changes could equally result from the cavities becoming filled with excrement and prey remains towards the end of the nesting period, rendering a new cavity more suitable than an old one. Some nestboxes have been used two years in a row by Northern Saw-whet Owls, but the boxes have been cleaned in the winter by humans, and the occupants in the second year were never the same pair as in the first year.

Owl eggs are pure white, and are usually round to oval in shape. Selection for spotted or otherwise camouflaged eggs is

A common practice among the smaller strigids is that of taking over old cavity nests of other species, especially woodpeckers (*Picidae*) and barbets (*Capitonidae*). A disused woodpecker hole in a sabal palm provides an ideal nesting site for a Cuban Pygmy-owl. In some parts of the world, particularly in the boreal region, certain species of owl appear to be heavily dependent on the existence of old woodpecker holes for breeding, to the point that the availability of such cavities is a limiting factor in their distribution and abundance.

[*Glaucidium siju siju*,
Ciénaga de Zapata, Cuba.

VIREO]

When it comes to exploiting the nest sites of other avian species, it is not only tree cavities that are used by strigids. Indeed, a rather wide variety of structures is made use of. In the Neotropics, for example, the oven-shaped mud nests of horneros (*Furnariidae*) are quite frequently used by several species of pygmy-owl. Here, a Ferruginous Pygmy-owl has made its home in the nest of a Rufous Hornero (*Furnarius rufus*), a common bird of open country, parks and even urban areas.

[*Glaucidium brasilianum brasilianum*,
Pantanal of Mato Grosso,

Although perhaps a somewhat incongruous sight, it is not that unusual for a Verreaux's Eagle-owl to use the colonial nests of weavers (*Bubalornis*, *Philetaurus*) as a platform for its own nest.

This adaptable and opportunistic owl will also nest at times on the top of the huge nest of a Hamerkop (*Scopus umbretta*), as well as in stick nests of storks (*Ciconiidae*), ibises (*Threskiornithidae*) and other large birds.

The distinctive pink eyelids of this owl are well visible in this photograph.

probably precluded by the facts that owls normally begin incubation shortly after the first egg is laid, and incubate their eggs continuously during the day. Conversely, white eggs laid in open nests may have promoted the early onset of incubation characteristic of most owl species. Round eggs are typical of cavity-nesting species, such as many strigids, because there is little danger that the eggs will roll out of the nest.

Egg size in strigids ranges from about 28 x 35 mm in the Elf Owl to 50 x 60 mm in the Eurasian Eagle-owl. Small insectivorous species, such as the Elf Owl and most scops-owls, tend to have small clutch sizes, normally 2-4 eggs, as do large carnivorous or piscivorous species in the genera *Bubo*, *Kenya* and *Scotopelia*. Species reliant on mice, voles and other small rodents generally lay larger clutches, 4-7 eggs on average, and they may lay clutches of up to nine eggs or more during periods of especially high prey abundance.

The eggs are usually laid at intervals of about two days, and incubation begins with the first or second egg. This, of course, results in nestlings of very different ages, particularly in the case of large clutches. For example, the oldest nestling in a brood of seven young would be about two weeks older than the youngest one. Asynchronous hatching has often been considered to be a brood-reduction strategy, so that, if food becomes scarce towards the end of the nestling period, the oldest, largest chicks will remain well fed, whereas the youngest and smallest often starve. Some cavity-nesting owls, however, such as pygmy-owls and the underground-nesting Burrowing Owl, tend to delay the start of incubation until most of the eggs have been laid. This suggests that the onset of incubation in owls is influenced more by vulnerability to predation than by the possibility of food limitation and subsequent brood reduction. This vulnerability to egg loss may be accentuated by the white, unmarked eggs of owls that nest in the open.

A strict division of labour occurs in all owls that have been well studied, with the female performing all of the incubation and brood-rearing duties, and the male doing all of the hunting, at least while the female is attending the nest. Incubation periods range from 22 days in small species, such as the African Scops-owl, to 32 days in larger species, such as Verreaux's Eagle-owl. Female strigids develop a single large incubation patch in the centre of the abdomen, and in most species the female remains

on the nest from several days before egg-laying begins until the time when the young are old enough to maintain body heat on their own. Females generally leave the nest only once or twice each night to defecate and cast pellets, and they do not begin to hunt for themselves until later in the brood-rearing period; indeed, in species such as the Northern Saw-whet Owl, the female is so heavy during egg-laying, reaching 150% of her normal mass, that she can fly only very laboriously. In the Boreal Owl, the female helps the male feed the young after she stops brooding, but the male continues to be the primary food-provider for the young. Female Southern Boobooks will help provision the young for two or three weeks after fledging, but the male then continues to feed them alone until they become independent about six or seven weeks after they have fledged.

As mentioned earlier, males do all of the hunting and provide all of the food for the female and young, at least for the first two or three weeks of the nestling period. The male usually calls when arriving with food, often with a subdued or shortened version of the advertising song. The transfer of food from the male to the female usually takes place at the nest, but in some species, particularly pygmy-owls, the male calls and the female leaves the cavity, takes the food, and then returns to the nest to feed the young herself. While the young are small, the male delivers the prey item to the female, and she tears it into smaller pieces for the nestlings. As the young become older and are able to feed themselves, the male may simply drop prey items at the nest without transferring them to the female. In Northern Saw-whet Owls, when the young are old enough not to require brooding, the older owlets may feed bits of prey to their smaller siblings.

In smaller mouse-eating strigids, such as *Glaucidium* and *Aegolius* species, the male often eats the head of the prey for his meal and gives the body to the female. Males of the much larger Great Grey Owl often eat whole mice themselves and carry bigger prey, such as pocket gophers, to the nest for the female and young, thus reducing the number of trips to the nest and associated flight costs.

In many species, for example the Eurasian Scops-owl, Pel's Fishing-owl, Great Grey Owl, African Wood-owl, Northern Long-eared Owl and Short-eared Owl, most of the defence of the nest is undertaken by the female, perhaps because she is usually alone at the nest-site, and because she is the larger sex. If the

Some species of owl nest on the ground as an alternative to using an elevated site, but certain species, mainly those inhabiting open country, are habitual ground-nesters. The latter are typified by the genus *Asio*, the best-known member of which is the widespread Short-eared Owl.

This medium-sized owl breeds in grassland, moorland, tundra and other open habitats, and invariably nests on the ground, in this instance among tall heather (*Calluna vulgaris*) on open moorland. The owl tramples down the vegetation stalks to form a platform, usually lining this with some grasses and downy feathers; of great interest is the fact that this species, at least in Europe, seems to make some effort to build a nest, behaviour almost unique among the *Strigidae*.

The eggs of all owl species are white and unmarked, and generally rounded to oval in shape; they are normally laid at intervals of two days, with incubation beginning with the first or second egg. A fascinating aspect of clutch size is that, among rodent-eating owls living in areas where their prey are subject to cyclic fluctuations, the number of eggs laid varies annually in accordance with prey abundance. Short-eared Owls in northern regions lay about 4-5 eggs in years with low populations of voles, but up to 10 eggs in peak vole years. In years when cyclic rodents are at extremely low levels, some owls may not attempt to breed at all.

male is present, he may join in nest defence or simply hoot from his roost nearby. Female Southern White-faced Owls threaten nest intruders with their talons and by snarling; the male then joins in the defence with diving attacks. In other species, for example the African Scops-owl and the Boreal Owl, the male often roosts several hundred metres from the nest and is usually unaware of any danger to it in the daytime; at night, however, male Boreal Owls actively defend nestlings from predators. In contrast, male Snowy Owls apparently defend the nest vigorously when the young are small, diving on intruders and driving them away; when the young are larger and the female can leave without fear of their becoming chilled, she takes over most of the nest-defence duties, dramatically feigning injury to lead the predator away from the nest. Male Eastern Screech-owls defend nestlings more vigorously than do females; as in the case with Snowy Owls, perhaps the smaller, more agile males are more adept in aerial attacks on possible nest predators.

Females of some cavity-nesters, such as the Pearl-spotted Owlet and the Western Screech-Owl, flatten themselves on their eggs when disturbed at the nest. This behaviour presumably reduces the chances that the nest will be discovered by predators, but it exposes the incubating female to the risk of being killed in the cavity by the predator. Other species, such as Flammulated and Northern Saw-whet Owls, typically fly from the cavity before the intruder reaches the nest. Females of some of the open-nesting species, such as the Northern Long-eared and Short-eared Owls, characteristically defecate on their eggs when flushed from the nest by an intruder. Whether this behaviour is an attempt to make the eggs less appealing to predators, or is simply a consequence of the female having stored up a large amount of faeces while sitting on the nest, remains to be determined.

It is worth repeating that females of some species, notably Great Grey, Ural and Snowy Owls, once their young have hatched, can be extremely fierce when the nest is approached by a human

being; although the degree of hostility varies individually, some females will launch an attack when the intruder is still about 100 m away, and they are capable of inflicting very serious injury. Even after the owlets have left the nest, it is unwise to attempt to get too close to these owls.

Young *Aegolius* and some *Glaucidium* have their full juvenile plumage, and are reasonably adept at flying, as soon as they leave the nest cavity. Other young owls tend to leave the nest when still covered in down and unable to fly. Young Great Horned, Great Grey, Northern Long-eared, Short-eared and Marsh Owls typically move away from the nest, hopping or walking along adjacent branches or on the ground; these "branchers" enjoy high survival, and the move from the nest probably reduces the risk of predation. Young scops-owls and screech-owls are similarly downy and poor fliers when they leave the nest cavity, and they stay close to the nest-site for the first few days. Flammulated Owls can only glide when vacating the nest, but subsequently they can gain altitude by climbing up tree trunks, using the bill and feet.

In their study of the last-named species, B. D. Linkhart and R. T. Reynolds found that a brood would leave the nest over two consecutive nights. Within three days of the first young leaving, the brood had separated into two clear groups, one being fed exclusively by the male and the other by the female; the young in each group were those that left the nest on the same night. By dispersing young over a larger area, brood division may reduce predation in much the same manner as does "branching". No other direct evidence exists for brood division in owls, but very few studies have examined behaviour during the post-fledging period. J. R. Belthoff and G. Ritchison found no evidence that Eastern Screech-owls divide their broods, and J. Olsen and S. Trost determined that fledged broods of Southern Boobooks were fed by both parents for two to four weeks until the male took over all care.

For few owls has the fledgling period been studied, because of the difficulty of following individuals without using radio-telemetry.

During incubation, the female owl sits tight, leaving only occasionally, and for very brief periods, in order to defaecate and to eject pellets. Throughout this time she is fed on the nest by her mate, who is responsible for all the hunting during this stage of the breeding cycle, as well as during the brooding stage, which is also carried out by the female. Here, a male Great Grey Owl is feeding his incubating partner on the nest.

Only limited information is available on the copulatory behaviour of the great majority of strigids, and for many nothing is known. It is thought that most copulations take place shortly after dark, but this probably does not apply to all species; moreover, the difficulties of observing and recording such activities at night are self-evident. Copulation is preceded by the male offering food to his partner, the latter usually making begging calls and movements similar to those of young owls. This pair of Brown Fish-owls is just about to mate.

Helmut Denzau]

The Flammulated Owl fledglings mentioned above became less dependent on the adults about three weeks after leaving the nest, and left the territory about one week after that, in late August. Juveniles of the larger species, such as the Spotted Eagle-owl, are dependent on their parents for a much longer period of time, perhaps as long as five months. The reasons for this long-term dependency are not clearly understood, but such periods may be important in long-lived species that hunt challenging prey. Studies of Eastern Screech-Owls have shown that juvenile dispersal is controlled by intrinsic factors, a "natal restlessness" similar to the migratory restlessness experienced by migrating birds. Parental aggression is apparently not important in the initiation of dispersal. Recent work on Eastern and Western Screech-owls by J. R. Belthoff and A. M. Dufty suggests that the steroid hormone corticosterone is the proximate mechanism that triggers such dispersal.

Large owls that are resident on the same territory throughout most of their lives tend to be long-lived. One Great Horned Owl survived almost 28 years in the wild, and Eurasian Eagle-owls also live longer than 20 years, whereas Barred and Tawny Owls have been known to live for more than 18 years in the wild. Medium-sized nomadic or migratory species such as Burrowing, Northern Long-eared and Short-eared Owls have much shorter life expectancies, more of the order of five to nine years, although one exceptional Northern Long-eared Owl survived for 27 years and 9 months. Western and Eastern Screech-owls have been known to live about 13 years; although small, both species are non-migratory. Small nomadic or migratory species such as Elf Owls and Northern Saw-whet Owls have the shortest natural lifespans, only four to seven years. In captivity, however, many of these owls can live much longer. For example, a captive Northern Saw-whet Owl died at the impressive age of 16.

Movements

The vast majority of owls show no patterns of movement outside their normal home ranges, other than juvenile dispersal. Fewer than 20 species, less than 10% of the Strigidae, have truly migratory populations, and in only half of these species is migration undertaken by a significant number of individuals. Nonetheless, owls demonstrate most of the strategies shown by birds, from

permanent residency to sporadic wandering or nomadism, partial migration and full migration. Migratory individuals move after the breeding season to a separate wintering ground, then return to the same breeding area in the following year. No species of owl, however, is completely migratory, where the entire breeding range is vacated in winter. Insectivorous species make up the bulk of true migrants, whereas species that specialize on cyclical rodent populations tend to undertake irregular nomadic or irruptive movements.

The few insectivorous owls that breed in northern temperate regions have fully migratory populations. For example, northern populations of the Brown Hawk-owl migrate from northern China, eastern Russia and Japan to Indonesia and the Philippines. They return to Japan each May, where they are the commonest owl in that country during the summer months, subsisting on a diet dominated by invertebrates.

The migratory pattern of the Oriental Scops-owl is similar, with northern populations moving from Mongolia, eastern Russia, northern China, Korea and Japan to wintering grounds in southern China and South-east Asia, where they mix with resident populations of the same species. Migrants often collide with lighthouses in the Straits of Malacca while flying from the Malay Peninsula to Sumatra. Apparently, there are only two confirmed records of the Oriental Scops-owl wintering in Sumatra, and none from Kalimantan, but individuals have landed on ships in the South China Sea, indicating a migratory path between Indochina and Borneo. Wintering numbers in Indonesia may be larger than the available data suggest, because these small owls would be very difficult to detect in forested wintering habitats, especially if not calling.

Similarly, there are extremely few winter records of the Flammulated Owl, a common species that breeds throughout the western cordilleras of North America north to central British Columbia, but retreats in winter to the pine-oak forest of Mexico and northern Central America. This lack of winter records led one ornithologist to suggest that this owl is able to spend the winter in a state of torpor, just like the similar-sized caprimulgid, the Common Poorwill (*Phalaenoptilus nuttallii*). Subsequent studies on the physiology of these owls, however, have ruled out this interesting possibility, so the difficulty of finding a small, silent, nocturnal owl in a relatively unexplored region is more likely the reason for the lack of winter records of Flammulated Owls.

One of the better-studied owls is the Little Owl, here shown copulating. The male of this species usually utters a brief call to attract the female for copulation, following which he may bob up and down in front of her before mounting; the female may crouch and shiver her wings, or the male may simply mount her without any preamble. During copulation, the male often grabs his partner's head feathers in his bill, while she holds her body in a horizontal posture. Copulation itself is brief and lasts only a few seconds, before the male dismounts. Allopreening appears to be important in the pre- and post-copulatory behaviour of many species, including the Little Owl, and it also serves to cement the pair-bond.

The Flammulated Owl's close relative, the Eurasian Scops-owl, migrates from Eurasia across the Sahara to central Africa, although some birds remain year-round in the Mediterranean area. Migration of individuals from higher latitudes is also illustrated by the Austral Pygmy-owl, whose breeding populations in southern Argentina move north in winter to sites in the northern half of Argentina. Similarly, the southernmost populations of the Southern Boobook show at least a partial migration to warmer areas of northern Australia in winter.

Migration patterns of other strigids are often obscured by the fact that the more northerly or, as is the case with one or two Southern Hemisphere examples, the more southerly breeders migrate to wintering areas already occupied by resident populations of the species concerned. The wintering grounds of Burrowing Owls breeding in the northern USA and southern Canada have long been a mystery. The birds move south in October and return in March and April, but, because they mix with resident populations in winter, it has been difficult to determine their whereabouts in that season. Recent radio-telemetry studies of Burrowing Owls that breed in the Canadian province of Saskatchewan have found a few birds wintering on the south coast of Texas and adjacent areas of north-eastern Mexico.

Perhaps the most migratory of owls, at least in terms of the proportion of the breeding population leaving the breeding grounds each year, is the Snowy Owl, which nests on Arctic tundra throughout much of the Northern Hemisphere. Most Snowy Owls leave their breeding territories each autumn, spending the winter in the taiga and plains of Eurasia, Alaska and Canada. A few individuals, reputedly adult males, winter within the breeding range, although the number probably varies widely from year to year. Snowy Owls also exhibit nomadic and irruptive movements. The variation in these movements is illustrated by three siblings ringed in 1960 in a nest on Victoria Island in the Canadian Arctic: one was recovered in October 1961 in eastern Ontario, Canada; another was found in May 1962 on the Hudson Bay coast; and the third was found in February 1962 on the island of Sakhalin in eastern Russia.

P. Kerlinger and M. R. Lein have studied these movements in North America and concluded that some, if not most, North American Snowy Owls migrate each year to winter on the Canadian prairies and, to a lesser extent, the northern Great Plains

of the USA. Wintering numbers west and east of the prairies are much more irregular: on the Pacific and Atlantic coasts, large numbers are found only in irruption years, with a preponderance of first-year birds. Populations on the Canadian prairies are dominated by adults, and immatures predominate farther south in the north-central USA. Among the birds regularly wintering in central North America, Kerlinger and Lein found that adult females remained farther north than the other age and sex classes, whereas immature males wintered the farthest south. They hypothesized that the large adult females were able to displace other birds and maintain winter territories closer to the breeding grounds through social dominance. How this situation relates to reports that adult males are more likely to remain on the breeding grounds is unclear.

Northern Hawk-owls are vole specialists, and breeding populations show distinct patterns of nomadism, vacating large areas in one year to breed in other areas of higher vole density in the next. After a peak in the vole population, the numbers of these owls can be very high in some areas. When vole numbers crash, the owls move out *en masse*, going south or to lower elevations in search of prey. I. Byrkjedal and G. Langhelle studied these classic irruptive movements in Norway, and found that adult females were much more likely to leave their breeding areas than were other age-sex classes, whereas adult males were more likely to remain on the breeding grounds. These movement patterns of males and females are more or less the opposite of those found in Snowy Owls, probably because it is advantageous for male Northern Hawk-owls to remain close to breeding territories that contain scarce tree cavities for nest-sites.

A proposed relationship between prey specialization, nest-site scarcity and migration strategy was put forward by A. Lundberg, who noted that owls specializing on small mammals with cyclical populations are more likely to be migratory or nomadic, whereas those nesting in scarce tree cavities are less likely to leave the breeding grounds. Thus, Snowy and Short-eared Owls prey on voles or lemmings, nest on the ground, and show a high level of nomadism, whereas Ural and Barred Owls have broader feeding niches, nest in large tree cavities, which are scarce in their breeding ranges, and are year-round residents on their territories. Boreal Owls, which nest in tree cavities and feed on voles, show an intermediate pattern, with adult males remaining on the

Once the chicks have hatched, the female owl broods and protects them continuously until they are big enough to be left on their own for short periods without the risk of losing too much body heat. She tends them with great care, feeding them with items delivered by the male. In many strigids, including the Short-eared Owl, the defence of the nest is undertaken largely by the female; as she is usually larger than the male, and is frequently alone at the nest, this is perhaps not surprising. The male occasionally assists if he happens to be nearby, but male Short-eared Owls can also be very aggressive towards intruders, making diving attacks and sometimes drawing blood.

[*Asio flammeus flammeus*, Great Britain.
B. Speake/Aquila]

breeding territories all year round and females and young birds dispersing from their breeding and natal areas, respectively, at least during years of vole scarcity.

The dispersal and migration strategies of Boreal Owls have been well studied in Germany and Finland. Prey populations in Germany are much more stable than those in Finland, where vole numbers are highly cyclical. Boreal Owls in Germany, therefore, tend to remain on the breeding territories throughout the year, whereas those in Finland are much more prone to leave their territories after breeding during periods of low vole numbers. Female Boreal Owls from both areas move more often between breeding seasons, and travel longer distances, than do adult males. Because the smaller, more agile males can probably catch a wider range of prey, they can make a living on their breeding territories even when vole populations are very low.

The Northern Saw-whet Owl is another species with a partial-migration strategy. This species winters throughout its breeding range, but considerable numbers of individuals from northern populations move south in winter, some covering thousands of kilometres from central Canada to the central USA. Each year, between 2000 and 5000 of the owls are ringed at trapping stations in the USA. In most years, the bulk of this movement applies to young birds, but many adults migrate as well. Populations migrating along the Atlantic coast of the USA are dominated by juvenile females, and adult males are the least common age-sex class encountered. Ratios of juveniles to adults vary from 10:1 in irruptive years to 1:4 in years when few birds migrate. Some individuals have been recaptured at the same ringing stations in subsequent years, suggesting that the same migration routes are used regularly by some owls.

Northern Long-eared Owls have a stronger tendency to migrate out of northern breeding areas than do Boreal and Northern Saw-whet Owls. They are probably more sensitive to snow depth than the latter two species because they prefer to hunt over open fields, which are more prone to accumulate snow than are the forests where Boreal and Northern Saw-whet Owls search for prey. Their favourite nest-sites, stick nests built by corvids and hawks, are probably more readily available than are suitable tree cavities, so there is less pressure for male Northern Long-eared Owls to remain on territories at the northern edge of the species' range.

The seasonal movements of owls that breed in mountainous areas are often vertical (in elevation) rather than latitudinal. In winter, Great Grey Owls in Oregon, USA, move to lower elevations that have less snow than their breeding territories and, also in western North America, Northern Pygmy-owls routinely move from montane forest to valley bottoms, where they feed on passerines that congregate in winter at suburban bird-feeders. Conversely, Spotted Eagle-owls in Malawi move to higher, cooler elevations during the hottest months of the year.

Owls with nomadic habits often fly large distances, sometimes hundreds of kilometres, to new breeding sites, usually when prey populations at their previous sites have crashed. Snowy Owls, Northern Hawk-owls and Short-eared Owls are good examples, but Great Grey, Boreal, Northern Saw-whet and Northern Long-eared Owls also have nomadic tendencies. When vole populations crash in the northern forests, Great Grey Owls abandon their territories and wander widely in search of better hunting conditions; the female of a pair will usually move first, then the male too if conditions remain poor. Similarly, of 23 Boreal Owl males studied in Finland by E. Korpimäki and associates, most moved less than 1 km and none moved more than 5 km between breeding sites, whereas half of the adult females moved more than 4 km and one shifted 580 km. Southern White-faced Owls and Marsh Owls are also somewhat nomadic in the drier parts of their ranges, appearing in numbers after rains have produced an abundance of prey and, in the case of Marsh Owls, tall grass for nesting. Pel's Fishing-owls make irregular movements, stimulated by droughts that render their breeding territories unsuitable.

Nomadic species also have irruptive tendencies: not only do they wander widely in search of good foraging areas, but they also periodically invade regions in large numbers. Often, these latter areas are not part of the species' normal breeding or wintering range. This phenomenon is generally thought to result from high populations produced during times of prey abundance, usually related to the vole population cycles in northern forests. When prey populations plummet, the large number of young owls produced during the vole peak, and many of the adults as well, are forced to disperse to find food. A dense population of Short-eared Owls studied by A. Village dispersed widely after a significant spring decline in vole numbers in southern Scotland; an adult male was found dead in southern England in November, and in

This male Snowy Owl, having succeeded in catching a large rodent, is delivering it to the female, so that she can prepare to pass the meal to the nestlings. When the young owls are older and able to manipulate sizeable prey themselves, the male may drop food items at the nest, or even transfer them directly to the young.

In the case of species which nest in tree holes, the young, when old enough to stand comfortably, will come to the entrance of the hole to receive food from the arriving parent. These young African Wood-owls are well advanced in their growth and development, and are able to stand at the opening of the nest to take prey items from the incoming adult. The latter generally announces its imminent return with a special call, recognized by the owlets.

[*Strix woodfordii woodfordii*, Somerset West, Western Cape, South Africa. Photo: J. J. Brooks/Aquila]

December an adult female was shot in Spain, 1730 km south of its breeding territory. In the following spring, others from the same population appeared farther north, in the Shetland and Orkney Islands. A juvenile male Northern Long-eared Owl, dispersing after a vole crash in Saskatchewan, Canada, was killed in Oaxaca, Mexico, in the same year, having made a journey of almost 4000 km. Two others of that species ringed in the USA, one in Minnesota and the other in Montana, were recovered in Mexico more than 3000 km from their respective ringing sites.

Of course, juvenile dispersal is characteristic of all strigids. Distances covered are relatively short in some species, but they can be very long in others. Juvenile Spotted Owls in New Mexico, USA, dispersed over distances ranging from 1.3 km to 145 km, some crossing wide areas of unsuitable habitat to different mountain ranges. J. R. Belthoff and G. Ritchison found that Eastern Screech-owls in Kentucky dispersed up to 16.9 km from their natal territories, with a median value of 2.3 km, but the authors were unable to differentiate the sexes in their sample. In Finland, however, E. Korpimäki and associates found that juvenile female Boreal Owls dispersed farther than did juvenile males, with median values of 80 km and 20 km, respectively. Of 189 Northern Long-eared Owl fledglings ringed by J. S. Marks in south-western Idaho, four were captured as breeders a year later; all were males, and each bred successfully 50-1500 m from its natal nest, demonstrating that, even among "nomadic" species, juvenile dispersal can be exceedingly short in some cases.

Examples of what may be considered true vagrancy by strigids are understandably few. Nevertheless, Northern Hawk-owls of the North American subspecies *caparoch* have been identified in Britain and on the Canary Islands. In addition, there are several records of Eurasian Scops-owls and Boreal Owls in Britain, far outside the breeding range of either species.

Relationship with Man

Owls have held a special fascination over humans for thousands of years. With their large eyes positioned on the front of the head and, in some cases, with "ears" that appear to be in the right place, the strigid owls have a human-like quality that many people find irresistibly endearing. At the same time, however, the

human-like appearance of owls, combined with their nocturnal habits and haunting vocalizations, invoke fear and superstition among people of many different cultures. As a result, owls have been inseparably linked with death wherever they occur.

It is highly likely that owls were among the first birds to play an important role in the legends and myths of ancient man, probably because their vocalizations in the dead of night could have caused havoc in the superstitious mind. Because humans undoubtedly evolved in Africa, it must be there that the paths of owls and human beings first crossed; yet, the first "written" evidence of contact between humans and owls comes from Europe. Some 15,000 to 20,000 years ago, Upper Paleolithic people in southwestern France painted the first known owl interpretations on their cave walls. A simple rock painting, discovered in December 1994 in La Crotte Chauvet cave, illustrates an owl with ear-tufts, making it either a *Bubo* or an *Asio*, or perhaps an *Otus*.

At the Trois-Frères cave in the French Pyrenees, another ancient painting depicts a curious figure of a man with antlers. Experts in prehistoric art named it the "Sorcerer". The subject's erect posture identifies it as a human, but the rest of the body is a mix of non-human animal parts, including the head of a crow, the face of an owl, the ears of a wolf and the beard of a chamois. The "Sorcerer" is most likely a shaman who is performing a dance to ensure the success of an imminent hunting excursion. By depicting the face of an owl, the artist might have been striving to endow the hunter with excellent eyesight, especially in darkness.

Aboriginal cave paintings demonstrate that owls have fascinated humans for millennia in Australia, too. "Dumbi the owl" was the son of a Wandjina, which is a half-human spirit that Aborigines believe existed at the creation of the world. A long time ago, the young Dumbi was pulled from his nest by some boys, who tore off his feathers, maimed him with a stick, and threw stones at him. When he learned of the boys' cruelty, the Wandjina called in a voice like thunder and sent lightning and rain on the place. Many people drowned in the flood that ensued, which is why the children never touch owls today.

In other parts of Australia, owls were thought to guard the souls of women, a belief that gave them a measure of protection. Each woman believed that the lives of her mother, sisters, daughters and so forth, and equally her own life, were bound up with

A further example of the adult feeding its well-grown chicks directly is provided by this Little Owl at its nest in an old orchard. As with the passing of food from male to female, prey items are presented to the chick bill to bill. Several studies have revealed that the nestlings of this species can climb up to the nest entrance when about three weeks old, and that they receive frequent food deliveries from the parents. Young Little Owls, like those of many strigids, often venture outside the nest before they are capable of flight, which in this species occurs at 30-35 days of age.

[*Athene noctua vidalii*,
Warwickshire, England.

Aquila]

the lives of particular owls and that, in guarding the owl species, she was guarding the lives of her female relatives. In parts of Asia, the owl was considered a protector, a divine ancestor, who helped ward off evil spirits, famine and pestilence. In the Pacific islands of Samoa, people believed that they were descended from an owl, although it is not known which particular species their ancestor was supposed to have been.

The family name Strigidae, and the generic name *Strix* to describe a large number of species, suggest an undeservedly sinister reputation among owls in general. *Strix* is Greek for "witch", being transformed to *striga* in Latin; naturally there is no reason to believe that the 19 species of *Strix* are any more likely to be associated with sorcery than are the other owl species. Nevertheless, the conviction that all owls are linked with witchcraft has been widespread throughout the world.

In Sicily, for example, legend has it that, if a Eurasian Scops-owl called near the house of a sick man, he would die three days later. If nobody nearby was sick, then the owl's call announced that someone would be struck down with tonsil trouble. To the Chinese, owls snatched away souls, and their calls were referred to as "digging the grave". In the Arab world, it was believed that owls were the souls of people who had been killed. In Hispaniola, Stygian Owls were persecuted by local people who believed that owls had supernatural powers and could transform themselves into witches. Indian tribes living on the pampas of Argentina feared the Burrowing Owl, and their name for the species translated to "sister of evil"; reportedly, they killed every Burrowing Owl they encountered, and would not make camp in areas where these owls had nested. Elsewhere in American Indian culture, owls were thought to possess mysterious powers and were widely believed to presage the death of people who heard them and to bring illness upon people deserving of such fate. The Pima Indians of the south-western USA believed that the owl could safely guide them on their journey from life to death. By Pima custom, an owl feather was placed in the hand of one thought to be near death, in the belief that the owl would know that the person was ready to embark on the journey; the feather had to be one that was moulted by a living owl, and the Pimas collected such feathers whenever they found them. Indeed, Pima shamans sometimes kept live owls, taken as nestlings, for the purpose of building up a stock of appropriate feathers.

In Africa, especially, it is still commonly alleged that these nocturnal birds are possessed demons. Consequently, to see one is a sure sign of impending disaster, more so than walking under a ladder or seeing a black cat cross the road. Witchdoctors in West Africa are required to mingle their own blood with that of an animal during the blood-brother initiation. Although the bond is usually established with a ferocious creature such as a leopard.

A most interesting aspect of owl behaviour is demonstrated by this adult Morepork. Having returned to its nest with a tasty morsel of food, it does not offer this directly to its young waiting at the entrance. Instead, it perches very close by, attempting to encourage the owlet to leave the hole. The young of many species of strigid habitually leave the nest before fully fledged, and remain nearby in the surrounding branches; this behaviour, known as "branching", is thought to reduce the risk of the entire brood being preyed on.

[*Ninox novaeseelandiae*
novaeseelandiae,
Katikati, North Island,
New Zealand.
Photo: Brian Chudleigh]

Even after the young have left the nest, the parents' duties are far from over. The owlets remain dependent on their parents for several weeks or, in the case of larger species, even some months after they have fledged. Here, a female Austral Pygmy-owl is feeding a mouse to its offspring, which have clearly left the nest hole for the last time. Although the period of post-fledging care of this species is not known for certain, it is likely to be at least three weeks. During this time, the young owls will learn to catch their own food and to fend for themselves.

[*Glaucidium nanum*, Torres del Paine National Park, Chile. Photo: Günter Ziesler]

snake or crocodile, owls and other night birds are acceptable alternatives.

In South Africa, owls were believed to be sent by evil witchdoctors to kill people. Should an owl settle on a hut, it was regarded as a messenger of death; even if it merely screamed while flying over the hut, it was believed to be foretelling some misfortune to the inhabitants. Not surprisingly, people threw burning brands at the birds to drive them off. If the owl was caught, it was soaked in paraffin and set on fire, possibly to break the witchdoctor's evil spell. South African tribes maintained that one must not imitate the cry of an owl, lest one's blankets be burned. In Madagascar, owls were said to join witches as they danced on graves. If an owl was captured in West Africa, its claws were broken and it was otherwise mistreated in the belief that the witchdoctor who sent it would suffer the same pain; in Nigeria, the owl was so dreaded that people would not mention it by name, referring to it instead as "the bird that makes you afraid". Furthermore, in Morocco, small children were not allowed to play outside after dusk, because it was believed that an owl flying over would make them seriously ill.

Some cultures also have stories of man-eating owls whose diet consists primarily of small children. In parts of China and Malaysia, it has been held that owls are particularly partial to the blood of newborn babies, and several North American Indian stories tell of children being taken away and eaten by these birds.

Recent comparative studies into different parts of the world demonstrated that many more superstitions about owls still exist in Africa than in Central America. In Malawi, more than 90% of the 147 people interviewed connected owls with bad luck, witchcraft and death. In Costa Rica, however, only 4% of 162 respondents associated owls with bad omens, and an additional 3% listed them as "frightening". In Chiapas, in southern Mexico, 102 students between eleven and 20 years of age were interviewed in 1998, and 17.6% stated that owls are birds of bad luck; on the other hand, an equal percentage considered them to be beneficial. A British television survey similarly interviewed more than 300 people aged 15 and older about their animal likes and dislikes. When given a choice between the terms "frightening" and "non-frightening", 39% of the respondents considered owls to be frightening, 35% did not, and 26% preferred to view owls as neither.

One possible explanation for these strong superstitions in the twentieth century is that owls are frequently associated, correctly so, with cemeteries. For example, where heavy deforestation has occurred near villages in Malawi, graveyards are often the only wooded areas remaining in the landscape, so that owls, naturally, use them for breeding and roosting. As people encounter owls more and more often in such places, the belief that the birds are connected with death is reinforced. Elsewhere, strigids that inhabit old-growth and mature forest may be associated with sacred large trees in riparian gallery forest, near temples and in cemeteries. In India, the Forest Eagle-owl plays a major role in many legends and is said to be associated with Hindu cemeteries, which are often the only local bastions of old-growth forest with large trees and snags. Forest Eagle-owls, Brown Fish-owls and Brown Wood-owls (*Strix leptogrammica*) also inhabit gallery forest of *Ficus* near water-holes and streams in India, which are sacred temple areas. In a sense, then, many of these species serve as indicators of the religious value of a forest. It is likely that the Sunda Scops-owl has survived in Java only because of the ill omen or reverence it represents in Indonesian legends.

Superstitions die hard, and all too often they give rise to behaviour quite disproportionate to an alleged offence. In Malawi and in East and South Africa, 189 people interviewed had witnessed 51 killings of owls. They listed the reasons for the killings as follows: superstitious beliefs to avoid bad omens (27.5%); just for fun during hunting (19.6%); to be eaten as a relish (15.7%); because the owl made too much noise (11.7%); to make magic medicine (7.7%); because it was nesting too close to a house (5.8%); because of the association with witchcraft (2.0%); because the owl killed a hen, attacked first, entered a hospital, or was killed by a car (each 2.0%); and for reasons unknown (2.0%). The overall picture provided by this survey is that little mercy is shown to owls in much of Africa.

In other cultures, the owl has appeared on artefacts such as Peruvian Moche pottery jugs, and North American Indian pipes and shields, and in delicate Chinese and Japanese paintings. In the past, owl symbols were used simply as signs of good luck, but today they appear in connection with anything from reading glasses to computers. At least two professional football clubs in England use the owl logo. Cigar boxes made by the White Owl company feature a Snowy Owl and have become a familiar sight

A steady supply of food is of vital importance for growing owl chicks, and the majority of strigids therefore time their breeding to coincide with the period when their preferred prey animals are most numerous and most easily accessible. Many owls breeding in the far northern parts of the globe are to a large extent dependent on voles.

With abundant food at hand, the well-fed females are more likely to produce large clutches, and the resulting offspring will also have a greater chance of survival. A good example is provided by the Snowy Owl. Pairs of this species breeding on tundra are almost totally dependent on lemmings and other voles, both as food for themselves and as food for their young. This youngster has been presented with a Norway lemming (*Lemmus lemmus*), a staple dietary item of Snowy Owls in Scandinavia and throughout the range in which that rodent occurs.

When lemmings are abundant, the female owls will lay clutches of as many as eleven eggs, with high fledging success. In years when lemming populations crash, other voles will be exploited. In years when no vole species are available in sufficient number, however, the risk of expending a great amount of energy in breeding, only to fail because of an inadequate food supply, is so great that these owls will forgo all nesting attempts for that season.

in the USA. That same species has also been depicted on the \$50 note in Canada since 1988.

Since ancient times, owls have been regarded as symbols of wisdom. They have been portrayed on coins, medals and books, and have even been associated with libraries and universities. Perhaps the best-known example of this symbolism is that concerning the Little Owl and the Greek goddess of wisdom, Athene; in ancient Greece, Athene was allied with the sacred owl of Athens, which now carries the generic name *Athene*. A Little Owl was depicted on a coin in about 450 BC in Greece, where its name was virtually synonymous with money, and a Little Owl coin also was minted in conjunction with the 350-year anniversary of the University of Helsinki in Finland.

No self-respecting gift shop in the Western world is without a display of owls manufactured in a variety of materials, from shells, glass and metal to minerals, pottery, wood and even polished coal, and a number of businesses have adopted the bird as a company logo, believing it to be a sign of integrity and wisdom. Thousands of people have lately become "addicted" to owls and collect anything with an owl on it. Most of the "owl aficionados" live in Europe and the USA, but such people also abound in South Africa, Australia and Japan, and even less "westernized" places such as the Philippines and Fiji can claim a few avid collectors of owl souvenirs. Serious "owlaholics" admit that they sleep on owl sheets, hang their toothbrushes on owl-shaped stands, dry their hands on owl towels, cook with owl oven pads, and wear owl jewellery. Most collectors, however, merely accumulate owl figurines, carvings, statues and paintings, while matchboxes, greeting cards, stamps and postcards with an owl on them are also very popular collector's items.

Night-shift workers and those who love the night-time hours inevitably are known as "night owls", who spend their time "owling" around. In the light of this, it is interesting to note that in Italy, particularly in the city of Bologna, a policeman on the beat is known as a "*gufo*" owl, and all over Italy the word "*civetta*", which means small owl, is used to describe a police patrol car.

Ghostly forms and weird, hooting cries of owls have inspired conflicting emotions, ranging from terror to reverence. Directors of horror and action films often add the call of a Tawny Owl to soundtracks at tense moments, and with good reason: this species' call must surely be one of the most evocative sounds in nature for many people. In viewing movies, one could easily get the impression that Tawny Owls are common in the USA, al-

though they occur only in the Old World! Similarly, the rapid staccato song of the male Boreal Owl can be heard in many movies during night scenes filmed far outside the species' geographical range, and always in the wrong habitat!

Owls have even found their way into *haute cuisine*. The Creoles of Louisiana, USA, perhaps inheriting dishes from French cuisine, used to eat Barred Owls. The hunting of Snowy Owls for food or other purposes seems to have been an old tradition that continues to some extent among Eskimos, who describe these owls as "lumps of fat". During the last glaciation, large numbers of Snowy Owls were eaten and used for magical purposes. Cave deposits in France have yielded thousands of bones of this species, often representing hundreds of individuals, and up to 90% of all bird bones collected. Some restaurants in China still have owls on the menu as great delicacies; one such is near Dan Xia Mountain, from where the local people catch wild animals, including owls, which they sell to local restaurants in the city of Shao Guan. In Uruguay, the flesh of the Burrowing Owl is served as a delicacy to local people convalescing from illness, in the belief that it produces an appetite for other foods.

Not everybody finds owls agreeable from an epicurean standpoint, but parts of owls may be consumed in the conviction that they have magical powers. A general belief in Africa has been that eating an owl's eye improves night vision. In North Africa, it is said to be essential to know which eye to eat, for an owl sleeps with one eye closed and the other permanently "awake"; to tell which is which, the eyes must be placed in a bowl of water, where the sleepy eye will sink and the desirable one will float. In Morocco, suspicious husbands and fathers had a rather different use for owl eyes, and one that did not even depend on the co-operation of the wife or daughter: placing the right eye of a Eurasian Eagle-owl into the hand of a sleeping wife or daughter ensured that the woman would tell the man exactly what she had been doing during the day.

Rather than using the owl as lie-detector or eating it, South African Bantus had a saying that owl flesh is not eaten, for its body is full of scurf that causes it to smell as if it were dead. In a more mundane context, a traditional saying exists in Yorkshire, England, to the effect that nice owl soup, presumably in moderate doses, is an excellent remedy for whooping cough. "Owl's-egg soup" is commonly reckoned to be effective against epilepsy, the only snag being that it has to be prepared when the moon is on the wane. In addition, owl eggs are seen as an effective cure

The breeding success of owls depends on several factors, among them food supply, weather conditions and levels of predation. The Burrowing Owl, since it nests in underground burrows, would seem especially vulnerable to predation of its eggs or young. This species lays 6-11 eggs, so this particular adult, photographed with young at its nest-burrow entrance in Canadian grassland, can be considered to have achieved excellent fledging success on this occasion. As owls normally raise only one brood per year, failure can have a serious effect on the total population.

[*Athene cunicularia hypugaea*,

Having left the nest, juvenile owls feed avidly and, like the adults, swallow prey whole.

Mice can form a large part of the diet of the Northern Long-eared Owl and, with a good supply of these and similar rodents, the young fledgling grows quickly. This species can fly when about 35 days old, but is cared for by the parents until it is at least two months of age.

Parts of the downy mesoptile plumage are still visible on this juvenile, but will disappear by the tenth week or thereabouts.

for various kinds of excessive indulgences, notably that of heavy drinking, for which it is maintained that even one egg is sufficient to clear the head. Similar prescriptions claim that owl eggs cooked in wine for three days will cure the worst cases of drunkenness; this is easy to believe if the drunk himself boils the egg for three days.

Puerto Rican folklore states that the Puerto Rican Screech-owl feeds on coffee beans and that it can be used as a cure for asthma; the asthma cure must presumably involve eating the owl, but the source provided no details to that effect. Owls are also used as healing medicines in South America and Asia. In China, dried bodies of Collared Scops-owls serve as medicine for various illnesses, and such practices are even more prevalent in Korea, where large numbers of these birds are killed each year for this purpose. Thailand also has a large Chinese community, and body parts of owls feature in traditional Chinese medicine; many strigids, therefore, are destroyed for medicinal purposes in Thailand. In India, owls are used to treat various ailments such as nervous debility, body pain and similar problems. An old Indian belief was that the meat of an owl is a potent aphrodisiac, but in other places owl meat was thought to cause loss of memory or complete insanity!

The American hero of Alamo fame, Davy Crockett, was said to imitate the cry of the Barred Owl when hunting Wild Turkeys (*Meleagris gallopavo*), for the birds would invariably react by gobbling in response, thereby disclosing their whereabouts. The Ainu people of northern Japan, who also depended on hunting for their livelihood, used to drink a "toast" to Blakiston's Eagle-owl, which they considered to be a divine ancestor, before setting out on a hunting expedition.

Eurasian Eagle-owls, Tawny Owls and Little Owls are commonly used as decoys to catch corvids, and even songbirds, which are illegally shot for sport. Eurasian Eagle-owls have also been used as bait, fitted up with netting, to catch falcons and hawks, which are subsequently trained for falconry. Today, the technique has been brought up to date by bird-ringers and photographers interested in capturing or photographing mobbing birds that are

aroused by a live or stuffed owl. A Great Horned Owl tethered near a nest has been employed for catching Hen Harriers (*Circus cyaneus*) and Merlins (*Falco columbarius*), and a plastic decoy of that large strigid can be effective for netting Northern Long-eared Owls near their nests; as the parents swoop at the "trespassing" owl, they collide with mist-nets strategically placed around it. Even Ospreys have been caught using a captive Great Horned Owl tethered to a floating timber platform.

A couple from Queensland, Australia, have come up with a novel way of deterring cormorants from eating up their profits. The Butlers, who farm Australian prawns, have placed plastic owls around their property to keep away some 30 cormorants that regularly occur in the vicinity; they concluded that the owls protected the prawns, and even prescribed the treatment of two decoy owls per hectare of prawn pond. In North America, plastic decoy owls are widely used in attempts to keep Rock Doves from roosting on public buildings, although the doves invariably figure out the ruse in a short period of time. As a result, plastic owls bearing conspicuous white stains can be seen "perched" on roof tops and building ledges from coast to coast in the USA.

Some owls, especially Snowy and Short-eared, have become a problem at airports, where the relatively undisturbed fields surrounding such sites offer ideal habitats for mice and voles. Unfortunately, these same owls sometimes collide with aircraft, causing serious damage to engines although, so far (touch wood!), no fatal accidents. Luckily, trained eagles can be used to harass smaller birds, including owls, and thus help to prevent collisions with the planes.

The potential ability of owls, be they tytonids or strigids, to depress rodent numbers and other populations of pest species has been appreciated in many parts of the world. Farmers have built "owl holes" into the eaves of their barns and placed nestboxes in fields and forest to encourage owls to nest. In Kenya, tame owls have been used to hunt longhorn beetles that attack the trunks of planted *Casuarina* trees; owls were said to end the beetle invasion in short order. Moreover, and thanks to the recent efforts of conservationists, many rural people in the USA and

The populations of many owls are being reduced as a result of the disappearance of forest. This problem is particularly acute in the Philippines, where forest destruction has continued unabated for some decades. The Philippine Hawk-owl tolerates a moderate degree of habitat alteration and remains fairly common locally. The subspecies occurring on Mindoro, for instance, is common within the largest forest remnant left on that island, over 90% of which has been deforested. This race is considered by some to be a full species, and this photograph is probably one of the first taken of this form.

[*Ninox philippensis mindorensis*, Sablayan, Mindoro, Philippines.

Canada, as well as in Europe, have been enlightened to the fact that having an owl on one's property is beneficial.

Among the owls identifiably mentioned in the Old Testament of the Bible are the Eurasian Eagle-owl and the Tawny, Hume's, Little, Northern Long-eared and Short-eared Owls. Jewish people believed that owls were unwholesome because they ate raw meat and carrion and chose to live in derelict and desolate places. Aristotle, who lived from 384 to 322 bc, almost certainly was the first scientist who studied owls, among so many other things. For instance, the antagonistic relationship between owls and crows was mentioned in his book *Historia Animalium*.

Since the time of Aristotle, owls have been admired by scholars, artists and poets. A famous owl painting is that of Albrecht Dürer: reproductions of his 1508 painting of a Little Owl are owned by many owl-collectors and also appear on postcards and in books. Even Picasso painted an owl, an abstract figure that resembles a strigid and is dated to March 1957.

Owls have also figured prominently in English literature, as any lover of Shakespeare well knows (see page 60). For Shakespeare, the owl was clearly a bird of ill omen. In the nineteenth century, the Italian writer Giuseppe Gene wrote that the owl is very beneficial because it preys almost exclusively on vermin and is thus an ally to the farmer. In this light, Gene attacked, among other things, the barbaric custom almost everywhere in Europe of nailing an owl's carcass to the door of a house or barn, an act stemming from the erroneous belief that owls commonly killed farmyard animals or domesticated birds such as doves. He also pragmatically opposed the myth that perched and calling owls are messengers of death; according to Gene, an owl is just as likely to settle on and call from a house in which the occupants all enjoy the best of health, and it should, therefore, be seen as an omen of good fortune.

Owls were also a popular subject in the "nonsense" writings of Edward Lear in the nineteenth century. In the 1830's, Lear became one of the world's greatest bird-painters, and he had a special fascination with owls. His depiction of the Eurasian Eagle-owl in John Gould's *The Birds of Europe* (1832-1837) is today the most famous and sought-after plate among the 3000 illustrations produced in Gould's works. Sadly, Lear quit ornithological illustration in 1837, but he never forgot his beloved owls. In the limerick *Old Man of Dumbree*, Lear wrote:

There was an old man of Dumbree,
Who taught little owls to drink Tea,
For he said, "To eat mice
Is not proper or nice",
That amiable Man of Dumbree.

The Eurasian Eagle-owl may be the model for Lear's *The Owl and the Pussycat*, written in 1868 and published two years later:

The Owl and the Pussy-Cat went to sea
In a beautiful pea-green boat.
They took some honey and plenty of money
Wrapped up in a five-pound note.
The Owl looked up to the stars above,
And sang to a small guitar,
"O lovely Pussy, O Pussy my love!
What a beautiful Pussy you are –
You are;
What a beautiful Pussy you are."

Pussy said to the Owl, "You elegant fowl,
How charmingly sweet you sing!
O, let us be married – too long we have tarried –
But what shall we do for a ring?"
They sailed away for a year and a day,
To the land where the bong tree grows;
And there, in a wood, a Piggy-wig stood –
With a ring at the end of his nose,
His nose;
With a ring at the end of his nose.

"Dear Pig, are you willing to sell for one shilling
Your ring?" Said the Piggy, "I will."
So they took it away and were married next day
By the Turkey who lives on the hill.
They dined upon mince and slices of quince,
Which they ate with a runcible spoon;
And hand in hand, on the edge of the sand,
They danced by the light of the moon –
The moon;
They danced by the light of the moon.

Exploitation and "tidying" of forest means that fewer old trees and fewer holes are left for owls to nest in.

Since many owl species are reliant on tree cavities for breeding and roosting, the loss of so many sites is potentially very serious.

A particular case involves the Boreal Owl. This owl

nests mostly in old woodpecker holes,

predominantly those built by *Dryocopus* species,

and its habitat therefore has to contain trees of the

size preferred by those woodpeckers. In many

parts of its range, the removal of these trees has

created a major problem for the owl. One way in

which man has been able to help is by providing

artificial nestboxes, and such action has

proved highly successful. In Finnish forests, where

the large trees favoured by Black Woodpeckers

(*Dryocopus martius*) are now rare, about 95% of

Boreal Owls nest in boxes designed specially for them. Here, an adult

Boreal Owl is arriving at its nest inside an old

Norway spruce (*Picea abies*), carrying a wood

mouse (*Apodemus sylvaticus*); the young are

about 27 days old, and will leave the nest within a few

days. The plumage of the owlets at fledging is of

interest, being very different from that of the

adults: the juveniles are almost wholly chocolate-

brown, much as shown in this photograph, and the

young will not acquire adult-like plumage for

three months or more.

A further excellent example of the owl in literature is *Lady Grayl: Owl with a Mission*, written by R. W. Nero in 1994. This book is a kind of love story between the author and his tame Great Grey Owl. Nero took his beautiful "girlfriend" to countless schools and public meetings in Canada to "preach the gospel of conservation". Using his own words as an example: "Nowadays I find myself interacting with Grayl as if she were more than a bird, as if she could understand me. It's silly, but there is some sort of relationship between us, such that she greets when I come to her pen, a soft cooing or humming sound. I either reply in kind, or speak directly to her." Also included in Nero's book is the following poem, *The Owl's Gift*:

In the dark rainy night
I consult with this oracle
reaching through soft feathers
to feel her warm throat
thinking as I do that
the fabric of her being
is mere thin skin stretched
over braced bones and flesh
a fragile assemblage
to so command our attention.

So then where's the spirit of
this comforting creature that
ceaselessly charms us all?
It must be in her mind
(do birds have minds?)
It's in her attitude, the way
she trusts us and accepts us;
she comes from her owl-being
to meet us in her time
gravely allowing us a
glimpse of her world
a gift of tender tolerance
we do well to honour.

During the last 30 years or so, the keeping of captive owls for rehabilitation and breeding purposes has become very common in Britain, Germany, France and the USA. Many of the 500 or more captive-breeders are serious conservationists who strive to help the diminishing wild populations of rare species. Some facilities are strictly for keeping owls for rehabilitation and study, whereas others include educational programmes. Without question, well-organized demonstrations can add to the general knowledge of owl biology, without which conservation efforts would not be successful. Unfortunately, some of the owners are keen only on making money from selling owls, or they seem to obtain rather dubious satisfaction from having a collection of rare owls in captivity. The International Owl Society (IOS) is a serious effort to advise owl-keepers by grouping them together and sharing information through the society's magazine, *Tyto*. The IOS stresses the fact that in Britain it is an offence to sell, or to offer to buy or sell, most wild birds, dead or alive, without a licence or exemption from the Department of the Environment, or, in the case of dead birds only, registration under the Wildlife and Countryside Act 1981. Although these conditions apply in Britain, it is worth remembering that similar rules and acts are also in place in most countries of the world.

Status and Conservation

It should come as no surprise that information on the status and ecology of most strigid populations is woefully incomplete. This fact has important implications for conservation, because it is difficult to safeguard a species without a thorough understanding of its ecology. On balance, humans have exerted a negative influence on owls, as they have on most groups of birds, and, despite the recent upsurging interest in bird conservation, the situation is likely to get worse before it gets better. Part of the problem is that the largest numbers of strigid species inhabit areas of tropical forest, and these are being ravaged at a rapid pace.

Habitat degradation, coupled with subsistence-hunting, has led to a huge decrease in the population of the Philippine Eagle-owl. Although one was reported in 1994 from Bohol, where the species had never previously been recorded, there are very few recent records of this magnificent species, and all of those are from Luzon, where this captive individual was photographed. This eagle-owl is one of a number of Endangered species inhabiting the islands.

[*Bubo philippensis*,
Manila, Luzon,
Philippines.
Photo: Clifford &
Dawn Frith]

In addition, many species are endemic to islands and therefore have small population sizes and restricted geographical ranges, making them vulnerable to habitat alteration and other unnatural factors that could increase predation risk, destroy scarce nesting sites and reduce food availability. Further, because of the difficulty in determining species limits, especially in the tropics (see Systematics), an undetermined number of species yet to be formally recognized can almost certainly be considered in peril, unbeknown to scientists and conservationists. The sad conclusion of these factors is that several species of owl are likely to disappear before we have learned even the most rudimentary aspects of their biology.

That owls endemic to islands are highly vulnerable to extinction is reflected by the fact that each of the taxa thought to have become extinct in the last 300 years inhabited islands. Tracing the history of these extinctions is difficult, because most of the taxa disappeared before scientists had viewed them in the field. For example, the physical evidence for the occurrence of two strigids on Rodrigues Island, in the Indian Ocean, consists only of bones. The Rodrigues Little Owl (*Athene murivora*) was described from a tibiotarsus and a mandible. Its presence was also supported in an anonymous manuscript located in Paris and entitled *Relation de l'Île Rodrigue*. In that document, an owl is described as one "which is very like the brown owl, and which eats little birds and small lizards. They almost always live in trees, and when they think the weather will be fine, they utter always the same cry at night." The Rodrigues Little Owl became extinct some time around 1730. The taxonomic identity of the second species from Rodrigues, Leguat's Owl (*Bubo leguati*), is not known with certainty. Described by Lord Rothschild, Leguat's Owl is known from a single tibiotarsus bone that is too large to be assigned to *Athene murivora*; in his book *Extinct and Vanishing Birds of the World*, J. C. Greenway remarked of Leguat's Owl that "it is now impossible even to assign it to a given genus". Regardless, Leguat's Owl was a distinct species, whether it belonged to *Bubo* or to another genus. Judging from the records of explorers to Rodrigues, Leguat's Owl probably disappeared from the island during the 1690's.

Also in the Indian Ocean, two strigids have become extinct on Mauritius: the Mauritius Scops-owl (*Otus commersoni*) and the

Mauritius Owl (*Strix sauzieri*). The latter is known only from bones, and the former from written descriptions of a large owl, nearly 60 cm in total length, with prominent ear-tufts and naked tarsi. Because of its large size, "*Otus commersoni*" may well have belonged to *Asio*; it was last reported in the forest of Mauritius in 1837.

Six of the 21 named subspecies of the Burrowing Owl are endemic to islands. Two that inhabited the West Indies, the race *guadeloupensis* of Guadeloupe and the race *amaura* of Antigua, became extinct around 1890. Both disappeared following the introduction of mongooses into the islands. The presence of man, either directly or indirectly, almost certainly brought about the demise of four species of *Grallistrix* that inhabited the Hawaiian Islands more than 1000 years ago (see Systematics), and several other taxa disappeared from islands in the Pacific and the Mediterranean after the arrival of humans. Without question, the number of strigid species driven to extinction following the colonization of islands by human beings is much larger than the above examples suggest.

In New Zealand, two races of the Laughing Owl, *albigacies* and *rufifacies*, inhabited South Island and North Island, respectively. The North Island race became extinct in about 1890. The decline of both subspecies coincided with increased numbers of ferrets, weasels and cats, which had been introduced to New Zealand to control rabbits. These predators undoubtedly found the owls and their nests to be easy prey. The South Island owls have not been observed since the 1950's, and many biologists have assumed that this race, too, is extinct. It is possible, albeit unlikely, that a few Laughing Owls exist in remote portions of the South Island's Southern Alps.

According to BirdLife International's 1994 appraisal of globally threatened birds, 21 (11%) of the 189 species of strigids known to be alive today are in danger of extinction, and another 14 (7.4%) are classified as Near-threatened. All but two of the threatened species live in the tropics, and many inhabit islands. BirdLife's classification scheme places threatened species into one of three categories, based on perceived risk of extinction. Critically Endangered species are at extremely high risk, with an estimated probability of extinction of 50% within five years. Endangered species face a 20% probability of extinction within 20 years, and Vulnerable species have an estimated probability of extinction of 10% within 100 years.

Four strigid species are considered Critically Endangered: these are the Seychelles Scops-owl, the Anjouan Scops-owl (*Otus capnodes*), the Comoro Scops-owl (*Otus pauliani*) and the Forest Owlet. The three scops-owls are endemic to islands in the Indian Ocean, where all are threatened by deforestation. The Seychelles Scops-owl occurs only in upland rainforest on the island of Mahé, the largest of the Seychelles; perhaps 80 pairs remain at 250-600 m elevation in an area threatened by the continued expansion of timber-collecting.

The Anjouan Scops-owl, which originally occurred on the islands of Anjouan (Ndzuani) and perhaps also Mayotte (Maore) in the Comoro Archipelago, was rediscovered in 1992 after not having been recorded for more than 100 years. Its initial disappearance was attributed to over-collecting by H. Humblot, who is suspected of having taken at least 33 specimens between 1884 and 1886. In 1993, R. J. Safford and associates estimated that 100-200 pairs were still present on Anjouan, in patches of upland forest above 800 m; unfortunately, more recent work indicates that only about 50 birds survive in a 10-km² block of forest that constitutes the last vestige of suitable habitat on Anjouan. Habitat loss is an obvious factor in the decline of this scops-owl, but it is also captured and eaten by people. Prospects for the species' survival are bleak, and it has been suggested that birds be translocated to nearby Moheli Island, which has been much less disturbed by humans and is the site of a proposed forest reserve; however, given the presence of the newly described Moheli Scops-owl on this small island (see Systematics), plans to introduce a second species of scops-owl would have to proceed with extreme caution, if at all.

Comoro Scops-owls are confined to wet, high-elevation forest on Grand Comoro (Ngazidja), which is the largest of the Comoro Islands. In late 1989, about 1000 pairs were estimated to inhabit 100 km² of suitable habitat existing on three sides of the island's highest peak, Mount Karthala. The forested parts of Grand Comoro are highly disturbed owing to widespread burning and logging, but trees that have colonized recent lava flows on Mount Karthala may provide habitat for the Comoro Scops-owl, and part of the mountain has been proposed as a forest preserve. In addition to habitat destruction, Comoro Scops-owls are considered to be vulnerable to competition for nesting cavities with introduced Common Mynas (*Acridotheres tristis*), which are increasing their range on the island.

Much attention has been focused in recent years on the plight of the Spotted Owl. This owl's requirement for old-growth and mature forest meant that a direct conflict arose between commercial interests and the aims of wildlife conservation. Despite management plans designed to assist the species' declining populations, the value of mature forest to the timber industry was so high that great pressure was put on politicians and land-managers to permit more cutting. After much discussion, scientists, politicians and commercial interests have failed to reach an agreement over the management of this owl's habitat, so that its future remains uncertain. The Mexican race, shown here, numbers no more than 1600 individuals, and is in a particularly perilous situation.

[*Strix occidentalis lucida*,
Arizona, USA.
Photo: John Cancalosi]

The rediscovery of the Forest Owlet more than 113 years after the last verified record is one of the most exciting ornithological events of the late twentieth century. During November 1997, P. C. Rasmussen, B. King and D. F. Abbott covered a 1200-km swath across central India in search of this elusive owl. Miraculously, they succeeded in locating a Forest Owlet in dry deciduous forest in the Tapti River Valley. The site was a new location for the species, and was 200 m higher in elevation than anywhere else where the bird had been encountered previously. The team returned the next day and found a second individual, and then relocated the original bird the day after that. In June 1998, Rasmussen revisited the region with a team of biologists from the Bombay Natural History Society. Team-members located a total of five Forest Owlets in two different areas in June and July, and they also obtained recordings of vocalizations and collected data on habitat characteristics and the species' behaviour. The owls occurred in densely forested valleys dominated by teak (*Tectona grandis*) trees. In the six months that had elapsed since Rasmussen's first visit, the area of forested habitat where the owls occurred had diminished drastically because of tree-cutting for cultivation. On the one hand, the rediscovery of the Forest Owlet, and the possibility that it occurs in other areas of similar habitat, is greatly encouraging. On the other hand, however, continued deforestation within the known range of the species is likely to be having a severe negative effect on the population, underscoring the need to survey the remaining habitat and to institute protective measures, if possible, wherever the owls are found.

Two of the four strigids classified as Endangered are from the Philippines: the Giant Scops-owl and the Philippine Eagle-owl (*Bubo philippensis*). Both species inhabit severely degraded rainforest on Mindanao, mainly in the lowlands, and the eagle-owl also occurs on Luzon, where it suffers from subsistence-hunting in addition to habitat degradation. Unfortunately, the same problem that besets these species, namely severe loss of habitat,

has also affected the Luzon Scops-owl (*Otus longicornis*), Mindoro Scops-owl (*Otus mindorensis*), Mindanao Scops-owl (*Otus mirus*) and Palawan Scops-owl, each of which is classified as Vulnerable. The first three species are probably not in immediate danger of extinction, because they inhabit montane forest that is typically the last to be cleared. However, the Palawan Scops-owl occurs in lowland forest, a habitat that is disappearing rapidly on the island, but it has also been found in mixed forest associated with cultivation. There are no population estimates available for these four scops-owls, but their numbers are almost certainly declining as the forested areas they inhabit continue to be destroyed and fragmented.

Blakiston's Eagle-owl is classified as Endangered. The Japanese declared it a "National Monument" in 1971, and the Ainu people of Hokkaido, northern Japan, called it "the god who defends the village", but despite such apparent reverence Blakiston's Eagle-owl has become a text-book example of a species that has declined at the hands of man. Only 300-400 pairs were estimated to occur in the Russian Far East in the mid-1980's, and about 80-100 birds, including 20 breeding pairs, were thought to reside on Hokkaido in 1991; Blakiston's Eagle-owl also occurred in north-eastern China, but may by now have been extirpated there. In 1998, T. Takenaka estimated that 30 breeding pairs and 120 individuals inhabited Hokkaido, with most of the birds occurring in the north-eastern corner of the island. Human encroachment, destruction of riparian forest, indiscriminate shooting, and depletion of fish populations are the major threats to the species. The situation is especially serious on Hokkaido, where most of the native forest has been converted to conifer plantations. Nearly 25% of the pairs on Hokkaido rely on an artificial feeding programme, and 40% of the breeding pairs nest exclusively in boxes. Although the small increase in population size between 1991 and 1998 may reflect the success of management efforts, recently documented cases of close inbreeding have been attributed to young birds returning to artificial feeding sites in their natal home range rather than dispersing naturally. Add to this the declining fish populations caused by dam construction and commercial fishing, and one is forced to conclude that the presence of humans continues to threaten the future of this magnificent species.

The Rufous Fishing-owl, the fourth Endangered strigid, is confined to the Upper Guinea forest and coastal mangroves in Guinea, Sierra Leone, Liberia, Ivory Coast and Ghana, and it has recently been found also in Nigeria. About 80% of the Upper Guinea forest is gone, and the remaining tracts are being felled so rapidly that most of the native forest outside protected reserves is expected to disappear within 20 years. To make matters worse, civil unrest in Liberia threatens the forest within Sapo National Park, so "protected" forest areas are in some cases vulnerable to disturbance as well. Nowhere common, the Rufous Fishing-owl is known from fewer than 30 records. It appears to be widespread only in Liberia and Sierra Leone, but even in these areas waste products from iron mines have severely polluted the rivers on which these owls depend for their food.

The three scops-owls that are classified as Vulnerable face the same combination of problems as the other threatened species: tropical deforestation and restricted geographical range. White-fronted Scops-owls inhabit lowland forest in South-east Asia and adjacent Indonesia. The extensive clearing of forest in this region is a well-known and serious problem, and it has imperilled a large number of bird species. Because they are lowland specialists, it will be difficult for White-fronted Scops-owls to maintain viable populations as habitat fragmentation continues. The Javan Scops-owl (*Otus angelinae*) is known from only two areas of montane forest in Java; it is quite secretive, and its exact status is unknown. The Sokoke Scops-owl (*Otus irenae*) is another lowland-forest specialist, until recently thought to be confined to the Arabuko-Sokoke Forest on the Kenyan coast, where a 1994 survey estimated that about 925 pairs occurred over an area of roughly 250 km². Since 1992, several Sokoke Scops-owls have been found in forest on the lower slopes of the East Usambara Mountains in north-eastern Tanzania, increasing hopes that larger numbers may occur there. Most of the world's Usambara Eagle-owls (*Bubo vosseleri*), numbering between 200 and 1000 individuals, inhabit evergreen forest at 200-1500 m elevation in the East Usambaras; a few indi-

The Usambara Eagle-owl is typical of a forest species with a restricted range that is threatened by habitat destruction. This owl, until fairly recently thought to be merely a subspecies of the more widespread Fraser's Eagle-owl (Bubo poensis), is found only in the Usambara and Uluguru Mountains of north-east Tanzania. As in so many parts of the world, development of the forest is the primary cause of concern. This species, a captive individual of which is shown here, is therefore considered Vulnerable.

[*Bubo vosseleri*.

David Hosking/FLPA]

Another species with a very restricted range in East Africa is the Sokoke Scops-owl. Until recently, this species was thought to be found nowhere outside the Arabuko-Sokoke Forest of coastal Kenya, a comparatively small area of approximately 372 km² in extent and holding a population of some 1000 pairs of these owls. With proper conservation and management of the forest, it would be possible to secure the survival of this and other species occurring in the region, but a long-term programme with this objective may have been jeopardized by withdrawal of financial support.

A glimmer of hope remains, however, since this scops-owl may be present also in the Kambai Forest Reserve in the East Usambaras of north-east Tanzania. In the latter region, two forest-conservation projects currently being undertaken should therefore assist not only the Usambara Eagle-owl (*Bubo vosseleri*), but also the Sokoke Scops-owl, both listed as Vulnerable by Birdlife International.

[*Otus ireneae*,
Arabuko-Sokoke Forest,
Kenya.
Photo: Luiz Claudio Marigo]

viduals of this Vulnerable species were recently discovered in the Uluguru Mountains south of the Usambaras, and a small number may also occur in the Nguru Mountains. Clearing of forest for subsistence-farming and tea plantations continues to be a problem in the region, and efforts to conserve lowland and montane forest in East Africa have been hampered by poor funding.

Apart from Blakiston's Eagle-owl, the Sichuan Wood-owl (*Strix davidi*) is the only other threatened strigid that occurs outside the tropics. Endemic to a small area in Qinghai and Sichuan provinces in China, it occupies areas of coniferous and mixed coniferous-deciduous forest at 2700-4200 m. This owl is considered by some authorities to be a subspecies of the widespread Ural Owl, but almost nothing is known of its biology. The main threat to the species is widespread deforestation, because its range is within one of the top timber-producing regions in China.

The mountains above the Albertine Rift Valley, along the borders of Zaire, Rwanda and Uganda, support another restricted-range species, the Albertine Owlet. Known from five records in scattered localities in the region, this rare and poorly known species is threatened by deforestation in the name of agriculture, timber production and gold-mining. The Albertine Owlet inhabits both montane and transitional forest. Although the transitional forest is accessible to farmers and thus in danger of clearing, hope exists for the species because the montane forest above the transitional zone is relatively intact. Political unrest in the area inhabited by this owl makes it difficult to predict the outcome of conservation measures.

The genus *Ninox* includes two species formally listed as Vulnerable and several other taxa that may warrant this designation. The Powerful Owl inhabits the band of eucalypt forest that stretches across south-eastern Australia from southern Queensland to Victoria. Although large numbers of individuals, perhaps as many as 10,000, occur in the area, much of the lowland forest frequented by this species has been cleared for agriculture. The Powerful Owl is especially vulnerable to loss of old-growth forest, a habitat that provides a high diversity of prey species and the large trees needed for nesting. The Sumba Boobook, endemic to the island of that name in the Lesser Sundas, is a poorly known species apparently confined to lowland rainforest and monsoon-forest. Significant amounts of forest have been cleared on Sumba to make way for cattle grazing and to provide firewood, and most of the forest that remains is highly fragmented.

The Christmas Hawk-owl is a *de facto* threatened species. Formerly considered a subspecies of the Moluccan Hawk-owl,

it is confined to the tiny 140-km² Christmas Island in the Indian Ocean. Despite its restricted range, it is fairly common, with an island-wide estimate of 560 pairs in 1997. Nonetheless, numbers must surely have declined since human settlement, owing to the clearing of 25% of the native forest for phosphate-mining earlier in the century. The Moluccan Hawk-owl complex contains several taxa that may prove to be valid species, including *hypogramma* from the Northern Moluccas, *hantu* from Buru, nominate *squamipila* from Seram, and *forbesi* from the Tanimbar Islands; each of these has a restricted range in Indonesia, and a taxonomic revision of the complex would probably result in important changes in the classification of the group, with significant implications for conservation. Likewise, the Philippine Hawk-owl may in fact constitute two species, one of which is probably threatened.

Until fairly recently, Hume's Owl was considered to be quite rare. Occurring only in Pakistan, southern Israel and the Sinai and Arabian Peninsulas, the species remained virtually unknown between 1878, when the type specimen was obtained in Pakistan, and the 1920's, when additional specimens were collected in the Judean Desert. One of several results of the oil boom in the Middle East was increased ornithological exploration of the region, and by 1975 Hume's Owl was known to be relatively common in Israel. Although this species has not been recorded in Pakistan since the first specimen was collected there in Makran, this region has not been well explored by ornithologists since the 1920's, so it is possible that small numbers still survive there.

The Fearful Owl occurs in primary and secondary rainforest at up to 500 m elevation on several of the larger islands in the Solomon chain. On the basis of BirdLife International's Endemic Bird Areas (EBA) scheme, more restricted-range species occur in the Solomons than in any other EBA. Much of the forest below 400 m has been commercially logged or cleared for coconut groves, and hunting is common on the islands. Very little is known about this owl's biology and population status, but, given its affinity for lowland forest, its numbers will almost certainly have declined during the twentieth century.

The philosophy behind BirdLife's Near-threatened designation arose from a need to highlight species that are close to being classified as threatened and for which considerably more information is needed in order to permit useful assessments. Six of the 14 Near-threatened strigids inhabit islands in the Old World, and each faces threats from deforestation: these are the Andaman Scops-owl, Sao Tome Scops-owl (*Otus hartlaubi*), Pemba Scops-owl, Wallace's Scops-owl (*Otus silvicola*), Chestnut-backed Owlet and Andaman Hawk-owl (*Ninox affinis*). In the New World tropics, so little is known about the Bearded and Colombian Screech-owls, the Unspotted Saw-whet Owl and the Buff-fronted Owl that the status of each is quite uncertain. Another two species, the Forest Eagle-owl and the Tawny Fish-owl, are fairly widespread in South-east Asia and adjacent China, but the montane forest they inhabit is fragmented and constantly threatened with destruction.

High-elevation cloudforest in the northern Andes of Peru supports the only known population of the Long-whiskered Owlet. This is a Near-threatened species because even small amounts of disturbance within its restricted range would be detrimental. Sadly, a recent survey in the Cordillera de Colán, one of only two localities known for the owl, revealed an "alarmingly high" rate of deforestation, with most of the forest having been cleared for marijuana and coffee plantations.

The Spotted Owl is the best-known strigid on the list of Near-threatened species, and it must certainly be the most abundant owl in this group. Realization in the 1970's that Spotted Owls in the Pacific North-west were confined to old-growth and mature forest, which is a scarce commodity in the region, led to a tremendous amount of research and management attention. Indeed, the species soon became the most-studied strigid in North America, if not the entire world. Concern for the owls on account of widespread loss of habitat and declining population sizes led to the designation of the northern (*caurina*) and Mexican (*lucida*) races as Threatened under the US Endangered Species Act in 1990 and 1993, respectively. The political, legal and economic ramifications of these listings had a profound influence

Three of the four Critically Endangered strigids are confined to islands in the Indian Ocean, where all are threatened by deforestation.

The Seychelles Scops-owl is found only on Mahé, the largest of the Seychelles group. It occurs at 250-600 m in the upland rainforest, where a population of no more than about 80 pairs is thought to survive. Even on this island, popular with tourists and frequently visited by scientists and conservationists, the forest habitat is under continued threat from the activities of timber-collectors.

[*Otus insularis*, Mahé, Seychelles. Photo: Eric & David Hosking/FLPA]

In eastern Asia, Blakiston's Eagle-owl offers a classic example of a species that has declined because of man's activities. This handsome and imposing owl was declared a "National Monument" in Japan in 1971, and was apparently revered by local tribespeople on Hokkaido, yet by 1991 its population on the latter island had plummeted to about 100 individuals, including 20 breeding pairs. A 1998 estimate put the Hokkaido population at 30 breeding pairs and 120 individual birds, mostly inhabiting the north-east of the island. Elsewhere, up to 400 pairs breed in south-east Russia, but the species is probably extinct in adjacent north-east China. This sorry situation has been brought about by destruction of native riparian forest, combined with human disturbance, persecution by hunters, and depletion of the fish stocks on which this owl lives. On Hokkaido, most of the natural forest has been replaced by conifers, and some 40% of the breeding pairs now nest solely in artificial boxes, while 25% of them are dependent on an artificial feeding programme. Moreover, immatures, rather than dispersing more widely, seem to return to feeding stations within their natal areas, leading to inbreeding among the small population. With fish stocks continuing to decrease as a result of commercial over-fishing and dam construction, the prospects for this Endangered owl, at least on Hokkaido, do not look good.

on wildlife management in the USA, and the Spotted Owl quickly became the hallmark species for conservation of old-growth forest in western North America.

The problem was, of course, that the commercial value of the mature forest required by the owls was extremely high, and the timber industry placed enormous pressure on land-managers and politicians to allow more cutting. By 1994, loss of old-growth habitat in the physiographic provinces of the Pacific North-west ranged from 54% to 99%. To make matters worse, unknown persons in some timber-dependent communities began shooting the owls, although mortality from this practice was thought to be low. In addition, recent range expansion by the closely related and more aggressive Barred Owl resulted in several cases of hybridization with Spotted Owls and may also have caused territory abandonment and direct mortality. Minimum estimates of population size, based on summaries by J. R. Gutiérrez and associates in 1995, gave about 3780 pairs and 1000 territorial individuals for the northern race, 3050 individuals for the Californian race *occidentalis*, and 800-1600 individuals for the Mexican race.

Three major conservation plans for Northern Spotted Owls were generated under the sponsorship of the US Government. The 1988 plan called for a series of 400-ha management areas in widely scattered localities in the Pacific North-west. The plan was soon abandoned, however, because it was deemed to have an unacceptably low probability of success. The second plan, put forth in 1990, recommended that large blocks of habitat on government-managed lands be set aside at intervals of 10-20 km. This plan was halted by litigation that forced the government to widen their conservation efforts to include all species associated with older forest in the region. A recovery plan as dictated by the Endangered Species Act was drafted in 1992, some 20 years after the owl was first known to be in trouble. This last effort was patterned after the 1990 plan, and included de-listing criteria and a formal recovery strategy. Largely for political reasons, however, the US Department of the Interior did not accept the plan, and no official recovery programme therefore exists for the species! Each of these plans has been criticized by scientists for being inadequate for the protection of viable populations of owls, while at the same time being distasteful to the timber industry,

which is already facing economic hardships independent of the Spotted Owl problem. As a result, scientists, politicians and commercial interests continue to disagree over the management of old-growth forest in general and Northern Spotted Owls in particular, and the situation is likely to remain unresolved for the near future.

Despite the plethora of negative factors stacked against it, the Spotted Owl's plight is not hopeless. The species will use intermediate-aged stands provided that key habitat elements, namely snags and large trees for nesting and cool micro-sites for roosting, are present, although the long-term reproductive success in these "second-class" habitats is unknown. Based on an increasingly large sample of marked individuals, research into demographics and other life-history aspects of the Spotted Owl will continue. Indeed, the population data gathered so far are among the best ever assembled for any owl, and, as knowledge of the species accumulates, the potential for solving some of its problems will increase as well.

As should be abundantly clear at this point, habitat loss is the greatest problem faced by strigids. The wide-scale degradation of forest habitat influences owls in several ways. First, many species rely on pre-existing tree cavities for nesting, and suitable sites are often limited even under natural conditions; thus, any reduction in the availability of cavity-bearing trees could have drastic effects on productivity. The problem can be especially acute for the larger species such as the Forest and Blakiston's Eagle-owls, Buffy Fish-owl, Pel's Fishing-owl, Spotted Owl and Powerful Owl, because the large trees they need for nesting are typically the first to go when a forest is exploited for saw timber. Second, severe fragmentation of forest interferes with the natural dispersal tendencies of owls and their prey species and reduces the amount of suitable habitat such that densities exceed carrying capacities; in this manner, fragmentation disrupts the functioning of entire communities, and organisms such as owls that are at the top of the food chain are often the most susceptible to the negative influences of these changes. Finally, some strigids simply cannot tolerate disturbance, in which case human encroachment can render an area unsuitable, even with relatively benign levels of habitat alteration.

By virtue of their predatory habits, raptors experience a suite of man-induced problems that seldom affect other groups of birds. For example, many owls are killed while pursuing prey, either being struck by automobiles or colliding with fences and

One of the least well-known of the world's strigids is the Javan Scops-owl. Indeed, this is believed to be the first colour photograph ever taken of this very rare species, which is listed as Vulnerable. It is known from only a couple of localities in western Java, where it inhabits montane forest. This owl appears to be unusually silent, making the task of monitoring it even more difficult. Its exact status is therefore uncertain, but the fact that forest areas throughout the world are fragile and threatened habitats is sufficient cause for concern over its conservation.

Although large numbers of Powerful Owls are estimated to live within the species' range in south-eastern Australia, this owl faces the same familiar problems as beset so many other strigids. Possibly as many as 10,000 individuals are thought to live in the eucalypt forest stretching from southern Queensland to Victoria, but here, as elsewhere, much of the lowland forest has already been cleared for agriculture. Loss of the nest-sites provided by old-growth forest, along with intensive forestry practices that reduce prey numbers, have made this once common species Vulnerable.

Found nowhere but on the volcano of Mount Karthala, the Comoro Scops-owl is considered Critically Endangered. It inhabits the highest forest areas, where available suitable habitat has been estimated at about 100 km². Although 1000 or more pairs could live within this area, the forest is suffering fragmentation through logging and fires. In addition, this owl has to face competition for nest-sites from the introduced Common Myna (*Acridotheres tristis*), which is spreading on the island. The Comoro Scops-owl is known only from the type specimen and a few photographs, the best of which is published here.

powerlines. Larger owls such as *Bubo* and *Strix* are often electrocuted when they perch next to transformers and close-set powerlines. Collisions with and electrocutions by powerlines are thought to be especially important causes of mortality for Eurasian Eagle-owls in Sweden and Germany.

The killing of raptors in the belief that they are harming gamebird populations or preying on livestock continues to be a problem for hawks and eagles in some parts of North America, but the problem is probably not so great for owls. The situation appears to be different in Europe, however. Eurasian Eagle-owls were widely persecuted by gamekeepers and hunters during the first half of the twentieth century, and in some countries, particularly Italy, thousands of owls of several species were killed each year up to the mid-1970's. Tawny Owls are still shot or trapped near gamebird breeding pens in Britain. In eastern Russia, Blakiston's Eagle-owls are shot by hunters and fishermen during winter, when the owls are drawn to openings in the ice through which they catch fish. In many parts of China, owls are killed for medicinal purposes, despite having complete legal protection in the country, and unknown numbers of owls are shot in many developing countries, sometimes for food, sometimes out of sheer curiosity, and sometimes in the belief that they are bad omens or evil (see Relationship with Man). Owls are legally protected in most developed countries, however, and they do not seem to be the focus of systematic persecution anywhere, even in places where they continue to be shot or trapped. Moreover, it is important to keep in mind that direct mortality from the conscious acts of humans does not come close to matching the mortality that results from habitat destruction.

Pesticides pose another major threat. Use of the organochlorine DDT, in particular, had severe negative effects on breeding populations of Ospreys, Bald Eagles (*Haliaeetus leucocephalus*) and Peregrine Falcons (*Falco peregrinus*), primarily because the fish and birds on which these raptors fed had high levels of DDT residue in their tissues. Experimental studies of captive individuals suggested that owls were just as sensitive as diurnal raptors to the effects of DDT. Wild strigids largely escaped the problem, however, because the mammals and invertebrates that they consumed contained lower levels of toxins than did birds and fish.

Other pesticides have posed problems for owls on a local scale. Exposure to the anticholinesterase insecticide carbofuran

was associated with decreased reproductive success in Burrowing Owls in Canada. At various locations in the USA, carbofuran and another anticholinesterase, fenthion, caused direct mortality of Great Horned and Short-eared Owls, and mortality of Eastern Screech-owls and Great Horned Owls was attributed to organochlorines such as chlordane, dieldrin and endrin. The anticoagulant brodifacoum is used to control rodents, and a study in Virginia, USA, revealed the deaths of six Eastern Screech-owls and a Northern Long-eared Owl in fields where brodifacoum baits had been applied. In Minnesota, a Great Horned Owl and two Snowy Owls were killed after strychnine-treated grain was set out to kill Rock Doves; dove parts retrieved from the owl carcasses contained strychnine residues. The available evidence suggests that pesticides are currently not having major effects on strigid populations in North America, but the relative scarcity of studies makes it difficult to assess the extent of the problem.

The situation is much the same in Europe. Rodenticides, especially, have been linked with mortality in Barn Owls and also several strigids in Britain, and organic mercury compounds used as seed dressings caused considerable mortality of Eurasian Eagle-owls in Sweden prior to 1966. Declines in the numbers of Little Owls during the 1950's and 1960's in England and Belgium were attributed to pesticides, and, more recently, some individuals have shown evidence of PCB contamination. At present, however, evidence for widespread pesticide problems among owls seems to be absent in Europe.

Elsewhere in the world, the widespread use of insecticides has been cited as a potential problem for owls in China, but no data are available on actual contamination or mortality. Eurasian Scops-owls reportedly declined in northern Israel during the 1950's as a result of pesticide use, but the population appears now to be stable. Rodenticides have been implicated in population declines of Rufous and Barking Owls in Australia, and of Brown Fish-owls in Israel. In Kenya, a moribund Pearl-spotted Owlet was recovered one day after fenthion was applied to control a large communal roost of Red-billed Queleas (*Quelea quelea*); subsequent analysis for brain cholinesterase activity confirmed that fenthion was the cause of death.

Outside the tropics, populations of non-threatened strigids appear to be relatively stable in the New World, with the possi-

ble exception of the Burrowing Owl in North America. In response to widespread concern for the species, the First International Burrowing Owl Symposium was held in Seattle, Washington, in November 1992. The meeting attracted 130 participants from four countries, and papers were presented on a variety of topics that included population ecology and management. P. C. James and R. H. M. Espie reported the results of a survey in which they asked each wildlife agency in the 24 states and provinces within the species' range in the USA and Canada to estimate its population size and status. One state, Texas, reported a population estimate of more than 10,000 pairs, eleven states and provinces estimated 1000 to 10,000 pairs, and eight reported 100 to 1000 pairs; British Columbia, Manitoba, Minnesota and Iowa, however, reported fewer than 100 pairs. Despite these generally high numbers, 13 of the states and provinces believed that their populations were declining, and none reported an upward trend in numbers. Of the seven potential limiting factors identified, habitat loss was thought to be a major problem by 83% of respondents, rodent control and subsequent loss of nesting burrows by 54%, and pesticides by 46%. The first two factors are very likely to be real, because native grassland is fast disappearing from western North America, and the eradication of fossorial rodents, especially prairie-dogs, has been rampant. The survey revealed that hard data on Burrowing Owl population trends were scarce, despite the fact that the species is one of the world's easiest owls to observe and census. Quite appropriately, then, symposium participants identified the need to monitor population trends by means of long-term surveys as the top research priority for the species.

Interest in owl conservation is growing worldwide. The first international owl symposium, "Biology and Conservation of Northern Forest Owls", was held in Winnipeg, Manitoba, in 1987. The meeting was a huge success and was followed, ten years later nearly to the day, by the second international symposium in Winnipeg, "Biology and Conservation of Owls of the Northern Hemisphere". The inclusion of non-forest owls in this symposium reflected the increased awareness of the potential problems of all Northern Hemisphere species. The third international owl symposium will be held in Canberra, Australia, in 2000, and will be unlimited as to species and geographical coverage. Also active on a global scale is the World Working Group on Birds of Prey and Owls, which began with a focus on diurnal raptors nearly 30 years ago and has held five world conferences since its inception. The group's third conference, held in Eilat, Israel,

was noteworthy in being the first one at which the group devoted a major session to owls.

Despite the growing interest in owls, conservation efforts on their behalf have lagged behind those for falconiforms, in part because of the relative lack of pesticide problems, but also because there was no active support group for the Strigidae such as that which existed for hawks, eagles and falcons, namely falconers. The husbandry that developed through the ancient art of falconry led to practices, such as captive propagation and reintroduction, that proved to be useful techniques in the modern world. Many strigid species are held in zoos, but breeding programmes devoted to releasing owls into the wild are relatively scarce compared with those for falconiforms. Captive breeding has been successful in re-establishing Eurasian Eagle-owls in Germany and Sweden, where their populations were severely diminished in the first half of the twentieth century. Similarly, Eurasian Pygmy-owls, extirpated from Germany's Black Forest after World War II, are now flourishing in that region owing to the release of 35 captive-bred individuals between 1968 and 1971; the population currently stands at more than 150 breeding pairs. Reintroduction of captive-bred Ural Owls into the Bavarian National Park in Germany has not been quite so successful as the eagle-owl and pygmy-owl work, but five released birds became established in the wild between 1972 and 1986. The Peregrine Fund's World Center for Birds of Prey in Boise, Idaho, is one of the world leaders in captive propagation of threatened raptors. Although the Peregrine Fund has not yet bred owls in captivity, it has provided direct support for research on Mottled and Black-and-white Owls in Guatemala (the Maya Project) and on Sokoke Scops-owls in Kenya.

The most active captive-release programme in North America is for Burrowing Owls, where reintroductions have been attempted in Manitoba, British Columbia and Minnesota and have been proposed for other areas. In addition, active nests of this species that were threatened by development have been successfully moved to artificial burrows, and the owls can also be induced to settle in areas where artificial burrows have been provided in the absence of natural sites. Such willingness to accept artificial nesting structures holds much promise for the conservation of the Burrowing Owl as numbers of fossorial rodents continue to decline in western North America.

An alternative to captive-breeding was used to bolster numbers of a Critically Endangered subspecies of *Ninox* on a Pacific island. Two male Moreporks (*Ninox novaeseelandiae*) of the nomi-

A comparatively large percentage of the world's owls are poorly known, a fact which, in itself, renders their conservation status uncertain.

The Tawny-browed Owl of eastern South America is just one example.

This species inhabits tropical rainforest and open woodland, where it is considered at best uncommon. Little is known about its biology and ecology. It appears to have declined in parts of its range, with timber-cutting a probable cause, and the scale of habitat loss in other parts is thought such that monitoring of its populations is strongly advised.

Another of the world's rare and poorly known strigids is the Fearful Owl of Bougainville and two of the islands in the Solomons. This owl lives in lowland primary forest and tall secondary forest and is reported to feed on phalangers (Phalanger), which occur in large numbers on Santa Isabel and are eaten also by local people. Forest destruction, however, seems to be the main threat facing this owl, which is listed as Vulnerable.

One of the encouraging stories of the last decade of the twentieth century has been the rediscovery of the Forest Owlet. First found in 1872, the species was recorded a few times in the 1880's, but there were no further confirmed records until November 1997, when two individuals were located in dry deciduous forest in the Nandurbar district of Maharashtra, India. In June 1998, a team of scientists set out to determine the species' exact status, with detailed surveys, vegetation sampling, searching for pellets, and behavioural observations on the two individuals already found. Tape recordings of these were also made. The results should enable this rare owl's current status to be properly assessed.

nate race were released on Norfolk Island in 1987 in an attempt to provide a mate for a lone female of the race *undulata*, the Norfolk Boobook, which was believed to be the sole survivor of that race of the Morepork. Nestboxes were set out and protected from rats, and the owls were carefully monitored so as to avoid disturbance. The resident female paired with one of the males almost immediately; their first nesting attempt, in 1988, failed, but the pair succeeded in raising two chicks in each of the years 1989 and 1990. In establishing what essentially will become a population of hybrids, conservationists hope to preserve gene complexes that are adapted to life on this tiny Pacific outpost.

Artificial nests, usually in the form of nestboxes or walled platforms, have been used with great success for many species, including the Flammulated Owl, several screech-owls, Blakiston's Eagle-owl, Tawny, Ural and Great Grey Owls, Northern Hawk-owl, several pygmy-owls, and Little and Boreal Owls (see Breeding). In Britain, Northern Long-eared Owls readily take to wooden baskets placed in trees. Nestboxes are great tools that allow researchers access to owls, which can then be marked and recaptured. They also have high potential for management in areas where natural cavity nests are scarce owing to timber harvest. It is, however, important to keep in mind that management efforts should not rely on nestboxes as an alternative to implementing sound forestry practices that allow for the retention of natural nest-sites.

Although a rather dismal picture appears to have been painted for the status of many strigids, all is not gloom and doom. Many owls co-exist quite well with humans. This is illustrated by the Eurasian Scops-owl, Tawny Owl and Little Owl in Europe; the Oriental and Pallid Scops-owls and Brown Hawk-owl in Asia; the Northern White-faced Owl, Spotted Eagle-owl and Pearl-spotted Owlet in Africa; the Southern Boobook in Australia; the Morepork in New Zealand; the Ferruginous Pygmy-owl in Central and South America; and the Eastern Screech-owl, Great Horned Owl and Burrowing Owl in North America. Indeed, habitat alterations have benefited some species, especially those that hunt in more open areas. Examples include Burrowing Owls that have moved into cleared areas in South America, Northern Long-eared and Short-eared Owls that hunt in pastures that support large numbers of voles, and Snowy Owls that move south in

winter to settle in cultivated areas and open spaces adjacent to airport runways.

As is true for the conservation of any group of organisms, the future wellbeing of the Strigidae will depend in part on the success of biologists and conservationists in convincing others of the value of biodiversity, and in finding creative ways to provide people with the incentive to conserve their natural resources.

form "stresemanni"

Subfamily STRIGINAE

Tribe OTINI

Genus *OTUS* Pennant, 1769

1. White-fronted Scops-owl

Otus sagittatus

French: Petit-duc à front blanc **German:** Weißstirneule **Spanish:** Autillo Frentiblanco
Other common names: Greater/Large/Malayan Scops-owl

Taxonomy. *Ephialtes sagittatus* Cassin, 1848, Malacca.
Relationships unclear. Monotypic.

Distribution. S Myanmar (Tenasserim), S Thailand and Malay Peninsula; possibly Sumatra (status uncertain).

Descriptive notes. 25-28 cm; c. 120 g. Along with *O. megalotis*, the largest Old World *Otus*. Forehead, eyebrows, lower part of long ear-tufts and lower part of face prominently whitish; upperparts intense chestnut or rufous-brown with obscure buff spots, scapulars edged paler; tail and wings barred; underparts light cinnamon-rufous, with chestnut across upper breast, and with black arrow-shaped markings; eyes brown (sometimes yellow?); bill and feet bluish-white; tarsus feathered. Distinguished from other *Otus* by large size, longer tail and pale face markings. Sexes apparently alike. Juvenile undescribed. Voice. A hollow, whistled

"hooo" very like that of *O. rufescens*, but with more abrupt start and finish; low soft moans also described.

Habitat. Primary tropical forest, especially lowland evergreen forest in Thailand and Malaysia; also tall secondary forest and rather degraded swampy forest. Mainly a lowland specialist, but recorded in foothills to c. 700 m.

Food and Feeding. No information.

Breeding. Lays Feb-Mar; nest in tree hole; 3-4 eggs. No other information.

Movements. Resident in Thailand and, presumably, elsewhere.

Status and Conservation. VULNERABLE. CITES II. Described as rare or very rare and declining throughout its range, but very poorly known; may prove locally more common in Malaysia, e.g. at Pasoh Forest Reserve shown by long-term mist-netting to be no less common than other scops-owls, but surprisingly few recent records. In Thailand, recent reported sightings in W Central Plains, well N of previous known range, included 3 roosting together, perhaps indicative of wider distribution than realized. Only 1 record from Sumatra, of undated specimen in Aceh; perhaps only vagrant there. Although has been considered an extreme lowland-forest specialist, has been recorded in foothills and is able to tolerate rather degraded forest with swampy patches. Extensive lowland deforestation considered greatest threat to survival.

Bibliography. Andrew (1992), Collar & Andrew (1988), Collar *et al.* (1994), Delacour (1947), Glenister (1951), Holmes (1996), Lekagul & Round (1991), MacKinnon & Philipps (1993), van Marle & Voous (1988), Marshall (1978), Medway & Wells (1976), Riley (1938), Robson (1998), Round (1988), Smythies (1986), Wells (1999), Zhao Zhengjie (1995).

2. Reddish Scops-owl

Otus rufescens

French: Petit-duc roussâtre **German:** Rötteleule **Spanish:** Autillo Rojizo
Other common names: Rufescent/Rufous Scops-owl

Taxonomy. *Strix rufescens* Horsfield, 1821, Java.

Relationships unclear. Additional race *burbridgei* based on single dark-faced specimen from Sulu Is, in Philippines, but record apparently not accepted as origin of specimen disputed; description also thought possibly not outside normal variation of nominate race. Two subspecies recognized.

Subspecies and Distribution.

O. r. malayensis Hachisuka, 1934 - S peninsular Thailand and peninsular Malaysia.

O. r. rufescens (Horsfield, 1821) - Sumatra, Bangka, Java and Borneo.

Descriptive notes. 15-18 cm; c. 77 g. Forehead, conspicuous ear-tufts, eyebrows and chin pale buffy to white; upperparts tawny-rufous with small light to buff spots, particularly on scapulars, where often triangular or arrowhead-shaped; underparts paler, more cinnamon, with dark spots; iris brown or yellowish-gold; bill generally flesh-coloured to horn; feet flesh-coloured or yellowish. Differs from *O. sagittatus* in much smaller size. Juvenile similar, but less spotted. Race *malayensis* slightly more rufous above and more rufous-ochre below than nominate. Voice. A hollow whistle, "hoooo", repeated at intervals of c. 7-11 seconds.

Habitat. Lowland to submontane forest in Borneo; lowland rainforest or peat-swamp forest in Thailand and Malaysia; in Sumatra, occurs also in tall secondary forest, apparently including logged areas. Primarily a specialist of primary rainforest below c. 1000 m, mainly up to 600 m.

Food and Feeding. No information.

Breeding. Lays Mar-Apr; nestling found in Jul in Java. Nest in natural tree hole or old hole of woodpecker or barbet. Chick with reddish-brown down.

Movements. Resident; possibly some altitudinal movement locally.

Status and Conservation. Not globally threatened. CITES II. Rare throughout range, and probably declining in most parts, but elusive and little known. In S Malay Peninsula said to be regular and uncommon to more or less common, but in S peninsular Thailand known only from recently discovered population in Chalerm Prakit Wildlife Sanctuary and from Nakhon Si Thammarat. Considered threatened by habitat destruction in Thailand. Occurs in a series of protected areas throughout its range, such as Taman Negara National Park and Panti Forest Reserve in Peninsular Malaysia, Way Kambas National Park in Sumatra, and Danum Valley Conservation Area and Gunung Mulu National Park in Borneo.

Bibliography. Andrew (1992), Delacour (1947), Delacour & Mayr (1946), Glenister (1951), Holmes (1996), Holmes & Burton (1987), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), van Marle & Voous (1988), Marshall (1978), Medway & Wells (1976), Nash, S.V. & Nash (1985, 1988), Round (1988), Smythies (1981), Wells (1999).

3. Sandy Scops-owl

Otus icterorhynchus

French: Petit-duc à bec jaune **German:** Gelbschnabeule **Spanish:** Autillo Piquigualdo
Other common names: Cinnamon Scops-owl

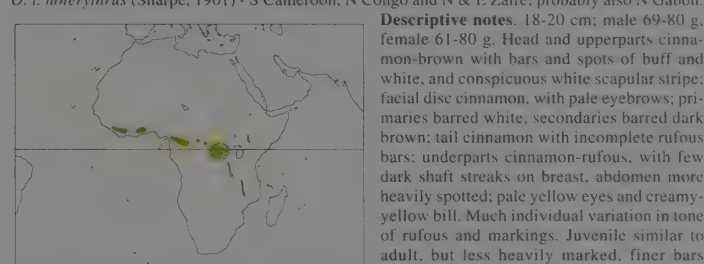

Taxonomy. *Scops icterorhynchus* Shelley, 1873, Fantee, Ghana.

Probably forms superspecies with *O. irenae*. Has been considered conspecific with Asian *O. balli* on basis of morphology, but differs significantly in plumage and vocal characters. Some authors have included Sumatran form "*stresemanni*" of *O. spilocephalus* as race of present species, or with the two forming a superspecies. Two subspecies recognized.

Subspecies and Distribution.

O. i. icterorhynchus (Shelley, 1873) - Liberia, Ivory Coast and Ghana.

O. i. holerythrus (Sharpe, 1901) - S Cameroon, N Congo and N & E Zaire; probably also N Gabon.

Descriptive notes. 18-20 cm; male 69-80 g, female 61-80 g. Head and upperparts cinnamon-brown with bars and spots of buff and white, and conspicuous white scapular stripe; facial disc cinnamon, with pale eyebrows; primaries barred white, secondaries barred dark brown; tail cinnamon with incomplete rufous bars; underparts cinnamon-rufous, with few dark shaft streaks on breast, abdomen more heavily spotted; pale yellow eyes and creamy-yellow bill. Much individual variation in tone of rufous and markings. Juvenile similar to adult, but less heavily marked, finer bars above and less streaked below. Race *holerythrus* more rufous, with less breast streaking. Voice. A drawn-out whistle, "twoooo", up to 1 second long, dropping in pitch and volume, given at intervals of 3-4 seconds. May respond to call of *Bubo poensis*.

Habitat. Lowland evergreen forest; in Liberia, recorded in high forest, including logged areas, and also in forest-shrub-grassland mosaic; in N Congo, recently reported from open-canopy forest. From sea-level to 1000 m.

Food and Feeding. Stomach contents of collected specimens included crickets and grasshoppers. Captive bird consumed only insects, taken at dawn and dusk but not during night.

Breeding. Detailed information unknown. Possibly lays Feb-Mar; nestling found in Zaire in May and juveniles in Cameroon in Apr; in Liberia (Mt Nimba), 2 males in Jun/Jul had small gonads, and female in Sept had enlarging ovaries.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Appears to be rare throughout its fragmented range; only 4 known specimens, 2 from each of Ghana and Cameroon. Assessment of status difficult, owing to its poorly documented distribution and biology. In Liberia, found to be present in all forest areas where intensive study has taken place, and thought to be probably not uncommon.

Bibliography. Bannerman (1953), Bowden & Andrews (1994), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (1999), Dowsett-Lemaire & Dowsett (1998a), Fry *et al.* (1988), Gatter (1988, 1997), Grimes (1987), Kemp & Kemp (1998), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1970), Marshall (1978), Snow (1978), Stephenson & Newby (1997), Thiollay (1985).

4. Sokoke Scops-owl

Otus irenae

French: Petit-duc d'Irène **German:** Sokokeeule **Spanish:** Autillo de Sokoke
Other common names: Morden's Scops-owl

Taxonomy. *Otus irenae* Ripley, 1966, Sokoke-Arabuku Forest, Kenya.

Probably forms superspecies with *O. icterorhynchus*. Monotypic.

Distribution. Sokoke-Arabuku Forest in SE Kenya, and NE Tanzania (lowlands N of E Usambara Mts).

Descriptive notes. c. 15-18 cm; 45-50 g. Occurs in dark brown, grey-brown and rufous morphs. Crown streaked dusky brown, small ear-tufts generally not visible in the field; nape feathers have pale bases, giving spotted effect; facial disc light rufous to brown and buff, with whitish or buffy eyebrows; wing-coverts finely vermiculated; flight-feathers barred whitish-cream and brown; tail with incomplete dark brown and pale bars; underparts paler than upperparts, with darker wash on chest, and few sooty spots; cere and eyes yellow; bill horn-coloured to blackish. Juvenile very like adult. Voice. A whistled "too-too-too..." given in series of 5-10 notes, and repeated c. 10 times per minute; calls most frequently 2 hours before dawn and 2 hours after dusk.

Habitat. Forest. Generally prefers *Cynometra-Brachylaena* forest on red magarini sands, but also occurs in *Cynometra* thicket, and in *Azelia-Cynometra* forest on white soils; occasionally wanders

into *Brachystegia* woodland; absent where canopy below 3-4 m. Lowlands up to 70 m, but found at 200-400 m in E Usambaras.

Food and Feeding. Mainly insects; stomach contents from a few individuals showed arboreal leaf-eating insects such as crickets, katydids and phasmids. Some crepuscular activity, but mostly nocturnal. May use perch for hunting, dropping on to prey; in most observations, seen perched 3-4 m above ground.

Breeding. Breeding habits unknown.

Movements. Unknown, but probably largely sedentary owing to its restricted range. Evidence of some dispersal away from normal habitat.

Status and Conservation. VULNERABLE. CITES I. Restricted-range species; present in Tanzania-Malawi Mountains EBA and East African Coastal Forests EBA. Kenyan population estimated at c. 1000 pairs in 1984, and about the same in 1994, with density of 7-8 pairs/km² in preferred habitat; considered locally common. Further study on distribution needed; may occur N of Sokoike in the Mundane Range, where suitable habitat exists; thought possibly more widespread and more numerous in N Tanzania, following records in Kambai and Kwangumi Forest Reserves. Forest destruction the major threat. Although Sokoike Forest Reserve (400 km²) provides limited forest protection, commercial logging of *Brachylaena* trees for the carving industry and other valuable timber occurs; 43 km² nature reserve established inside the forest reserve by the Kenyan Ministry of Natural Resources and, although no cutting permitted, instances of large-scale felling still reported; conservation regulations ignored perhaps because of lack of funds for enforcement. Also, areas of forest outside the reserve being cleared for exotic plantations. Proposed conservation measures include increasing size of nature reserve to 60 km², and setting aside 200 km² of surrounding forest reserve for traditional uses only; also, improving facilities for forest officers to enable them to carry out and enforce policies. Conservation efforts impeded by lack of funding.

Bibliography. Alexander (1995), Bennun & Njoroge (1996), Britton (1976, 1980), Britton & Zimmerman (1979), Britton *et al.* (1984), Brown (1977), Clark & Mikkola (1989), Collar & Andrew (1988), Collar & Stuart (1985, 1988b), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans, T.D. (1997), Evans, T.D., Hague *et al.* (1994), Evans, T.D., Tye *et al.* (1997), Evans, T.D., Watson *et al.* (1994), Fanshawe (1993, 1994), Fry *et al.* (1988), Hipkiss *et al.* (1994), Kelsey & Langton (1984), Kemp & Kemp (1998), King (1978/79), Knox & Walters (1994), Lewis & Pomeroy (1989), Marshall (1978), Ripley (1966), Ripley & Bond (1971), Short *et al.* (1990), Shuker (1993), Snow (1978), Stattersfield *et al.* (1998), Zimmerman, D.A. *et al.* (1996).

5. Andaman Scops-owl

Otus balli

French: Petit-duc des Andaman German: Andamaneule Spanish: Autillo de Andamán

Taxonomy. *Ephialtes Balli* Hume, 1873, South Andaman Island.

Probably forms superspecies with *O. alfredi* and *O. spilocephalus*. Has been considered conspecific with African *O. ieterorhynchus* on basis of morphology, but significant differences in plumage and vocal characters indicate that the two are better treated as separate species. Some authors have included Sumatran form "*stresemanni*" of *O. spilocephalus* as race of present species, or with the two forming a superspecies. Monotypic.

Distribution. Andaman Is.

Descriptive notes. 18-19 cm. Occurs in rufous and grey-brown morphs, former less variegated. Fairly prominent ear-tufts and pale eyebrows; upperparts sparsely peppered with black and whitish spots, numerous white spots on crown and neck can to some extent resemble a collar; flight-feathers barred white, brown and tan, tail barred brown and tan; underparts much paler and greyer than upperparts, chest finely vermiculated, with thin black spots throughout; iris yellow, hazel or brown; bill yellow or greenish-horn; tarsus bare for third to half its length; feet flesh-grey to greenish-yellow. Differs from *O. spilocephalus* in

rougher plumage texture, relatively more conspicuous black and white flecking over plumage and lack of pale scapular stripe. Juvenile not described. Voice. A strong, loud "hoot! hoot-curroo", with characteristically rolled "r".

Habitat. Trees in semi-open areas, settlements and cultivated areas; gardens; has been known to enter bungalows.

Food and Feeding. Primarily caterpillars, also beetles and other insects. Captures caterpillars from foliage by sidling up to them in a parrot-like fashion. Strictly nocturnal.

Breeding. Lays Feb-Apr. Nest in natural tree hollow or in abandoned hole of woodpecker or barbet, usually 2-4 m above ground, 2-3 eggs.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Andaman Islands EBA. Currently considered Near-threatened. Considered quite common, or at least readily located. Appears to accept presence of human beings, and associated with agriculture; despite this, forested habitat in Andamans is decreasing rapidly, and this could represent a threat in the long term.

Bibliography. Ali & Ripley (1981), Butler (1899), Grimmett *et al.* (1998), Inskipp *et al.* (1996), Marshall (1978), Ripley (1982), Stattersfield *et al.* (1998), Tikader (1984).

6. Flores Scops-owl

Otus alfredi

French: Petit-duc de Florès German: Floreseule Spanish: Autillo de Flores
Other common names: Everett's Owl/Scops-owl, Flores Spotted Scops-owl

Taxonomy. *Pisorhina alfredi* Hartert, 1897, Repok Mountains, above 3500 feet [c. 1100 m], Flores. Probably forms superspecies with *O. balli* and *O. spilocephalus*. Recently treated as a rufous morph of race *albiventris* of *O. magicus*, but morphological study clearly demonstrates its distinctness and validity as a species. Monotypic.

Distribution. Flores I, in Lesser Sundas.

Descriptive notes. 19 cm. Facial disc solid dark rufous-brown, with white eyebrows and rufous ear-tufts; forehead with fine white markings, crown unstreaked rufous; upperparts uniform dark rufous with no barring or streaking, but instead a hindneck-collar of small white triangles; outer webs of scapulars white with large brown spangles; flight-feathers barred rufous and white; tail essentially unbarred; underside white, chest occasionally tinted rusty-brown, with faint, fine dark vermiculation and rufous barring; bill and iris yellow; feet and claws yellow, the latter without dark tips; feet proportionately smaller than

in other *Otus*, and tarsi thickly feathered except for the bare distal quarter. Juvenile almost uniformly pale rufous with a little faint barring; tail bands more evident. VOICE. No information; believed possibly largely silent.

Habitat. Mountain forest above 1000 m.

Food and Feeding. No information.

Breeding. No information.

Movements. No information. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Northern Nusa Tenggara EBA. The little information known about this species is from original notes on the first 3 specimens, collected late in 19th century; no new specimens until one collected in May 1995 on Poco Mandasawu, and another netted and photographed in Mar 1995 in Danau Rana Mese, a crater lake within Ruteng Recreation Park, but not correctly identified until 1998. Single brief sighting in 1997, in forest near Danau Rana Mese. True status unknown, but almost certainly rare; probably not listed as threatened because true specific status misunderstood. That species occurs in a recreation park provides optimism for establishment of a protected area there.

Bibliography. Andrew (1992), Coates & Bishop (1997), Collar & Andrew (1988), Inskipp *et al.* (1996), Jepson & Monk (1995), Marshall (1978), Monk *et al.* (1997), Pilgrim & Leadley (1995), Rasmussen (1998b), Stattersfield *et al.* (1998), Sujatnika *et al.* (1995), White & Bruce (1986).

7. Mountain Scops-owl

Otus spilocephalus

French: Petit-duc tacheté German: Fuchseule Spanish: Autillo Montano
Other common names: Spotted/Spotted Mountain Scops-owl; Bornean Scops-owl (*luciae*); Vandewateri's Scops-owl (*vandewateri*); Stresemann's (Mountain) Scops-owl ("*stresemanni*")

Taxonomy. *Ephialtes spilocephalus* Blyth, 1846, Darjeeling.

Probably forms superspecies with *O. balli* and *O. alfredi*. Previously considered by some to include *O. angelinae* and *O. longicornis* as races, but differences in vocalizations indicate that all are separate species. Race *vandewateri* sometimes treated as full species, and sometimes as race of *O. angelinae*, but morphology and voice suggest better regarded as race of present species. Mt Kerinci (Sumatra) foothills form "*stresemanni*" variously regarded as race of present species, of *O. ieterorhynchus* or of *O. balli*, or even as full species forming superspecies with either of last 2; known only from single specimen collected in 1914, but has not been relocated and its status is uncertain; although has been suggested as pale form of *vandewateri*, this not borne out by comparison of the few available museum specimens. Current racial divisions and geographical limits obscure; populations in Bangladesh, Nagaland and Manipur sometimes separated as race *rupchandi*. Eight subspecies recognized.

Subspecies and Distribution.

O. s. huttoni (Hume, 1870) - N Pakistan E to C Nepal.

O. s. spilocephalus (Blyth, 1846) - C Nepal E to Arunachal Pradesh and Myanmar.

O. s. latouchi (Rickett, 1900) - N Thailand and Laos to SE China and Hainan.

O. s. hambroeki (Swinhoe, 1870) - Taiwan.

O. s. siamensis Robinson & Kloss, 1922 - S Thailand to S Vietnam.

O. s. vulpes (Ogilvie-Grant, 1906) - Malay Peninsula.

O. s. vandewateri (Robinson & Kloss, 1916) - Sumatra.

O. s. luciae (Sharpe, 1888) - Borneo.

Descriptive notes. 17-21cm; c. 55-120 g. Plumage highly variable; some races polymorphic. Nominate race with facial disc whitish to light rufous with light brown bars, whitish eyebrows; upperparts rufous-brown, varying from russet to dusky brown, vermiculated darker, with crown and relatively small ear-tufts black-spotted; sometimes hint of pale hindneck-collar; scapulars with black tipped silver-white spots; flight-feathers and tail barred; underparts finely vermiculated rufous and buff, with paired small black and white spots; tarsus completely feathered; iris yellow and bill creamy. Juvenile duller, more barred.

Races differ mainly in plumage coloration: *huttoni* much paler, lacking rufous morph, grey-brown above, whitish with black spots below; *latouchi* more strongly rufous; *hambroeki* with no rufous morph, dark brown above, prominent pale collar, buffish and finely streaked below, with very distinct pale facial disc and long bicoloured ear-tufts; *siamensis* dark; *vulpes* dark rufous with black markings above; *luciae* heavily marked and dark overall, no collar, rufous-brown to buff-brown with black bars above, well vermiculated below; *vandewateri* very dark brown to rufescent with prominent pale collar, blotchy dark markings above, finer scrawls below on rufescent or brown background; "*stresemanni*" rich rufous with white forehead and fine white speckles overall, no collar. VOICE. Very vocal. Clear, piercing, two-note whistle, "plew-plew" or "he-he", repeated every 5-10 seconds.

Habitat. Dense evergreen forest, especially with chestnut, oak and rhododendron, sometimes with pine; also montane forest, gullies and ravines; locally, exploits dense regrowth at forest edge. From foothills to 2600 m, occasionally to 2750 m.

Food and Feeding. Primarily moths, beetles, mantises, cicadas and other insects; also takes small rodents and birds, and perhaps lizards. Hunts mainly beneath canopy, in lower strata of dense vegetation; reported to keep close to ground. Strictly nocturnal; rarely seen by day.

Breeding. Little recorded information regarding breeding in all but India and Pakistan. Lays Mar-Jun in Pakistan to NE India. Nest in unlined hollow in tree trunk, either natural or an abandoned woodpecker or barbet hole, usually 2-7 m above ground. 2-3 (2-5) eggs; incubation and fledging periods unrecorded.

Movements. Sedentary in most of range, but descends into warmer valleys of Himalayas in winter.

Status and Conservation. Not globally threatened. CITES II. Reasonably common throughout range. Locally common from Pakistan across to Myanmar, but scarce in Bangladesh; described as relatively abundant in mountains of Thailand, and common in Malay Peninsula and S Vietnam, but uncommon in Borneo and Sumatra. Occurs in a series of protected areas throughout its range, such as Doi Chiang Dao Wildlife Sanctuary in N Thailand. Hsitou (Chitou) Forest Recrea-

tion Area in Taiwan. Kerinci-Seblat National Park in Sumatra and Mount Kinabalu National Park in Sabah, Borneo; frequently recorded at Fraser's Hill, peninsular Malaysia. Fairly adaptable; fact that species will occupy areas of dense regenerating growth at disturbed forest edge should aid its survival.

Bibliography. 8. Rajah Scops-owl

Otus brookii

French: Petit-duc radjah **German:** Radschaeule
Other common names: Brooke's/Rajah Brooke's Scops-owl

Spanish: Autillo Raja

Taxonomy. *Scops brookii* Sharpe, 1892, Mount Dulit, Sarawak, Borneo. Probably forms superspecies with *O. angelinae*. Has been considered conspecific with latter, but the two differ in morphology and possibly in behaviour. Two subspecies recognized.

Subspecies and Distribution.

O. b. solokensis (Hartert, 1893) - Sumatra.

O. b. brookii (Sharpe, 1892) - Borneo.

Specimen collected in E Java (Ijen) assigned to this species, but identity disputed; may belong to another species of *Otus*.

Descriptive notes. c. 23 cm. Brown overall; prominent ear-tufts with white on inner side; upperparts rusty-brown, heavily marked with dark bars and black streaks, with some cream spots; conspicuous white collars on hindneck and across mantle; scapulars with black-tipped white spots; breast lighter rufous and cream with black streaks; tarsus heavily feathered; iris yellow; bill and feet yellow. Distinguished from *O. bakkamoena* by yellow eyes, distinct double collar and larger size. Juvenile nominate undescribed. Race *solokensis* with more yellow tone to plumage; juvenile dark rufous and barred above, spotted below. **Voice.** Clear, monotonous note, described as explosive, "whaooo", followed by single or paired notes, repeated for up to 1 minute; also 2-4 "gwoou" notes, apparently in flight.

Habitat. Montane rainforest, primarily between 1200 m and 2400 m; perhaps only in the subtropical zones within its range.

Food and Feeding. Little information; primarily insects, especially Coleoptera and Orthoptera, also moths; once a frog.

Breeding. Parents accompanying 2 fledglings in Jul; no other information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Bornean Mountains EBA and Sumatra and Peninsular Malaysia EBA. Considered rare; possibly more widespread, but few observations within its known range. In Borneo, recorded only from Mt Dulit (Sarawak); in Sumatra, recorded from Gunung Kerinci and may possibly occur throughout the Barisan Range, but very few sightings and no indication that it is anything other than a very rare species. If Javan specimen of this species, then clearly extremely rare there, as no other records. Conservation status probably in need of revision.

Bibliography. Andrew (1992), Holmes (1996), MacKinnon (1988), MacKinnon & Philipps (1993), van Marle & Voous (1988), Marshall (1978), Smythies (1981), Stattersfield *et al.* (1998), Sujatnika *et al.* (1995), Tobias (1995).

9. Javan Scops-owl

Otus angelinae

French: Petit-duc de Java **German:** Angelinaeule **Spanish:** Autillo de Java
Other common names: Angelina's Scops-owl, Greater Sunda Scops-owl

Taxonomy. *Pisorhina angelinae* Finsch, 1912, Pangerango Mountain, 6000 feet [c. 2000 m], Java. Probably forms superspecies with *O. brookii*. Sometimes treated as conspecific with latter or with *O. spilocephalus* or, alternatively, as including race *vandewateri* of latter, but differs in morphology and also in far less vocal habits. Monotypic.

Distribution. W Java.

Descriptive notes. c. 16-18 cm; 70-90 g. Light rusty-brown facial disc, with prominent white eyebrows extending into ear-tufts; upperparts brown or rufous-brown, normally with rusty-buff hindneck-collar, and whitish scapular stripe; flight-feathers barred; underside whitish to pale buff with pronounced black streaks superimposed on faint rufous vermiculations; tarsus feathered to toes; iris golden-yellow; feet and bill yellowish-fleshy. Distinguished from *O. spilocephalus* by more prominent white eyebrows and ear-tufts, and golden rather than greenish-yellow iris. Juvenile somewhat darker and more barred and vermiculated, also with

yellowish markings on outer webs of primaries and yellowish bands on underside of tail. **Voice.** Far less vocal than *O. spilocephalus*, and often habitually silent. Main call, e.g. in alarm, an explosive "poo-poo" with short interval of c. 0.5 seconds between the notes, second note lower, repeated several times; contact call hissing "tch-tschschsch"; male also produces low, soft comfort call, "wook-wook".

Habitat. Frequents primary montane forest with well-developed understorey between 1500 m and 2500 m, but recorded as low as 1000 m; also seen in rainforest with upper canopy 40-55 m in height, and comprised of *Altingia*, *Quercus*, *Castanopsis* and *Ficus*. Prefers the lower and middle canopy layers, in which there is a wider variety of tree species. Occasionally roosts in rather exposed situations.

Food and Feeding. Primarily insects, including beetles, grasshoppers and crickets, and especially mantids; occasional reports of small lizards and snakes being taken. Snatches prey from trunk or foliage, or from ground.

Breeding. Families with two fledglings observed in Jul; no other information.

Movements. Sedentary.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in Java and Bali Forests EBA. Known only from two localities in W Java, Gunung Gede/Pangrango National Park and Gunung Tangkubanprahu. Considered rare by most authors, but in light of success obtained through mist-netting also speculated that it may be more common within its restricted range; this species' secretive behaviour and taciturn habits make any proper assessment of its population very difficult. Threats to its survival are unclear.

Bibliography. Andrew (1985, 1992), Andrew & Milton (1988), van Balen (1992), Becking (1994), Collar & Andrew (1988), Collar *et al.* (1994), Inskipp *et al.* (1996), Kuroda (1936), MacKinnon (1988), MacKinnon & Philipps (1993), Marshall (1978), Stattersfield *et al.* (1998), Sujatnika *et al.* (1995).

10. Mentawai Scops-owl

Otus mentawi

French: Petit-duc des Mentawai **German:** Mentawi-Zwergohreule **Spanish:** Autillo de las Mentawai
Other common names: Sipora Scops-owl

Taxonomy. *Otus bakkamoena mentawi* Chasen and Kloss, 1926, Sipora Island.

Probably forms superspecies with *O. bakkamoena*, *O. letitia*, *O. lempiji*, *O. semitorques*, *O. fuliginosus* and *O. megalotis*. Has sometimes been treated as conspecific with *O. bakkamoena*, *O. lempiji*, *O. sunia* or *O. manadensis*, but vocalizations distinct. Monotypic.

Distribution. Mentawai Is (Siberut to S Pagai), off W Sumatra.

Descriptive notes. 20 cm. Occurs in rufous-chestnut and blackish-brown morphs. Prominent ear-tufts and eyebrows whitish with dark mottles; upperparts with dark blotches and streaks; underparts paler, with black shaft streaks enclosing small whitish ocelli; tarsi feathered to toes; yellow iris; horn-coloured bill; grey toes. Lacks white collar of *O. bakkamoena*. Juvenile undescribed. **Voice.** Male gives series of "po-po" calls, ending in descending sequence of 7-8 "po" notes; also gruff honking noises, varying in pitch and inflection; duets, with female's higher-pitched quavering notes following male's "po-po..."

until songs synchronous, longest sequence c. 2 minutes.

Habitat. Lowland rainforest and secondary growth; sometimes near settlements; in villages, not infrequently perches on exposed branches.

Food and Feeding. Apparently insects.

Breeding. No information.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Status poorly known; appears to be rare and rather patchily distributed, but possibly locally common. Continuing destruction of forest habitat a likely threat, but species' apparent ability to tolerate human-altered habitats, e.g. villages and their surroundings, may aid its long-term survival.

Bibliography. Andrew (1992), Chasen & Kloss (1926), Deignan (1950b), Holmes, D.A. (1994a), Inskipp *et al.* (1996), MacKinnon & Philipps (1993), van Marle & Voous (1988), Marshall (1978), Riley (1929), Stattersfield *et al.* (1998).

11. Indian Scops-owl

Otus bakkamoena

French: Petit-duc à collier **German:** Indien-Zwergohreule **Spanish:** Autillo Indio
Other common names: Collared Scops-owl(!), Oriental Screech-owl

Taxonomy. *Otus bakkamoena* Pennant, 1769, Sri Lanka.

Probably forms superspecies with *O. mentawi*, *O. letitia*, *O. lempiji*, *O. semitorques*, *O. fuliginosus* and *O. megalotis*. Taxonomy complex and controversial, with various treatments by different authors: often considered to include one, or several, or all of above-mentioned species as races; sometimes regarded as conspecific with *O. lempiji*; or as monotypic, with all other currently recognized races placed with *O. letitia*; boundaries between all taxa poorly understood. Present treatment based mainly on vocalizations. Five subspecies recognized.

Subspecies and Distribution.

O. b. plumipes (Hume, 1870) - W Himalayas, from N Pakistan E to Nepal border.

O. b. deserticolor Ticehurst, 1922 - S Pakistan; possibly SE Iran; old record from Oman probably erroneous.

O. b. gangeticus Ticehurst, 1922 - NW India to lowland Nepal.

O. b. marathae Ticehurst, 1922 - C India, E to about S West Bengal.

O. b. bakkamoena Pennant, 1769 - SW & SE India and Sri Lanka.

Descriptive notes. c. 20 cm; male wingspan 60-5-61 cm, female 66 cm; 125-150 g. Occurs in grey-brown and rufous morphs; latter generally with distinct ochre tinge, commoner in S populations. Facial disc light greyish or rufous; forehead, eyebrows and conspicuous long ear-tufts much paler, whitish, with crown mottled blackish; upperparts mottled and spotted dark, with distinct buff collar on hindneck and another on nape, but indistinct scapular spots; underparts grey-buff to rufous-buff, with dark shaft streaks and vermiculations; iris generally brown; legs may be feathered to base of toes; bill and feet horn-coloured. Juvenile pale grey

to yellowish-brown, barred brown all over. Races vary in general coloration: *gangeticus* paler than nominate; *marathae* more grey, less rufous; *plumipes* somewhat darker; *deserticolor* much paler, pale sandy, with more golden eyes. Voice. Male gives quiet, frog-like, questioning "wuk?" or "whut?", repeated at irregular intervals, usually of 4-6 seconds; female call lower; rising series of chattering calls also heard.

Habitat. Forest, groves near towns and in cultivated areas, well-timbered gardens, orchards with shade trees; occasionally more open country with plenty of trees; also irrigated plantations and riverine forest in dry parts of Pakistan; noted nesting at edges of rubber and tea plantations in Sri Lanka. Nocturnal, hides in hollows or dense tree foliage during day. From plains up to c. 2130 m in Pakistan; to 1200 m in peninsular India, locally to 2400 m in E Himalayas; mostly lowlands and lower hills in Sri Lanka.

Food and Feeding. Primarily beetles, grasshoppers and other insects, including moth larvae; occasionally rodents, small birds and lizards, perhaps rarely bats.

Breeding. Lays Dec-May, mostly in later months, often during rainiest season in S of range; in Pakistan, nestlings found in Mar and Apr, also eggs in Apr. Nest generally in natural hollow in tree trunk, sometimes in abandoned building near habitation. 3-5 eggs; incubation possibly 25-27 days.

Movements. Resident in most of range; some movement to lower levels in winter, and variable nomadic movements according to food supply.

Status and Conservation. Not globally threatened. CITES II. Widespread and locally common; not really rare anywhere within range. Although rather retiring and rarely seen, described as common in Pakistan and Sri Lanka, frequent in Bhutan, locally common in Bangladesh, and at least locally common in India.

Bibliography. Ali (1996), Ali & Ripley (1981), Beaman (1994), Chakravarthy & Purna Chandra Tejasvi (1992), Daniels (1997), Deignan (1950b), Grimmett *et al.* (1998), Henry (1998), Hùe & Échécopar (1970), Inskipp *et al.* (1996), Khajuria (1970), Kotagama & Fernando (1994), Lamsfuss (1998), Marshall (1978), Mukherjee (1995), Phillips (1978), Ripley (1982), Roberts (1991), Roberts & King (1986), Roonwal (1950), Saha & Dasgupta (1992), Sugathan & Varghese (1996), Voous (1988), Wijesinghe (1994).

12. Collared Scops-owl

Otus lettia

French: Petit-duc indien **German:** Halsband-Zwergohreule **Spanish:** Autillo Chino
Other common names: Indian Scops-owl(!)

Taxonomy. *Scops lettia* Hodgson, 1836, Nepal. Probably forms superspecies with *O. mentawi*, *O. bakkamoena*, *O. lempiji*, *O. semitorques*, *O. fuliginosus* and *O. megalotis*. Previously considered a race of *O. bakkamoena*, including under synonyms *manipurensis* and *albioniger*, a treatment still preferred by many authors, and may intergrade with that species in Nepal; also, considered by some conspecific with *O. lempiji*. Differences in vocalizations, however, suggest specific status. Position of race *ussuriensis* unclear, but plumage features, eye colour and vocalizations close to *O. semitorques* and possibly better placed with latter; Indochinese population, tentatively included in nominate, may be closer to *erythrocampe*. Proposed race *aurorae* from N China included in *ussuriensis*. Five subspecies recognized.

Subspecies and Distribution.

O. l. lettia (Hodgson, 1836) - E Nepal, E India (West Bengal) and Bangladesh, E to Assam, Myanmar, Thailand (except S peninsula) and Indochina.
O. l. erythrocampe (Swinhoe, 1874) - SE China.
O. l. ussuriensis (Buturlin, 1910) - Sakhalin, Ussuriland and NE China.
O. l. glabripes (Swinhoe, 1870) - Taiwan.
O. l. umbratilis (Swinhoe, 1870) - Hainan I.

Descriptive notes. 23-25 cm; 100-170 g. Occurs in grey-brown and rufous morphs. Facial disc greyish to light rufous, with buff eyebrows and inner webs of ear-tufts, latter rather small but conspicuous when raised; upperside grey-brown or rufous-brown, dark-mottled and with few whitish spots, and pale collar on back of neck; chin and throat pale, barred or mottled with black, breast pale greyish-buff or rufous with black streaks; tarsus feathered; iris yellowish-brown; bill green to horn with blackish tip, lower mandible yellow; feet and claws fleshy-grey to dark olive. Differs from similar *O. semitorques* in eye colour and voice.

Juvenile more barred. Races not very well marked: *erythrocampe* generally less grey, more brown and buff, with dark yellow to golden-brown eyes; *glabripes* paler, *umbratilis* darker; *ussuriensis* with orange tinge to eyes. Voice. Male gives single mellow "buoo", inflected downwards, repeated at longish intervals of 12-20 seconds; female similar but higher-pitched, more mewing; courtship duets can continue for 15 minutes or longer. Also chattering series in alarm. Race *ussuriensis* said to give "koog koog" call at extremely long intervals in breeding season.

Habitat. Sal, deciduous and evergreen forest, secondary growth, also open scrub near cultivation, open areas with stands of trees and bamboo, and gardens in towns and villages; open mixed forest with moderate understorey in E Russia. Considered primarily a submontane species in E Himalayas, where occurs at up to 2400 m, but elsewhere in range equally frequent from lowland plains to at least 2200 m.

Food and Feeding. Insects (especially beetles and grasshoppers); diet also includes moderate proportion of vertebrates, such as rodents, small birds and lizards. In NE of range, breeding-season concentrations of these owls in areas with rodent plagues indicate that small mammals taken locally in large numbers.

Breeding. Feb-Apr/May; some evidence that breeding season may be longer; in Ussuriland, young leave nest in Jul. Nest a natural hollow or woodpecker hole 2-5 m from ground, sometimes higher, in either living tree trunk or, perhaps more commonly, a snag. Usually 3-5 eggs; reported that both parents may share in incubation duties.

Movements. Generally resident, with some local movement from higher-lying areas to lower levels in winter. Many individuals of N populations (*ussuriensis*) migrate in autumn to Korea and N China, some possibly moving farther S; recorded as vagrant in Japan (Honshu).

Status and Conservation. Not globally threatened. CITES II. Described as very common in parts of range, e.g. Thailand and Myanmar, and locally frequent in E Himalayas; race *ussuriensis* said to be rather scarce. Does not shun man's presence, and appears able to live in association with agricultural development, so long as some trees available; by no means uncommon in suburban areas, and also tolerates more urbanized habitats in places. No obvious threats.

Bibliography. Ali (1996), Ali & Ripley (1981), Ali *et al.* (1996), Deignan (1950b), Échécopar & Hùe (1978), Flint *et al.* (1984), Grimmett *et al.* (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Knystautas

(1993), Majumdar *et al.* (1992), Marshall (1978), Ripley (1982), Smythies (1986), Stepanyan (1990, 1995), Voous (1988), Zhao Zhengjie (1995).

13. Sunda Scops-owl

Otus lempiji

French: Petit-duc de Horsfield **German:** Sunda-Zwergohreule **Spanish:** Autillo de la Sonda
Other common names: Collared Scops-owl(!)

Taxonomy. *Srix* [sic] *Lempiji* Horsfield, 1821, Java.

Probably forms superspecies with *O. mentawi*, *O. bakkamoena*, *O. lettia*, *O. semitorques*, *O. fuliginosus* and *O. megalotis*. Frequently treated as race of *O. bakkamoena*, and sometimes considered to include as race or to be conspecific with *O. lettia*, but vocalizations distinct. Race *cnephaeus* apparently differs vocally, may be separate species; *condorensis* doubtfully distinct from nominate. Six subspecies recognized.

Subspecies and Distribution.

O. l. condorensis Kloss, 1930 - S peninsular Thailand below Isthmus of Kra.
O. l. lempiji (Horsfield, 1821) - Malay Peninsula (except S), S Sumatra, Bangka, Belitung, Java, Bali, N Natuna Is, Borneo (except N).
O. l. cnephaeus Deignan, 1950 - S Malay Peninsula.
O. l. hypnoides Deignan, 1950 - N & C Sumatra.
O. l. lemorum Deignan, 1957 - N Borneo.
O. l. kangeanus Mayr, 1938 - Kangean Is.

Descriptive notes. c. 20 cm; 100-120 g. Occurs in grey-brown and rufous morphs. Facial disc greyish to light rufous-buff with blackish border; buffy-whitish forehead, eyebrows and long ear-tufts, latter edged black, contrast sharply with blackish to dark brown crown; upperparts dull brown to greyish, densely marked with black blotches and buff spots, with indistinct pale buff or sandy nuchal collar; underparts buffy grey-brown to cinnamon, with dark shaft streaks and thin broken vermiculations; tarsus fully feathered; iris dark brown, but said rarely to be bright yellow; bill and feet ivory-white to pale yellow. Differs

from very similar *O. semitorques* in eye colour and voice. Juvenile generally more brownish-buff and more barred, especially on crown. Races poorly defined: *hypnoides* tends to be darker, especially rufous morph; *cnephaeus* somewhat smaller and with different call. Voice. Male utters soft, upward-inflected "wooup", repeated at intervals of 10-15 seconds, often continued for several periods; female similar, but slightly higher-pitched; duets in breeding season, with all calls equally spaced. Race *cnephaeus* said to give uninflected call, with intervals between calls longer.

Habitat. Second-growth evergreen and deciduous forest, forest edge, plantations, open areas with scattered trees, parks, villages, well-wooded gardens, and tree-lined suburban and urban streets; adaptable, readily accepts human-altered habitats; avoids primary forest. From sea-level to 1000 m, occasionally to 1600 m, locally to c. 2000 m.

Food and Feeding. Mostly insects, especially large beetles, Orthoptera, Lepidoptera and mantids; occasionally small birds, e.g. munias (*Lonchura*), perhaps mainly nestlings, and mice. Hunts from a perch, including roof of house or village hut, dropping on to prey on or near ground.

Breeding. Lays mainly Jan-Apr, occasionally later; fledgling just off nest in mid Jun in Borneo. Nest in natural hole in tree, sometimes in other hollow area formed by e.g. dead palm leaves; nest also recorded in uninhabited houses. 2 eggs, rarely 3; chick down white (Malay Peninsula), greyish (Java) or rufous.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Considered common in Malaysia and fairly common to very common throughout Greater Sundas. In some parts of its range, such as Sumatra, described as the most common strigid; no reports indicating population declines or scarcity. Apparent attraction to cultivations and human-populated areas advantageous to its survival; would appear to benefit from conversion of forested land to agricultural uses, enabling possible range expansion.

Bibliography. Bucknill & Chasen (1990), Deignan (1945, 1950b), Delacour (1947), Glenister (1951), Hellebrekers & Hoogerwerf (1967), Hoogerwerf (1949a), Inskipp *et al.* (1996), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillips (1993), Madoc (1976), van Marle & Voous (1988), Marshall (1978), Medway & Wells (1976), Mees (1986), Riley (1938), Roonwal (1950), Smythies (1981, 1986), Voous (1988), Wells (1999).

14. Japanese Scops-owl

Otus semitorques

French: Petit-duc du Japon **German:** Japan-Zwergohreule **Spanish:** Autillo Japonés

Taxonomy. *Otus semitorques* Temminck and Schlegel, 1844, Kyushu, Japan.

Probably forms superspecies with *O. mentawi*, *O. bakkamoena*, *O. lettia*, *O. lempiji*, *O. fuliginosus* and *O. megalotis*. Formerly treated as subspecies of highly variable *O. bakkamoena*, but significant differences in vocalizations, as well in eye colour, indicate separate species. Sometimes considered to include race *ussuriensis* of *O. lettia*, which closer to present species in voice and plumage characters, and also intermediate in eye colour; possibly better included as race of present species. Two subspecies recognized.

Subspecies and Distribution.

O. s. semitorques Temminck & Schlegel, 1844 - S Kuril Is (Urup S to Kunashir), and Hokkaido S to Yakushima, including Sado, Tsushima, Goto Is and Yakushima.
O. s. pryeri (Gurney, 1889) - S Izu Is (Hachijo) and S Ryukyu Is (Okinawa to Iriomote).

Descriptive notes. 23-25 cm; wingspan 60-66 cm; c. 130 g. Relatively long, pointed wings, with primary P7 longest. Facial disc pale grey-brown with dark speckles; eyebrows and prominent ear-tufts whitish; upperparts grey-brown, tinged sandy, with coarse blackish and buff markings; well-defined lighter nuchal band, with less distinct pale occipital patch above it; flight-feathers brown with light pale bars, tail with 7-8 dark brown marbled bands; chin and sides of throat sometimes whitish; underparts light greyish-buff, streaked dark, and with delicate transverse pencil-lines; tarsi and toes feathered; iris orange to red. Differs from *O. bakkamoena*, *O. lettia* and *O. lempiji* in wing shape and length, red eyes and voice; extremely similar to race *ussuriensis* of *O. lettia*, but somewhat darker. Juvenile greyish-buff and distinctly barred all over. Race *pryeri* less grey, more rusty-coloured, toes unfeathered, eyes orange-yellow. Voice. Male gives deep "whook", regularly

repeated at long intervals; many other calls described, e.g. "koo" or "kwe" notes, also repeated "kwee-kwee" or "pew-u, pew-u".

Habitat. Lowland forest, wooded plains and forested hillsides, up to 900 m above sea-level; in winter, also parks and gardens, including those in towns and cities.

Food and Feeding. Mostly insects, small rodents (especially voles and mice) and spiders; occasionally takes small birds, frogs, lizards and crustaceans.

Breeding. Lays May-Jul. Nest in natural tree cavity; 4-5 eggs. Incubation and fledging periods not reported.

Movements. Resident, nomadic and migratory; moves to lower altitudes in winter. Autumn influx in SE Hokkaido, presumably of birds from Kurils; other N birds may move S to plains, coastal areas or even cities; winter visitor to S coastal regions of Honshu, e.g. to Tokyo area during Oct-Mar and to Yamanashi-ken during Nov-Apr.

Status and Conservation. Not globally threatened. CITES II. Locally common; very common in Tsushima; fairly common in Kyushu, Shikoku, Honshu and Sado; less common in Hokkaido. Race *pyerri* poorly known; although reported as abundant in Iriomote, this not substantiated by later observations. No obvious threats, and appears able to live in proximity to man.

Bibliography. Austin & Kuroda (1953), Brazil (1991), Brazil & Yamamoto (1989a), Deignan (1950b), Flint *et al.* (1984), Higuchi & Momose (1980), Marshall (1978), Sonobe (1982), Stepanyan (1990), Voous (1988), Zhao Zhengjie (1995).

15. Palawan Scops-owl

Otus fuliginosus

French: Petit-duc de Palawan **German:** Palawan-Zwergohreule **Spanish:** Autillo de Palawan

Taxonomy. *Scops fuliginosa* Sharpe, 1888, vicinity of Puerto Princesa, Palawan.

Probably forms superspecies with *O. mentawi*, *O. bakkamoena*, *O. lettia*, *O. lempiji*, *O. semitorques* and *O. megalotis*. Formerly treated as subspecies of *O. bakkamoena*, but vocalizations distinct from latter's. Monotypic.

Distribution. Palawan I, in SW Philippines.

Descriptive notes. c. 19-20 cm. Conspicuous ear-tufts; light rufous facial disc; upperparts dark reddish-brown, finely vermiculated black; reduced pale collar on hindneck; pale buffy-brown to chestnut below, with dark streaks and vermiculations; iris pale orange-brown to yellowish-ochre; bill horn; bare toes greyish-yellow. Lacks chestnut on back, otherwise closely resembles the larger *O. mentawi*; differs from *O. megalotis* in smaller size, less prominent nuchal collar. Juvenile undescribed. **Voice.** Male call described as deep, croaking rasp, "krarr-kuarr", repeated at short intervals.

Habitat. Lowland forest, and mixed cultivation with trees.

Food and Feeding. No information; presumably insects.

Breeding. No information.

Movements. Sedentary.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species; present in Palawan EBA. Said to be very rare. Most recent records from St Paul Subterranean National Park, where perhaps locally not uncommon, and from Iwahig and Balsahan. Threatened by lowland deforestation, which is increasing in extent on Palawan.

Bibliography. Anon. (1997b), Collar *et al.* (1994), Deignan (1950b), Dickinson *et al.* (1991), Inskipp *et al.* (1996), Marshall (1978), McGregor (1909-1910), duPont (1971), Stattersfield *et al.* (1998), Voous (1988).

16. Philippine Scops-owl

Otus megalotis

French: Petit-duc de Luzon **German:** Philippinen-Zwergohreule **Spanish:** Autillo Filipino
Other common names: Whitehead's Scops-owl, Luzon Collared Scops-owl

Taxonomy. *Scops megalotis* Walden, 1875, probably Manila.

Probably forms superspecies with *O. mentawi*, *O. bakkamoena*, *O. lettia*, *O. lempiji*, *O. semitorques* and *O. fuliginosus*. Older name *O. whiteheadi* sometimes still used, now rejected. Formerly treated as conspecific with *O. bakkamoena*, but shown to be vocally distinct. Race *boholensis* doubtfully distinct from *everetti*. Four subspecies recognized.

Subspecies and Distribution.

O. m. megalotis (Walden, 1875) - Luzon, Marinduque and Catanduanes.

O. m. everetti (Tweeddale, 1879) - Samar, Biliran, Leyte, Mindanao and Basilan.

O. m. nigrorum Rand, 1950 - Negros.

O. m. boholensis McGregor, 1907 - Bohol.

Descriptive notes. 23-28 cm; c. 200-300 g. With *O. sagittatus*, the largest of the Old World scops-owls. Occurs in grey-brown and rufous morphs. Grey-brown morph deep brown or brownish-olive above with buff vermiculations, black-tipped pale feathers on hindneck forming collar, whitish eyebrows, underparts buffish-grey with some broad black shaft markings and few thin cross-lines; rufous phase brownish-red above, generally buffy-yellow below; both morphs with barred wings and tail; tarsus feathered to toes; iris golden-brown or orange-brown; bill light brown, tipped with white; feet dull white to yellow-brown. Differentiated from *O. bakkamoena* by comparatively larger size. Juvenile similar to respective adult morph but more barred, rufous morph more deeply cinnamon than adult. Race *everetti* smaller than nominate, with tarsal feathering stopping short of foot; *nigrorum* very distinct and smaller still, with bright rusty head and whiter underparts. **Voice.** A loud, sudden series of 3-6 ascending notes on falling scale, similar to *O. lempiji* call but notes longer; also powerful "oik oik oik oik", with marked interval between each note.

Habitat. Tropical forest and secondary woodland, generally in denser parts; occurs mostly up to c. 1200 m, but in SE Luzon noted between 450 m and 1550 m on Mt Isarog. Noted roosting among root system of partly upturned dead tree.

Food and Feeding. Stomach contents revealed only insects.

Breeding. Males captured in Mar in or approaching breeding condition; young fledgling in Feb in Luzon; juveniles in May in Negros, estimated to have hatched Jan-Feb; possibly lays from Dec/Jan onwards. Possibly 3-4 eggs, but family party with just 1 young recorded.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Few reliable data. Reports vary from probably endangered to widely distributed (on Mt Isarog), but very little is known about this species. May be found to be locally

common. Since it appears to prefer densely wooded habitats, forest clearance and destruction presumably a threat at least in some parts of range.

Bibliography. Amadon & duPont (1970), Brooks, Evans *et al.* (1992), Brooks, Dutton *et al.* (1996), Danielsen *et al.* (1994), Deignan (1950b), Delacour & Mayr (1946), Dickinson, Kennedy & Parkes (1991), Dickinson, Kennedy, Read & Rozendaal (1989), Gilliard (1950a), Goodman & Gonzales (1989, 1990), Inskipp *et al.* (1996), Marshall (1978), McGregor (1909-1910), Oliver & Wirth (1996), duPont (1971), duPont & Rabor (1973b), Rabor (1938a, 1977), Rand (1950), Rand & Rabor (1960), Voous (1988).

17. Wallace's Scops-owl

Otus silvicola

French: Petit-duc de Wallace **German:** Wallace-Zwergohreule **Spanish:** Autillo de Wallace
Other common names: Flores(!)/(Lesser) Sunda Scops-owl(!)

Taxonomy. *Scops silvicola* Wallace, 1864, Flores.

Relationships unclear; probably closest to the *O. bakkamoena* superspecies. Monotypic.

Distribution. Sumbawa and Flores, in Lesser Sundas.

Descriptive notes. c. 23-25 cm. Facial disc fairly uniform tan, with paler eyebrows; long ear-tufts mottled brown and buff; upperparts olive-brown, lightly vermiculated buffy-tan, with dark brown shaft streaks throughout; flight-feathers brown, with white bars darkening to tan near tips; tail finely barred buff; underparts barred brown and buffish-tan, with dark brown drop-like streaks, and diagnostic white patch across upper breast; tarsus feathered white to toes; dull orange-yellow eyes and yellow to greyish bill. Relatively similar to *O. semitorques*. Juvenile generally paler, more rufous, with less distinct patterning. **Voice.** Territorial call steady series of c. 10 (up to 18) deep "whumph" notes on same pitch; at dawn, 4-5 songs at 3-minute intervals; also gruff "row" call, repeated irregularly.

Habitat. Semi-evergreen rainforest, forest edge, and submontane forest with bamboo thickets; more rarely moist deciduous forest, also wooded areas around farms; locally in urban areas, e.g. recorded in town of Ruteng, on Flores. From 350 m to 1600 m.

Food and Feeding. No information.

Breeding. Virtually unknown; probably lays during May.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Northern Nusa Tenggara EBA. Currently considered Near-threatened. Probably under-recorded; considered common. Fairly adaptable, and able to live in variety of habitats, but appears to be most numerous in semi-evergreen forest below 1450 m; this habitat increasingly scarce, and forest destruction thus a long-term threat.

Bibliography. Andrew (1992), Buck (1988), Butchart *et al.* (1993, 1996), Coates & Bishop (1997), Holmes (1993), Jepson & Monk (1995), Johnstone *et al.* (1996), Marshall (1978), Paynter (1963), Rensch (1931), Stattersfield *et al.* (1998), Sujatnika *et al.* (1995), White & Bruce (1986).

18. Mindanao Scops-owl

Otus mirus

French: Petit-duc de Mindanao **German:** Mindanaoeule **Spanish:** Autillo de Mindanao

Taxonomy. *Otus scops mirus* Ripley and Rabor, 1968, Hilong Hilong Peak, Agusan Province, Mindanao.

Probably forms superspecies with *O. longicornis*. Formerly treated as race of either *O. sunia* or *O. scops*, but differs greatly from both in morphology and vocalizations. Monotypic.

Distribution. Mindanao I, in S Philippines.

Descriptive notes. 19-20 cm. A dark, boldly marked species. Facial disc pale greyish-brown with indistinct rings; eyebrows and inner part of smallish ear-tufts whitish; upperparts greyish-brown, heavily blotched blackish and lightly with rufous; white spots form conspicuous hindneck-collar; partly white scapulars form fairly prominent line; wings and tail prominently barred; underparts mainly white with strong pattern of heavy black lines and finer cross-lines; tarsus bare for distal third; iris brown to yellow; bill greenish-grey; lower tarsus and toes grey to pale yellow-grey. Juvenile unknown. **Voice.** Said to utter soft double

notes, recalling pigeon or dove (Columbidae).

Habitat. Montane rainforest.

Food and Feeding. No information.

Breeding. No information.

Movements. Presumably resident.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in Mindanao and the Eastern Visayas EBA. Apparently rare in restricted range, and very few observations. Recorded only from Mt Apo and Mt Hilong-Hilong, and more recently from Mount Katanglad National Park and Sitio Siete. Continuing forest destruction at all three localities must pose serious threat to its survival.

Bibliography. Anon. (1997b), Collar *et al.* (1994), Dickinson *et al.* (1991), Inskipp *et al.* (1996), Marshall (1978), Ripley & Rabor (1968), Stattersfield *et al.* (1998).

19. Luzon Scops-owl

Otus longicornis

French: Petit-duc longicorne

German: Luzoneule

Spanish: Autillo de Luzón

Other common names: Luzon Slender-billed Scops-owl

Taxonomy. *Scops longicornis* Ogilvie-Grant, 1894, mountains of northern Luzon.

Forms part of assemblage referred to as subgenus *Otus*. Probably forms superspecies with *O. mirus*. Previously treated as race of *O. scops* or *O. spilocephalus*, but differs from both in morphology and apparently in vocalizations. Monotypic.

Distribution. Luzon, in N Philippines.

Descriptive notes. c. 19 cm. Frosted facial trim, white eyebrows, long loreal plumes barred white with black tips, long ear-tufts with some rufous colouring, ear-coverts barred white, blackish-brown and rufous; pale or white collar, narrower on hindneck than on breast; upperparts bright rufous-buff, streaked and with irregular dark bars on each feather; chin and throat whitish, throat feathers tipped with black; breast rufous, mottled with black and white, rest of underparts white with fulvous and rusty-brown mottling; tarsus feathered for roughly half length; iris yellow; bill slender, laterally compressed, dull green; lower tarsus

and toes whitish-flesh. Juvenile not described. **VOICE.** Said to give an odd, whistling "quop".

Habitat. Humid forest, generally in foothills and mountains, also in pine woodland; specimens collected from 360-1800 m; recently observed in lower montane forest at 700-1500 m.

Food and Feeding. Stomach contents included primarily insects.

Breeding. Nest with 3 chicks in May. Nest in tree hole. 2-3 eggs; chick with light grey down, this replaced by brown-barred grey.

Movements. Presumably resident.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in Luzon EBA. Evidently rare, and few reliable sightings. Recent records from Quezon National Park, near

Manila, and from Mt Cetaceo and Mt Dimalayag in Sierra Madre, in NE Luzon. Rarity attributed to habitat loss, and this seems likely to continue. Research needed on species' ecology and biology, in order to determine its conservation requirements.

Bibliography. Amadon & duPont (1970), Anon. (1997b), Collar *et al.* (1994), Danielsen *et al.* (1994), Dickinson *et al.* (1991), Goodman & Gonzales (1990), Hachisuka (1934), Inskipp *et al.* (1996), Marshall (1978), McGregor (1904, 1909-1910), Ogilvie-Grant (1894), Poulsen (1995), Stattersfield *et al.* (1998).

20. Mindoro Scops-owl

Otus mindorensis

French: Petit-duc de Mindoro

German: Mindoroeule

Spanish: Autillo de Mindoro

Taxonomy. *Scops mindorensis* Whitehead, 1899, highlands of Mindoro.

Relationships uncertain, but resembles some taxa of *O. mantananensis*. Formerly treated as race of *O. scops* or *O. sunia*, but very different from both in morphology. Birds in lowlands of W Mindoro recently attributed to this species, but differing vocally from other populations, now shown to be race *mindorensis* of *Ninox philippensis*. Monotypic.

Distribution. Mindoro, in NC Philippines.

Descriptive notes. 18-19 cm. Small, with overall plumage dull and finely marked; ear-tufts of moderate length and blotchy; upperparts brown with vague fine darker streaking and vermiculations; mainly buffy below with narrow dark streaks and inconspicuous dark and white barring; tertials essentially unbarred, while tail is narrowly banded; tarsi half feathered; claws small, weak, pale. Juvenile undescribed. **VOICE.** Male's call a short hoot, "who", repeated in series with intervals of 5 seconds or more.

Habitat. Montane forest above 870 m; roosts by day in dense foliage or in tree cavity.

Food and Feeding. Mostly insects.

Breeding. Type specimen, collected in Jan, had well-developed eggs; no other information.

Movements. Resident.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in Mindoro EBA. Apparently quite common in suitable habitat; in some areas, individuals spaced at no more than c. 150 m. Montane forest now greatly diminished in size, however, and confined to elevations above 870 m; continuing clearance operations reducing area of suitable habitat even further.

Bibliography. Anon. (1997b), Collar & Andrew (1988), Collar *et al.* (1994), Dickinson *et al.* (1991), Dutson *et al.* (1992), Evans, Dutson & Brooks (1993), Inskipp *et al.* (1996), Marshall (1978), McGregor (1909-1910), Oliver & Wirth (1996), Stattersfield *et al.* (1998).

21. Pallid Scops-owl

Otus brucei

French: Petit-duc de Bruce **German:** Streifenohreule **Spanish:** Autillo Persa
Other common names: Striated/Bruce's Scops-owl, Desert Screech-owl

Taxonomy. *Ephialtes Brucei* Hume, 1873, Rahuri, Ahmednagar, Maharashtra. Probably forms superspecies with *O. senegalensis*, *O. scops*, *O. sunia* and *O. flammeolus*. Has often been considered race of *O. scops* or *O. sunia*, but significant differences in voice and morphology, and no hybridization in areas of range overlap. Socotran form *socotranus* and Arabian *pamelae* currently placed with *O. senegalensis*, but sometimes included with present species, or may be specifically distinct. Geographical boundaries of races unclear, with apparent intergradation, and individuals showing intermediate characters (e.g. between *obsoletus* and *exiguus*); Turkish birds sometimes placed in *exiguus*; *obsoletus* and *semenowi* sometimes considered only intergrades between races. Four subspecies recognized.

Subspecies and Distribution.

O. b. brucei (Hume, 1873) - E Aral Sea to Kirgizia and Tajikistan.
O. b. obsoletus (Cabanis, 1875) - S Turkey, N Syria, N Iraq, Turkmeniya, Uzbekistan and N Afghanistan.
O. b. semenowi (Sarudny & Härms, 1902) - S Tajikistan and W China (E to C Tarim Basin) S to E Afghanistan and N Pakistan.
O. b. exiguus Mukherjee, 1958 - Israel (extinct as breeder), C & E Iraq, S Iran, Oman, S Afghanistan, W Pakistan.

Descriptive notes. 21 cm; wingspan 54-64 cm; c. 100-110 g. Pale scops-owl with distinct fine streaking and short ear-tufts. Facial disc pale buffish-white, with thin dark border and short whitish eyebrows; upperparts light greyish-brown with yellowish tinge, with sparse and fine black streaks, broader on crown and forehead, nape with light ochre patch, scapulars with blackish-edged white feathers; flight-feathers and tail thinly barred; below, paler and more heavily streaked with black, especially on centre of breast; tarsus fully feathered to base of toes; iris yellow; bill brownish-horn, yellowish at base of lower mandible; feet grey; claws dark horn, occasionally described as lead-coloured. Distinguished from all races of *O. scops* by paler appearance, plainer upperparts, lack of rufous coloration, absence of transverse patterning below. Juvenile paler, narrowly barred creamy and grey, shorter ear-tufts. Races differ mainly in plumage coloration, but much overlap: *semenowi* similar to nominate, but deeper ochre-yellow, streaks sometimes broader; *obsoletus* more sandy-buff, streaks narrower but sharp; *exiguus* greyer, streaks below weaker, more diffuse. Voice. Male territorial call a long series of low, hollow "whoop" or "who" notes, similar to those of Stock Dove (*Columba oenas*), at rate of 5-8 per 5 seconds; also short barking calls.

Habitat. Semi-open areas with trees and bushes, including cultivation, palm groves, orchards, riverine woodland; also parks, large gardens in towns; generally in more arid areas than *O. scops*, and in Pakistan in semi-desert and stony foothills, rocky gorges and similar arid habitats; on migration and in winter, also in acacias in desert. Mostly lowlands, but to 1800 m in Pakistan; tends to avoid mountains in WC Asia.

Food and Feeding. Insects, such as beetles, moths, locusts and mole-cricket (Gryllotalpidae), and spiders; also small mammals (rodents, shrews, bats), birds (especially small passerines), lizards; prey choice probably dependent on availability. Hunts from perch, dropping down to take prey from branch or ground; also pursues and catches aerial prey, such as moths and bats, on the wing. Sometimes forages in morning or afternoon.

Breeding. Pairing begins on arrival in N parts of range, usually Mar; lays Apr-May in most of range, to Jun in Uzbekistan. Very vocal during breeding season. Nest 3-6.5 m above ground in hollow tree, particularly poplar (*Populus*), willow (*Salix*) or mulberry (*Morus*), in old woodpecker hole, or in cavity in bank, wall, cliff or building; also in nestbox; often uses Magpie (*Pica pica*) nests locally, e.g. in Uzbekistan, 4-6 eggs; incubation 26-28 days; hatching asynchronous, chick with white down; fledging period 28-30 days. In Uzbekistan, from 18 eggs in 4 nests, 6 young fledged.

Movements. Resident and migratory. Apparently resident in Iran, and thought primarily resident in Pakistan. Extent of movements uncertain in some areas, e.g. possibly only summer visitor in Turkey; probably partial migrant in Iraq, normally encountered Mar-Oct only. Migratory in NE of range, arriving late Mar or Apr and leaving Sept/Oct; recorded in China Apr-Oct. Scarce migrant and winter visitor in S Israel; rare visitor in India.

Status and Conservation. Not globally threatened. CITES II. Status not well known. Common in Iraq; scarce in Pakistan. Recorded densities in NE of range low, e.g. from 2 pairs/2.5 km² to 10-12 pairs/400 km². May be reasonably common in much of range, but few data. No known threats.

Bibliography. Ali & Ripley (1981), Aspinall (1996), Beaman (1994), Beaman & Madge (1998), van den Berg *et al.* (1988), Cramp (1985), Etchécopar & Hùe (1964, 1978), Evans (1994), Flint *et al.* (1984), Fry *et al.* (1988), Goodman *et al.* (1989), Grimmett *et al.* (1998), Hùe & Etchécopar (1970), Jennings (1995), Kemp & Kemp (1998), Knystautas (1993), Mendelsohn (1996), Mikko (1983), Mukherjee (1995), Paz (1987), Porter, Christensen & Schiermacker-Hansen (1996), Ripley (1982), Roberts (1991), Roberts & King (1986), Shinhai (1993, 1996), Snow & Perrins (1998), Stepanyan (1990), Voous (1988), Zhao Zhengjie (1995).

22. African Scops-owl

Otus senegalensis

French: Petit-duc africain **German:** Afrika-Zwergohreule **Spanish:** Autillo Africano

Taxonomy. *Scops Senegalensis* Swainson, 1837, Gambia. Probably forms superspecies with *O. brucei*, *O. scops*, *O. sunia* and *O. flammeolus*. Formerly considered conspecific with *O. scops*, but separated specifically on basis of differences in voice, plumage and size. Races *socotranus* and *pamelae* sometimes placed with *O. brucei*, but closer to present species, or may even be specifically distinct. Several additional races described on basis of differences in plumage, morphology and/or size: populations from C Ethiopia to Somalia and N Kenya, from NE Zaire and W Uganda, and from Swaziland and E Cape Province sometimes separated as, respectively, *caecus*, *ugandae* and *latipennis*, but probably only colour morphs; birds described

from S Sudan and NW Ethiopia (*pygmaea*), E Kenya and Tanzania (*graueri*), Angola E to Malawi (*hendersonii*), E Malawi to N Mozambique (*pasilus*) and Namibia to N Natal and S Mozambique (*intermedius*) poorly differentiated and seem to fall within range of variation of nominate. Five subspecies currently recognized.

Subspecies and Distribution.

O. s. senegalensis (Swainson, 1837) - from Senegal and Sierra Leone E to NW Ethiopia and Somalia, S (except in SE Kenya) to SE South Africa.
O. s. pamelae Bates, 1937 - S Saudi Arabia.
O. s. socotranus (Ogilvie-Grant & Forbes, 1899) - Socotra I.
O. s. feae (Salvadori, 1903) - Annobon I (Pagalu), in S Gulf of Guinea.
O. s. nivosus Keith & Twomey, 1968 - SE Kenya (lower Tana R to Lali Hills).

Descriptive notes. 16-19 cm; wingspan c. 40-45 cm; 45-123 g. Occurs in grey-brown and rufous-brown morphs. Greyish facial disc bordered by black, with short white eyebrows and white-edged ear-tufts; dark grey-brown or rufous-brown above, streaked and mottled with black, streaks broader on crown; often rufous-buff on neck and wing-coverts; scapulars boldly white-spotted; flight-feathers and tail well barred; underparts finely vermiculated with narrow dark shaft streaks; iris yellow; bill dark horn; feet greyish. Juvenile similar to adult, but washed with brown. Races well differentiated: *feae* much darker, with rusty feather edges.

streaks broad and heavy; *socotranus* pale grey-brown, poorly marked above; *pamelae* pale brownish-grey and whitish, often rufous tinge on wing-coverts, broader white eyebrows; *nivosus* paler still, grey and white, with lower underparts plain white. Voice. Short purring, frog-like trill, "krrrup", repeated at intervals of 5-10 seconds for long periods; female slightly higher-pitched. Socotran birds said to utter quiet introductory "woup-woup".

Habitat. Wooded savanna, dry, open woodland, forest clearings, park-like habitats, bushveld, and acacia scrub; also large gardens with tall trees, and in W Africa occasionally mangroves. Roosts during day in dense foliage and alongside open trunks and branches, using favoured sites for weeks on end. From sea-level to 2000 m.

Food and Feeding. Mostly insects, including beetles, mantids, crickets and grasshoppers, and cockroaches, and spiders and scorpions; prey delivered to nest also include small vertebrates, with small numbers of geckos and lizards, frogs, and more rarely small mammals and birds (small passerines). Dietary habits similar to those of *O. scops*. Hunts by dropping on to prey from perch. Occasionally hunts on foot; also observed foraging along dead tree trunk and pulling at bark to capture a moth and woodlouse, and foraging along rocks in dry river to capture a millipede. Most prey caught on ground, but insects often seized in flight. Probably hunts within 500 m of nest. Strictly nocturnal.

Breeding. Lays generally at start of rains: Feb-Mar and Sept in W Africa, Apr-May in Sudan, Aug-Dec in E Africa, mainly Aug-Nov (peak Oct) in S Africa. Monogamous. Solitary, but occasionally pairs in close proximity, still territorial. Nest in small cavity in tree, including old woodpecker hole, or in broken tree top, up to 10 m above ground; in Namibia, once in side of old stick nest of Lappet-faced Vulture (*Torgos tracheliotus*). 2-4 eggs, usually 3; incubation 20-24 days; chick with whitish-grey down; young brooded until c. 12 days, leave cavity at c. 26 days.

Movements. Little information. Some evidence that birds from S of Limpopo R may move N into Zimbabwe in winter.

Status and Conservation. Not globally threatened. CITES II. Generally common throughout range, and locally very common, especially in wooded savanna, where up to 12 individuals heard from single spot. Widespread in S Africa; considered rare in E Cape. Occurs in a considerable number of protected areas in most countries throughout its extensive range. Secretive habits make any accurate assessment of numbers difficult.

Bibliography. Ash & Miskell (1998), Bannerman (1953), Barlow *et al.* (1997), Beaman (1994), Benson & Benson (1977), Benson *et al.* (1971), Brown *et al.* (1987), Cave & Macdonald (1955), Cheke & Walsh (1996), Dixon (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elglood *et al.* (1994), Field (1998), Friedmann (1930), Fry *et al.* (1988), Gallagher (1986), Gatter (1997), Ginn *et al.* (1989), Giraudoux *et al.* (1988), Gore (1990), Grimes (1987), Harrison *et al.* (1997), Jennings (1995), Keith & Twomey (1968), Kemp & Calburn (1987), Kemp & Kemp (1998), Lewis & Pomeroy (1989), Mackworth-Prace & Grant (1957, 1962, 1970), Maclean (1993), Madge (1972), Marshall (1978), Mitchell (1992), Morel & Chappuis (1992), de Naurois (1994b), Penry (1994), Pickford *et al.* (1989), Pinto (1983), Porter, Christensen & Schiermacker-Hansen (1996), Rieker (1986), Ripley & Bond (1966), Short *et al.* (1990), Snow (1978), Steyn (1982, 1984, 1994b), Vernon (1991b), van der Weyden (1973), Zimmerman, D.A. *et al.* (1996).

23. Eurasian Scops-owl

Otus scops

French: Petit-duc scops **German:** Zwergohreule **Spanish:** Autillo Europeo
Other common names: European/Common Scops-owl

Taxonomy. *Strix Scops* Linnaeus, 1758, Italy. Probably forms superspecies with *O. brucei*, *O. senegalensis*, *O. sunia* and *O. flammeolus*. Formerly considered to include *O. mirus*, *O. longicornis*, *O. mindorensis*, *O. brucei*, *O. senegalensis*, *O. sunia*, *O. mantananensis*, *O. elegans*, *O. umbra*, *O. enganensis* and even *O. hartlaubii*, all now shown to be separated specifically by voice and, in some cases by DNA. Six subspecies recognized.

Subspecies and Distribution.

O. s. scops (Linnaeus, 1758) - France, Italy and C Mediterranean islands E to Volga R, S to N Greece, N Turkey and Transcaucasia; intergrades with *pulchellus*.
O. s. pulchellus (Pallas, 1771) - Volga R E to L Baikal, S to Altai and Tien Shan.
O. s. mallorcae von Jordans, 1923 - Iberia, Balearic Is, NW Africa (NC Morocco to Tunisia).
O. s. cycladum (Tschusi, 1904) - S Greece and S Asia Minor, S to C Israel and Jordan.
O. s. cypricus (Madarász, 1901) - Cyprus.
O. s. turanicus (Loudon, 1905) - Iraq and Iran (and perhaps this race SE Turkey) E to NW Pakistan.

Descriptive notes. 16-20 cm; wingspan 53-64 cm; 60-135 g. Occurs in grey-brown and rufous-brown morphs, latter less frequent. Facial disc grey, darker grey-brown around eyes; with thin whitish eyebrows; crown, small ear-tufts and upperparts brown-grey to rufous-brown with blackish-brown streaks, bars and vermiculations, nape with pale spots, mantle sides more rufous; line of black-tipped white or pale buff spots along scapulars; outer primaries broadly barred buff-white, tail more

narrowly barred; underparts lighter brown to buffish-white with black-brown streaks, thin bars and vermiculations, streaks widest on flanks; iris yellow; bill blue-black; legs noticeably thin, feathered buff-white; feet grey. At close range, differs from *O. brucei* in generally darker and more heavily marked appearance, pale nape spots, dark cross-bars below and presence of pale horizontal panels on belly; at distance confusable with *Athene noctua*, but has more upright stance, longer silhouette, lacks obvious pale spots above, is less boldly streaked below. Juvenile with less conspicuous streaks and vermiculations, especially on

underparts. Races vary in ground colour of plumage and in strength of dark markings: *pulchellus* mostly somewhat paler than nominate, with slightly narrower markings, and pale nape spots larger and more extensive; *malloreae* smaller, markings heavier; *cycladum* with darker and coarser markings; *cyprius* darkest race, dark grey-brown, with markings dark and coarse, white spots more distinct; *iranicus* pale silvery-grey, with dark shaft streaks narrow and sharply defined. Voice. Male territorial call a low, short whistle, "tyeu", repeated at intervals of 2-3 seconds for long periods; female higher-pitched; frequent duets during courtship.

Habitat. Breeds in rather open and semi-open broadleaved woodland, including parks, orchards and plantations, also cultivation with groves, and large gardens, riverine forest, roadside trees, and trees in quiet squares in small towns; locally, e.g. in Russia, mixed and open coniferous forest, and juniper (*Juniperus*) woodland; in Pakistan, juniper scrub and holly oak (*Quercus ilex*) in dry, rocky country; in general, requires good cover of trees, with suitable sites for roosting and nesting, and adjacent open ground with plenty of large insect prey; avoids closed forest and extensive open areas. In African winter quarters, prefers wooded savanna and tall grass with dense bushes, bushy country, acacias in dry river beds; in Senegal, found in dense bamboo. Breeds from sea-level to c. 2000 m; in Pakistan, locally to 3000 m.

Food and Feeding. Mostly insects and other invertebrates; also earthworms, spiders, and some small birds, reptiles, amphibians and mammals. Insects mostly crickets and grasshoppers (Orthoptera), beetles and moths; other prey include crustaceans (amphipods, isopods), tree frogs (*Hyla*), birds to size of Redwing (*Turdus iliacus*), and mice; bats and shrews taken occasionally. In S Spain, 159 items comprised 94.3% invertebrates, 2.5% reptiles, 1.2% amphibians, 1.2% mice and 0.6% birds. Hunts from perch, flying down to grab prey with feet, or may initially land alongside; also hunts on foot, seizing small prey with bill; pulls earthworms from ground with bill; moths caught in feet after fast aerial pursuit. Small insects swallowed whole; larger ones, and vertebrates, pulled apart; birds plucked. Nocturnal, occasionally diurnal.

Breeding. Season Mar-Aug in S Europe; lays May-Jun in N Africa. Monogamous, occasionally polygynous. Solitary; few records of pairs nesting in loose groups. Nest in tree cavity, hole in building or wall, or occasionally old nest of other species, especially Magpie (*Pica pica*) or raptor, sometimes disused burrow of bee-eater (*Merops*); readily accepts nestboxes; same site sometimes used for several years, though not known if by same pair; in 2 successive years, pair used sites 350 m apart. 2-6 eggs, normally 3-4; replacement clutch laid if first lost; laying interval 1-3 days; incubation generally 24-25 (20-31) days, by female, from second, third or last egg; hatching asynchronous, 4-5 young over 3 days; chick with white to pale grey down; female performs almost all brooding; young leave nest at 21-29 days, able to fly well by 30-33 days, cared for by parents for c. 5 weeks. Age of first breeding in wild unknown, probably 1 year. Oldest ringed bird 6 years.

Movements. Mostly migratory; S populations either partially so or resident. Wholly resident in Cyprus; *malloreae* present all year in Balearics and S & E Spain, although winter numbers considerably reduced, emigrants presumably making short-distance migrations to Africa, where several trapped in N during passage periods; *cycladum* largely migratory, some birds winter in S Italy and S Greece; Pakistan breeders winter largely in S Pakistan, some probably in W India. Remaining populations apparently all long-distance migrants, leaving breeding grounds from Aug onwards; most reach Afrotropical savanna regions in winter; return migration from late Mar. Overshooting migrants in spring occasionally reach N & NW Europe. Family may stay together during migration.

Status and Conservation. Not globally threatened. CITES II. In mid 1990's, European population estimated at 77,000-96,000 pairs, plus possibly 50,000 pairs in European Russia and 30,000 pairs in Turkey; main strongholds in Spain and Croatia, with c. 32,000 and 21,000, respectively; numbers generally stable or decreased; decline of over 50% in Austria, Switzerland and Ukraine; some increase in Hungary. Considered not rare in suitable habitat in Russia; in Lebanon, abundant in Bekaa valley (1974); marked population decrease in Israel due to pesticide use, but some recovery since 1970's; common in Cyprus. Marked range contraction in Europe in 20th century probably due to habitat changes and reduction in insect populations; in France, contracted towards S, since 1936 extinct in several areas in N half of country and only accidental in others, possibly related to decrease in populations of large insects due to widespread large-scale farming, or reduction in number of hollow trees; extinct in many former breeding areas in Switzerland, where habitat fragmented by spread of viticulture and agricultural intensification; similar history in Austria, where decreased from c. 50-150 pairs in 1983 to 20-30 in mid 1990's.

Bibliography. Ali & Ripley (1981), Arlettaz (1987, 1988, 1989, 1990a), Arlettaz & Fournier (1991, 1993), Bavoux & Burneleu (1985, 1991), Bavoux, Burneleu, Juillard & Nicolau (1993), Bavoux, Burneleu & Nicolau (1991), Beaman & Madge (1998), Colston & Curry-Lindahl (1986), Cottier & Maumary (1993), Cramp (1985), Danko & Paenovsky (1995), Díaz, Asensio & Tellería (1996), Dowsett & Dowsett-Lemaire (1993), Échécopar & Hùe (1964, 1978), Evans (1994), Fajardo & Babiloni (1996a, 1996b), Flint *et al.* (1984), Friedmann (1930), Friedmann & Keith (1968), Fry *et al.* (1988), Galeotti & Garibaldi (1994), Galeotti, Sacchi & Perani (1997), Gatter (1997), Goodman *et al.* (1989), Gorman (1995), Gragera (1996), Grimmett *et al.* (1998), Hagemeijer & Blair (1997), Handrinos & Akriotis (1997), Heller & Heller (1979, 1984), Henninger & Benderet (1990), Hùe & Échécopar (1970), Kämpfer-Lauenstein *et al.* (1993), Kemp & Kemp (1998), Kempf (1972), König (1973), Kumerloewe (1962), Landmann (1978), Le Gassic (1993), Ledant *et al.* (1981), MacKrell (1986), MacKworth-Pried & Grant (1957, 1970), Máñez (1994a), Marshall (1978), Martínez, J.A., Izquierdo *et al.* (1996), Meier-Zwicky (1993), Mendelssohn (1996), Mikkola (1983), Murray & Chappuis (1992), Mukherjee (1995), Paz (1987), Porter, Christensen & Schiermacker-Hansen (1996), Porro (1997), Ripley (1982), Roberts (1991), Roberts & King (1986), Rogacheva (1992), Rogier (1971), Rutgers & Norris (1972), Samwald & Samwald (1992), Shirihai (1993, 1996), Simeonov *et al.* (1990), Snow & Perrins (1998), Sorace (1991), Stepanyan (1990, 1995), Strel & Kalotas (1987, 1991), Vidal *et al.* (1984), Voous (1984, 1988), van der Weyden (1973, 1975), Zhao Zhengjie (1995), Zimmermann, D.A. *et al.* (1996).

24. Oriental Scops-owl

Otus sunia

French: Petit-due d'Orient **German:** Orient-Zwergohreule **Spanish:** Autillo Oriental
Other common names: Asian/Indian(?) Little/Eastern Scops-owl, East Asian Screech-owl

Taxonomy. *Scops sunia*, Hodgson, 1836, Nepal.

Probably forms superspecies with *O. brucei*, *O. senegalensis*, *O. scops* and *O. flammeolus*. Sometimes treated as conspecific with *O. scops*, and has been considered conspecific both with *O. senegalensis* and with *O. brucei*, or to include *O. mirus*, *O. mindorensis*, *O. mantananensis*, *O. elegans*, *O. umbra* and *O. enganensis* as races; all now shown to be specifically distinct on basis mainly of vocalizations. Proposed races *nicobaricus* and *distans* (Thailand) synonymous with *modestus*, although *nicobaricus* may prove to be a valid taxon; according to some, even *modestus* itself is possibly inseparable from *malayanus*. Original specimen of *O. alius* initially assigned to race *nicobaricus* (= *modestus*) of present species. Seven subspecies recognized.

Subspecies and Distribution.

O. s. sunia (Hodgson, 1836) - N Pakistan E to Bangladesh, and N India.

O. s. rufipennis (Sharpe, 1875) - S India.

O. s. leggei Ticehurst, 1923 - Sri Lanka.

O. s. modestus (Walden, 1874) - Assam (S to Brahmaputra R), Myanmar, N & W Thailand, Indochina; also Andamans and C Nicobars (Camorta).

O. s. malayanus (Hay, 1847) - S China (Yunnan E to Guangdong).

O. s. stictonotus (Sharpe, 1875) - SE Siberia, Sakhalin, NE China, N Korea.

O. s. japonicus Temminck & Schlegel, 1844 - Japan.

Descriptive notes. 18-21 cm; wingspan 50.5-52.6 cm; 75-95 g. Occurs in grey-brown and rufous morphs. Grey-brown morph similar to corresponding plumage of *O. scops*, differing mainly in less patterned upperparts and stronger black streaking below, but variable; rufous morph plain rufous above, apart from white scapular line and finely dark-streaked forehead and crown, and lighter below, breast with dark shaft streaks and thin horizontal pencil-lines; eyes yellow; bill horn-green or horn-yellow, tipped blackish; feet yellowish-grey or greyish-flesh colour. Differs from *O. bakka-moena* in lack of prominent nuchal collar. Ju-

venile as adult but with faint barring. Races *stictonotus* and *japonicus* larger and paler than nominate; *malayanus* and *rufipennis* dark; *leggei* darkest and smallest. Voice. Utters 3 "toik" calls in rhythmic phase, repeated at regular short intervals; in Thailand and Sri Lanka 4-note "toik" reported, with rhythm resembling that of "Here comes the bride".

Habitat. Prefers deciduous and mixed forest but not uncommon in open evergreen forest, and found also in riparian woodland, orchards and parkland; in Indian Subcontinent also groves in and around settlements and cultivation, and said to occur around city street lights in Sri Lanka; in Japan seems to prefer taller trees, and often found around temples; also gardens in winter in S. Mainly lowlands and foothills, to 1500 m, but up to 2300 in Himalayas.

Food and Feeding. Primarily insects and spiders; also small rodents and small birds. Prefers to feed along edges, in open, park-like woods, or in glades; forages both from the forest floor and in the canopy. Hunts from perch, dropping down on to prey, but frequently also in flight.

Breeding. Lays mid Feb-Apr/May in India and Pakistan, Apr-Jun in Siberia and China, May-Jun in Japan. Nest a hollow in a tree trunk, a nestbox, or a hole in a wall, at very variable height above ground. 3-6 eggs, usually 3-4; incubation 24-25 days; chick with whitish down.

Movements. N populations largely migratory, S ones resident. Birds from Siberia to N China and Japan winter mostly from S China to Thailand and S to Malaysia, and Sumatra (2 records, Jan and Mar); in Japan present mostly May-Sept/Oct, with very few noted in C & S parts in winter; some short-distance movements recorded in Himalayan region.

Status and Conservation. Not globally threatened. CITES II. Varies in abundance regionally; scarce and very local in Pakistan, and scarce but more widespread in Sri Lanka, but fairly common in most of Indian Subcontinent; uncommon in Thailand; uncommon in Japan, but said to be commonest strigid in SE Siberia.

Bibliography. Ali & Ripley (1981), Armstrong (1983), Beaman (1994), Brazil (1991), Brazil & Yamamoto (1989a), Deignan (1945), Flint *et al.* (1984), Grimmett *et al.* (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Knystautas (1993), Lekagul & Round (1991), van Marle & Voous (1988), Marshall (1978), Medway & Wells (1976), Phillips (1978), Phillips & Henry (1933), Riley (1938), Ripley (1982), Roberts (1991), Roberts & King (1986), Sankaran (1998), Smythies (1986), Sora *et al.* (1996), Stepanyan (1990, 1995), Tikader (1984), Voous (1988), Wells (1999).

25. Flammulated Owl

Otus flammeolus

French: Petit-due nain **German:** Ponderosaeule **Spanish:** Autillo Flamulado
Other common names: Flammulated Screech-owl

Taxonomy. *Scops (Megascops) flammeola* Kaup, 1853, Mexico.

Only New World species belonging to the Old World *Otus* assemblage referred to as subgenus *Otus*; differs from other New World *Otus* (subgenus *Megascops*) in lacking typical trilled song. Probably forms superspecies with *O. brucei*, *O. senegalensis*, *O. scops* and *O. sunia*. Longer-winged population in N part of range sometimes separated as *idahoensis* and darker birds from Guatemalan highlands described as *rufus*, but individual plumage variation appears to be continuous and biometric differences possibly clinal; also, other races described from S Mexico and Guatemala (*meridionalis*), Colorado (*frontalis*) and C British Columbia to NE California (*borealis*); type locality of species, however, apparently unknown, making objective use of subspecific names problematic. Treated as monotypic.

Distribution. Breeds from SW Canada (SC British Columbia) S to NW & SW USA and NE, W & C Mexico (and E in highlands to S Puebla, and NE Oaxaca). Winters to C & S Mexico and Guatemala, possibly El Salvador.

Descriptive notes. 15-17 cm; 45-63 g. Occurs in grey-brown and rufous morphs, with many intermediates and much individual variation; generally greyer in N and more rufous in S, with short, flattened ear-tufts. Facial disc pale greyish, with variable rufous wash strongest around eyes, faint darker concentric rings, and short white eyebrows; disc bounded by black-spotted dark rufous to solid black, and edged with buff; rest of plumage with black shaft streaks, cross-lines, and varying degree of rufous wash, scapulars with rufous-tinged creamy spots forming bold stripe; flight-feathers and tail with lighter bands; belly whitish with dark streaks and vermiculations; iris dark brown; bill grey-brown; tarsi densely feathered grey-brown to base of toes. Distinguished from other American *Otus* by size and short ear-tufts. Juvenile barred grey on white to pale greyish ground colour, but without longitudinal streaks of subsequent plumages. Voice. Rather deep, hollow, short "hoop", singly or repeated at intervals of 2-3 seconds; also double "hoo-hoop" notes in excitement.

Habitat. Primarily open coniferous forest in mountains, especially ponderosa pine (*Pinus ponderosa*) forest, or similar habitat, e.g. dry montane conifer forest mixed with aspen (*Populus*) or oak (*Quercus*), generally with brushy understorey. Nests in or near open conifer forest with large old trees, scattered thickets of saplings and/or shrubs, and clearings; in British Columbia, avoids pure ponderosa pine forest, opting for dry interior Douglas fir stands with open aspect, including selectively logged areas. Common features of habitat N of Mexico include cool, semi-arid climate, high abundance of nocturnal arthropod prey and some

dense foliage (preferred roosting habitat); in W North America restricted to mid-elevation montane zone, not extending to coastal pine belt or easternmost yellow pines; upper elevational limit perhaps set by low nocturnal temperatures, lower by high daytime temperatures or humidity. In Mexico, found at 1500–3000 m.

Food and Feeding. Almost entirely nocturnal insects, especially owl moths (Noctuidae), beetles, and crickets and grasshoppers; in observation in Colorado, owl moths appeared to be only food available during cold spring nights. Also spiders, and some small mammals, e.g. a shrew (*Sorex*) removed from stomach of apparently healthy owl that struck window; perhaps also a few small birds. In Colorado study, forest edge the most preferred foraging area. Frequently changes perch; locates prey from perch visually, apparently by moving head vertically and horizontally, then captures it from foliage of canopy, gleams from needles or branches while hovering, or picks up prey from ground; often pursues moths in air, seizing them with bill, and returns to same or different perch. Captive fledglings used feet to capture prey, including moths taken in upside-down position from ceiling. Nocturnal, with crepuscular foraging peaks during breeding.

Breeding. Season May–Aug. Monogamous, but extra-pair copulations occur; no divorce in 5 cases when both members of pair returned in subsequent year; when mates failed to return, females tended to move to adjacent territory and pair with widowed male; widowed males do not move. Solitary, but sometimes several pairs in close proximity to one another, territories possibly overlapping. Nest in natural cavity, old woodpecker hole, or nestbox. 2–4 eggs; replacement clutches rare; incubation 21–24 days, by female, fed at nest by male but still loses weight; chicks hatch with eyes closed, covered with white down; fledging c. 25 days; fledglings remain within 100 m of nest for 1 week after fledging, fed every 1–5 minutes by parents, then move away, passing through adjacent home ranges; in second week attempt to glean insects and follow adults on feeding trips, but sporadic feeding by parents continues; independent after c. 5 weeks. Fledging rates in successful nests 83% in New Mexico and 100% in Colorado, with total nest failure rate 18% and 13%, respectively, yielding probability of fledging 0.67 and 0.74; production per nest 1.5 for New Mexico and 2.3 for Colorado, and mean of 2.7 fledglings for 9 successful nests in Oregon. Age at first breeding unknown. Maximum recorded age in wild 8 years 1 month; lifespan probably much longer.

Movements. Still poorly understood. Altitudinal and translatitudinal migration hypothesized for N populations S to N Mexico, and very probable that many N birds winter in area from C Mexico to Guatemala, or extending to El Salvador (several winter records); S Mexican populations more likely resident. High breeding-site fidelity and variation of diet with prey abundance make nomadic behaviour unlikely. Vagrants recorded in USA E to Florida.

Status and Conservation. Not globally threatened. CITES II. Common in North America, but considered sensitive in USA and vulnerable in Canada; in Mexico fairly common to common, but local. Greatest intrinsic source of danger may be low reproductive rate. Potential threats include pesticides, pollution, and habitat change or destruction. Forest change and insecticide use could influence insect populations on which species depends; most visible impact is loss of nest cavities, and healthy woodpecker populations therefore important; occasionally uses nestboxes, although may be sensitive to type and/or placement, and further study needed. If requirement for old-growth timber verified, intensive management could be needed; silviculture not necessarily incompatible, as some aspects (controlled burning, thinning) tend to open up forest, but availability of nest-sites, roost-sites and adequate foraging areas important.

26. Moluccan Scops-owl

Otus magicus

French: Petit-duc mystérieux **German:** Molukken-Zwergohreule **Spanish:** Autillo Moluqueño
Other common names: Mysterious/Insular Scops-owl

Taxonomy. *Strix magica* S. Müller, 1841, Ambon (South Moluccas).

Probably forms superspecies with *O. mantananensis*, the two being closely allied to the *O. manadensis* superspecies. Sometimes considered conspecific with *O. manadensis*, or variously to include *O. beccarii*, *O. enganensis* and *O. insularis* as races, but all shown to be morphologically and/or vocally distinct; moreover, *O. alfredi* recently treated as a rufous morph of race *albiventris* of present species, but shown by morphological study to be distinct and separate species. Classification and true affinities of *Otus* taxa in SE Asia, particularly island forms, highly complex and still debatable, and relationship between present species and *O. manadensis* confused: forms *siaensis*, *mendeni*, *kalidupae* and *sulaensis* currently included in latter, but some or all sometimes placed with present species; current arrangement highly tentative, and further research required. Also, described races *leucospilus* and *obira* have been thought possibly synonyms of nominate race of present species, though at least the former distinct enough. Seven subspecies currently recognized.

Subspecies and Distribution

O. m. morotensis (Sharpe, 1875) - Morotai, Ternate.
O. m. leucospilus (G. R. Gray, 1860) - Halmahera, Kasiruta, Bacan.
O. m. obira Jany, 1955 - Obi Is.

O. m. magicus (S. Müller, 1841) - Seram, Ambon.
O. m. bouruensis (Sharpe, 1875) - Buru.
O. m. albiventris (Sharpe, 1875) - Lombok, Sumbawa, Flores, Lombok.
O. m. tempestatis (Hartert, 1904) - Wetar.

Descriptive notes. c. 25 cm; 114–165 g. Occurs in grey-brown, rufous and yellow-brown morphs, with various intermediates. Facial disc whitish with variable rufous to greyish tinge, and short white eyebrows; crown dark-streaked, ear-tufts barred; upperparts variably streaked and barred dark, bars sometimes strong, and scapulars with dark-tipped white spots which can be indistinct; flight-feathers prominently barred whitish, tail with thinner pale bars; underparts much paler than upperparts, usually coarsely streaked and with broken thin cross-lines; iris yellow; bill light yellowish-grey; distal 7–9 mm of tarsus

unfeathered, yellowish to greyish. All races of present species differ from *O. manadensis* mainly in more heavily barred tertials and uppertail. Juvenile has barred rather than streaked crown. Races variable, differ in size and general plumage coloration: *bouruensis* rather uniform buffy-brown above and white below; *tempestatis* and *albiventris* small, former with nearly fully feathered tarsus, latter with whiter and much less patterned lower underparts. **Voice.** Male territorial call a harsh, barking, raven-like croak, repeated at intervals of a few seconds, sometimes even harsher and more rapidly repeated; female slightly higher-pitched.

Habitat. Observed primarily in forested areas, and often in coastal swamp-forest; also secondary growth, well-forested limestone cliffs, locally large trees in settlements, palm plantations. Lowland and coastal areas, commonly up to 900 m, locally to 1500 m.

Food and Feeding. Insects; probably a few small vertebrates taken on occasion.

Breeding. Nestlings noted in Nov and Dec; nest probably in tree cavity; no other information.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Considered common on Buru and uncommon on Sumbawa; no data on status from rest of range. Occurs in Manusela National Park, Seram, and Kali Batu Putih, Halmahera. Forest destruction probably a threat in the long term.

Bibliography. Andrew (1992), van Bemmel (1948), Bowler & Taylor (1989), Coates & Bishop (1997), Indrawan *et al.* (1997), Inskipp *et al.* (1996), Isherwood *et al.* (1997), Johnstone *et al.* (1996), Marshall (1978), Ripley (1959), Siebers (1930), White & Bruce (1986).

27. Mantanani Scops-owl

Otus mantananensis

French: Petit-duc de Mantanani **German:** Philippinen-Zwergohreule **Spanish:** Autillo de la Mantanani
Other common names: South Philippines Scops-owl

Taxonomy. *Scops mantananensis* Sharpe, 1892, Mantanani Island.

Probably forms superspecies with *O. magicus*, the two being closely allied to the *O. manadensis* superspecies. Previously treated as conspecific with *O. scopis* or *O. sunia*, but vocally distinct from both. Island population off N Luzon (*calayensis*), included with *O. elegans*, sometimes placed with present species. Sulu form *sibutuensis* has been considered race of *O. manadensis*. Tumindao population (*steerei*) regarded as inseparable from *sibutuensis*. Racial allocation highly tentative, however, as no specimens known for many of islands listed. Four subspecies recognized.

Subspecies and Distribution.

O. m. romblonis McGregor, 1905 - Banton, Sibuyan, Romblon, Tablas, Tres Reyes and Semirara, in C Philippines.

O. m. cuyensis McGregor, 1904 - S Calamian Is (Dicabaito, Linapacan) and Cuyo I.

O. m. mantananensis (Sharpe, 1892) - Mantanani I, off N Borneo, and islands off S coast of Palawan.

O. m. sibutuensis (Sharpe, 1893) - Sibutu and Tumindao, in SW Sulu Is.

Descriptive notes. 18–20 cm; c. 100–110 g. Occurs in brownish and rufous morphs. Facial disc pale buffish with distinct thin dark border, and narrow whitish eyebrows; crown and short ear-tufts spotted dark, hindneck with black triangular spots; upperparts generally dark brown, mottled with black, with complex shaft streaks; outer webs of scapulars whitish; flight-feathers and tail barred pale; underparts much paler (perhaps even whitish) and peppered with black streaks and broken cross-lines, breast with variable rufous tinge; iris yellow; feet and bill grey; tarsus almost fully feathered. Juvenile of nominate race not described; *sibutuensis* whitish,

heavily barred dark brown, crown and breast plainer brown, more prominent barring on tertials and tail. Races differ in plumage tone, paler, more grey or more rufous: *romblonis* with general rufous tinge, nearly unbarred tertials and uppertail, heavily marked below; *sibutuensis* usually dull brown with irregular, subdued markings, reduced pale colour on scapulars; *cuyensis* large, with conspicuous black streaking. **Voice.** Male generally a deep, nasal, goose-like honk, repeated at intervals of c. 5–6 seconds; this often followed by 3–6 or more lower-pitched gruff notes, possibly from duetting female (though female *Otus* usually have slightly higher voice).

Habitat. Forest, woodland, coconut groves and casuarina trees; hunts at edges of wood, in clearings and among secondary growth. Lowlands and foothills.

Food and Feeding. Apparently mostly insects.

Breeding. Possibly lays Mar–May; nest in tree cavity; no other information.

Movement. Resident throughout range.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Sulu Archipelago EBA and Palawan EBA. Noted as common on Mantanani I in forest and coconut plantations; no data from elsewhere. Destruction of forest could be long-term threat, but some reports that species generally found away from tracts of undisturbed forest, and also near farmland areas, may indicate ability of at least some races to tolerate man-altered habitats.

28. Ryukyu Scops-owl

Otus elegans

French: Petit-duc élégant **German:** Schmuckeule **Spanish:** Autillo Elegante
Other common names: Elegant Scops-owl

Taxonomy. *Ephialtes elegans* Cassin, 1852, at sea off the coast of Japan. Probably forms superspecies with *O. manadensis* and *O. collari*. Formerly treated as conspecific with *O. sunia*, and until recently considered race of *O. scops*, but separated specifically on basis of vocal characteristics and morphology (comparatively larger feet); has recently been listed it as a race of *O. manadensis*, perhaps erroneously. Batan population sometimes separated as race *batanensis*; *interpositus* merged with nominate by some authors. S race *calayensis* placed with *O. mantanensis* by some, but seems closer to present species, at least on vocal and geographical grounds. Four subspecies recognized.

Subspecies and Distribution.

O. e. elegans (Cassin, 1852) - throughout Ryukyu Is (Nansei Shoto), S Japan.
O. e. interpositus Kuroda, 1923 - Daito Is (Minami-daito-jima).
O. e. botelensis Kuroda, 1928 - Lanyu I, off SE Taiwan.
O. e. calayensis McGregor, 1904 - Batan Is, Sabtang and Calayan, off N Philippines.

Descriptive notes. c. 20 cm. Drab brown or dark reddish-brown above, pale below, with fine and intricate black patterning, and pointed wing; silvery-grey facial disc with partial dark rim, latter bordered rufous. Resembles *O. sunia*; differs in larger size, no bright rufous morph. Juvenile buffy with fine dark barring. Races poorly differentiated: *botelensis* darker and even more finely marked than Japanese birds, often occurs in dark rufescent morph; *calayensis* generally with more rufous-buff tinge, scapular spots with ochraceous colour. Voice. Male call a hoarse, cough-like noise, "uhu" or "kuru" or "u-kuruk", lower-pitched

than *O. sunia*, repeated 15-30 times per minute; female call sounds more like "nye".

Habitat. Subtropical dense evergreen forest; locally, in or near villages. From sea-level to 550 m, probably higher.

Food and Feeding. Primarily insects, including beetles, moths, crickets and grasshoppers; also spiders, and some small mammals and small birds.

Breeding. Lays Mar-Jul. Nest in tree hole, often old woodpecker cavity. Usually 2-3 eggs, but up to 5; incubation c. 30 days; young fledge at c. 1 month. Mean fledging success 0.6 young per nest.

Movements. Probably mainly resident; N populations possibly disperse S after breeding.

Status and Conservation. Not globally threatened. Restricted-range species: present in Nansei Shoto EBA. CITES II. Common in suitable habitat throughout Ryukyus, where numbers thought to be quite large; status of race *interpositus* unknown. Race *calayensis* fairly common in forest or forest edge on Batan, Calayan and Sabtang, but total range extremely small. Lanyu race *botelensis* was formerly listed as threatened, with estimated population in mid 1980's of c. 200 individuals; more recently, however, considered to number 1000 individuals, with population stable, and prospects for survival regarded as good so long as habitat protected. Studies showed that breeding may be unsuccessful in disturbed habitats, and that suburban owls may not live so long as rural ones.

Beaman (1994), Brazil (1991), Brazil & Yamamoto (1989a), Clark & Mikola (1989), Dickinson *et al.* (1991), Inskipp *et al.* (1996), Kabaya & Higuchi (1977), King (1978/79), Marshall (1978), Manuel & Gilliard (1952), McGregor (1909-1910), Severinghaus (1989, 1992), Stattersfield *et al.* (1998), Zhao Zhengjie (1995).

29. Sulawesi Scops-owl

Otus manadensis

French: Petit-duc de Manado **German:** Manadoeule **Spanish:** Autillo de Célebes
Other common names: Celebes Scops-owl

Taxonomy. *Scops manadensis* Quoy and Gaimard, 1830, Manado, Sulawesi.

Probably forms superspecies with *O. elegans* and *O. collari*. Formerly treated as conspecific with *O. magicus*; also sometimes as including *O. beccarii* as race. Recently listed as including *O. elegans* as race, perhaps in error. Has traditionally been considered to include birds from Sangihe I, recently described as *O. collari*. Sulu form *sibutuensis*, included with *O. mantanensis*, sometimes placed with present species. Classification and true affinities of *Otus* taxa in SE Asia, particularly island forms, highly complex, with relationship between present species and *O. magicus* not fully understood; taxonomic status of races treated under present species unclear, with some or all sometimes treated under *O. magicus*, and current arrangement tentative. In particular, *siaoensis*, with shorter wings and much shorter and more narrowly barred tail may well be specifically distinct; *sulaensis* morphologically closer to *O. magicus* and probably better placed with that species, or perhaps specifically distinct; *mendeni* and *kalidupa* little known. Pending further research, five subspecies recognized.

Subspecies and Distribution.

O. m. siaoensis (Schlegel, 1873) - Siau I, N of Sulawesi.
O. m. manadensis (Quoy & Gaimard, 1830) - Sulawesi.
O. m. mendeni Neumann, 1939 - Banggai Is (Peleng, perhaps also Labobo).
O. m. sulaensis (Hartert, 1898) - Sula Is (Taliabu, Seho, Mangole, Sanana).
O. m. kalidupa Hartert, 1903 - Tukangbesi Is (Kaledupa).

Descriptive notes. 19-23 cm; 83-93 g. Occurs in brown and rufous morphs, latter very scarce; plumage variable. Similar to *O. magicus*, but smaller than Moluccan forms of latter; differs from all races of that species in less barred tertials and tail. Juvenile as adult but more barred, especially on crown and mantle. Race *siaoensis* much smaller, with very small ear-tufts, much shorter and more narrowly barred wings and tail; *mendeni* small, tarsus half feathered at front and bare at rear, grey morph peppered above; *sulaensis* with bare lower tarsus; *kalidupa* with feathering extending on to tops of toes, pale grey-brown, more finely patterned. Voice. For nominate race, main territorial call a clear, upward-inflected, mournful "ploek", c. 0.4 seconds long, repeated at intervals of up to 6

seconds; also rapid "kik-kok-kok-kok", and "oek-oek-oek" alternating with rising whistled "oi-oi-oi". Race *sulaensis* said to be quite different; other races unknown.

Habitat. Humid forest and forest clearings and edge, in geographical areas with high mean annual temperatures and average annual rainfall. Lowlands and hills, up to c. 2500 m above sea level.

Food and Feeding. Probably mainly insects; little information available. Nocturnal.

Breeding. Almost no information; indication that breeding may begin just before start of monsoon season.

Movements. Resident in Sulawesi, and presumably elsewhere.

Status and Conservation. Not globally threatened. CITES II. Appears to be fairly common and widespread in Sulawesi, where occurs in Tangkoko Nature Reserve and in Dumoga-Bone and Lore Lindu National Parks; two recent searches for *siaoensis*, known only from the type specimen, unsuccessful, and forest on Siau almost gone; no data on other populations, but all are poorly known and unlikely to be common. Main threat probably forest destruction.

Bibliography. Andrew (1992), Catterall (1997), Coates & Bishop (1997), Coomans de Ruiter (1950), Coomans de Ruiter & Maurenbrecher (1948), Davidson & Stones (1993), Ekstron *et al.* (1998), Holmes & Phillips (1996), Indrawan *et al.* (1997), Marshall (1978), Rozendaal & Dekker (1989), Stresemann (1940), Wardill (1995), Watling (1983), White & Bruce (1986).

30. Sangihe Scops-owl

Otus collari

French: Petit-duc de Sangihe **German:** Sangiheule **Spanish:** Autillo de la Sangihe

Taxonomy. *Otus collari* Lambert and Rasmussen, 1998, Sangihe Island, Indonesia.

Probably forms superspecies with *O. elegans* and *O. manadensis*. Original specimens, collected in 1866 and 1867, thought to be same species as *O. manadensis*. Subsequent authors placed it very tentatively with *O. magicus*, though without critical examination of specimens, and more recently again with *O. manadensis*, still without real knowledge of vocalizations or morphology. Later, in 1996, photographs and taped vocalizations revealed some differences from both *O. manadensis* and *O. magicus*; despite strong similarities with some individuals of *O. manadensis*, sufficient and constant morphological and vocal differences support treatment as separate species. Monotypic.

Distribution. Sangihe I, N of Sulawesi.

Descriptive notes. c. 19.5 cm; male 76 g. Rather small, generally brownish scops-owl with moderate-length ear-tufts, relatively long tail and long, narrow wings; relatively small, weak toes and claws. Facial disc brownish-white with dark lores and short whitish eyebrows; upperparts drab brown with dark shaft streaks and conspicuous buff spots, scapulars with black-tipped whitish and buff spots; flight-feathers and tail barred dark brown and buff; underparts somewhat paler, with prominent black shaft streaks and fine vermiculations; tarsus almost fully feathered; iris yellow; bill horn-brown; toes pale grey or pale brown. Differs from all *O. manadensis* in considerably longer, narrower wings, slightly longer tail, and combination of drabber appearance, paler facial disc with shorter, less obvious eyebrows, more contrasting narrower dark crown streaks, more coarsely mottled upperparts, plainer wing-coverts, reduced barring below with pale areas smaller, weaker feet; smaller than *O. magicus*, differing from small races *albiventer* and *tempestatis* of latter in shorter eyebrows, lack of solid dark ear-covert patch, broader dark bands on tail. Juvenile undescribed. Voice. High-pitched, downslurred, fluty whistle, "kleeeer", c. 0.7-0.8 seconds long, repeated at intervals of 8-15 seconds; also faster version, c. 3 notes per second.

Habitat. Forest, mixed plantations, secondary growth; also agricultural areas with trees and bushes. From sea-level to at least 315 m.

Food and Feeding. No information.

Breeding. No information.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Appears fairly widespread within single-island range, with records from various localities throughout, but no data on numbers. Observations show that species readily tolerates man-altered habitats, occurring especially in mixed plantations, a habitat type which has for many decades been a major feature of the island's landscape. No obvious threats; in view of highly restricted range and lack of real knowledge of its ecology, however, species should perhaps be placed in category of Vulnerable.

Bibliography. Anon. (1999), Lambert & Rasmussen (1998), Riley (1997a, 1997b), Sangster (1999).

31. Biak Scops-owl

Otus beccarii

French: Petit-duc de Beccari **German:** Beccarieule **Spanish:** Autillo de Biak
Other common names: Beccari/Papuan Scops-owl

Taxonomy. *Scops beccarii* Salvadori, 1875, Misori.

Sometimes treated as conspecific with either *O. manadensis* or *O. magicus*; song similar to latter's, but significant differences from both in plumage. Monotypic.

Distribution. Biak I, off NW New Guinea (Irian Jaya).

Descriptive notes. c. 20 cm. Occurs in dark brown and dark rufous-brown forms; almost certainly morphs, but sometimes interpreted as sexual difference. Facial disc pale whitish-brown, edged darker,

with short white eyebrows; forecrown with few indistinct dark streaks; entire upperparts, including crown and ear-tufts, densely barred, bars on nape more distinct; scapulars with largely white outer webs, some black at tips; flight-feathers and tail barred; underparts vermiculated black and white on brownish ground, or deep rufous with less obvious vermiculations, undertail-coverts white with some broken rufous and black bars; tarsus feathered to toes; iris yellow; bill grey; feet yellowish. Distinguished from all other *Otus* by lack of streaking above and below. Juvenile not described. **VOICE.** Hoarse, corvid-like

croak, repeated in series; at close range, described as "a quite disagreeable rasp".

Habitat. Forest and forest edge; also heavily wooded areas, locally near villages.

Food and Feeding. Insects; possibly some small vertebrates.

Breeding. No information.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Very poorly known. A survey conducted in 1973 on Biak found only 1 pair of this species, in the only undisturbed forest left on the island. Conservation status probably overlooked owing to its having frequently been treated as race of more widespread and commoner *O. magicus*. In view of very small range and apparent diminution of habitat, this species should probably be considered at best Vulnerable.

Bibliography. Beehler *et al.* (1986), Clark & Mikkola (1989), Iredale (1956), King (1978/79), Marshall (1978), Mayr & Meyer de Schauensee (1939a), Rand & Gilliard (1967).

32. Seychelles Scops-owl

Otus insularis

French: Petit-duc scieur

German: Seychelleneule

Spanish: Autillo de Seychelles

Other common names: Bare-legged Scops-owl

Taxonomy. *Gymnoscops insularis* Tristram, 1880, Mahé Island, Seychelles.

Originally placed in monotypic genus *Gymnoscops* on basis of its unfeathered tarsi and feet, and vestigial ear-tufts. Formerly considered race of *O. rutilus*, but vocalizations totally dissimilar. Sometimes treated as race of *O. magicus*, this supported by voice comparisons, but long isolation from all forms of latter, as well as morphological differences, suggest better regarded as separate species. Monotypic.

Distribution. Mahé I, in Seychelles. Unconfirmed reports also from Praslin and Félicité.

Descriptive notes. c. 20 cm. Resembles yellowish-brown or rufous morph of *O. magicus*, but smaller, and with minute ear-tufts (even in alert posture); differs further in unfeathered tarsus, often more buffish coloration, more prominent rim to facial disc, more distinct large black spots on crown and nape. Juvenile similar to adult. **VOICE.** Deep saw-like croak, "waugh", repeated every 3-4 seconds, also series of knocking "tok tok tok" sounds, the two sometimes interspersed; sequence may last up to 20 minutes.

Habitat. Virtually all records from secondary forest on upper slopes and in valleys, at 250-600 m above sea-level, usually close to water

source; thought originally to have inhabited lowland forest and woodland as well, before these latter destroyed.

Food and Feeding. Insects, tree frogs and lizards probably most important prey; stomach contents included grasshoppers, beetles, lizards, and some vegetable matter. Strictly nocturnal.

Breeding. Data few and sparse, with much speculation. High-pitched whistle apparently given during copulation, heard frequently in Oct and Apr, and fledged young seen in Nov and Jun, suggesting twice yearly breeding cycle. No nest found, but favours boulder fields in forest and spends much time on ground; subterranean nesting suspected, perhaps cleft in rocks. Clutch size unknown; 2 adults observed with presumed fledgling, suggesting that clutch may be reduced to single egg.

Movements. Resident.

Status and Conservation. CRITICALLY ENDANGERED. CITES II. Restricted-range species; present in Granitic Seychelles EBA. Following its discovery in 1880, and despite a specimen collected in 1940, no others sighted for over half a century; declared extinct in 1958. Its rediscovery on Mahé in 1959 led to speculation that 20 birds may remain on the island; studies in mid 1970's confirmed presence of 12 pairs, extrapolation from which suggested total population of perhaps over 80 pairs, possibly twice that; in mid 1990's, preliminary estimate of 90-180 territories. Local inhabitants of Mahé commonly report calls, perhaps suggesting that species more numerous than thought. Earlier reports of possible presence on Praslin and nearby Félicité I unconfirmed. Major threats are habitat destruction for housing development and timber exploitation, with new logging techniques making more areas accessible, e.g. upper Grand Bios Valley (where species known to exist), and probably introduced predators such as cats and rats. Some conservation measures already taken; Mome Seychellois National Park includes much of highland forest in its range, but extension of its boundaries desirable. Monitoring by means of controlled tape-luring can be used to determine distribution and status; more complete understanding of species' ecology and biology, especially breeding habits, required before degree of threat can be assessed and conservation measures successfully implemented. Speculation that introduced Common Barn-owl (*Tyto alba*) may compete for food considered improbable.

Bibliography. Bullock (1990), Clark & Mikkola (1989), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Diamond & Feare (1980), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans (1977), Gaymer *et al.* (1969), Gerlach (1997), Greenway (1967), Keith (1980), Kemp & Kemp (1998), King (1978/79), Loustau-Lalanne (1962), Marshall (1978), Penny (1968, 1974), Rocamora & Skerrett (1999), Shuker (1993), Sinclair & Langrand (1998), Stattersfield *et al.* (1998), Watson (1979, 1980), Wilson (1981).

33. Simeulue Scops-owl

Otus umbra

French: Petit-duc de Simalur

German: Simalureule

Spanish: Autillo de la Simeulue

Other common names: Mentauf/Simalur/Simulu Scops-owl

Taxonomy. *Pisorhina umbra* Richmond, 1903, Simalur Island.

Probably forms superspecies with *O. enganensis* and *O. alius*. Previously considered race of either *O. scops* or *O. sunia*. Sometimes treated as conspecific with *O. enganensis*, but vocalizations apparently very different. Monotypic.

Distribution. Simeulue I, off NW Sumatra.

Descriptive notes. 16-18 cm; c. 90-100 g. Overall reddish-brown with shortish ear-tufts, rounded wing; facial disc paler, plain rufous; crown with few thin shaft streaks; upperparts finely vermiculated with black, scapulars with black-edged whitish outer webs; flight-feathers and tail barred; underparts slightly paler than upperparts, with whitish vermiculations and rufous barring with occasional black shaft streaks within; tarsus feathered almost to toes; iris yellow to greenish-yellow; bill and feet grey. Differs from *O. sunia* in paler bill, fewer shaft streaks, darker belly, smaller ear-tufts; from *O. enganensis* in smaller size, with

smaller feet and claws, less heavily feathered tarsi. Juvenile undescribed. **VOICE.** Male territorial call two steady notes followed by higher and rising note, "pook-pook-pupook", repeated at varying intervals; in duet, female higher-pitched, can occasionally sound like long whine.

Habitat. Forest edge and remnant forest on steep slopes, especially coastal forest; noted also in clove plantations.

Food and Feeding. Probably mostly insects.

Breeding. Recorded singing on clear nights in Mar; no other information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Reports of status differ; usually said to be rare or "possibly rare", but one source clearly states that it is not rare. Poorly studied, and no indication of population numbers. Restricted to single island, main threat presumably habitat destruction.

Bibliography. Andrew (1992), Holmes, D.A. (1994a), Inskipp *et al.* (1996), MacKinnon & Philipps (1993), van Marle & Voous (1988), Marshall (1978), Richmond (1903), Stattersfield *et al.* (1998).

34. Enggano Scops-owl

Otus enganensis

French: Petit-duc d'Enggano

German: Engganoeule

Spanish: Autillo de la Enggano

Taxonomy. *Otus umbra enganensis* Riley, 1927, Enggano Island.

Probably forms superspecies with *O. umbra* and *O. alius*. Sometimes considered conspecific with *O. magicus*. Formerly treated as race of *O. umbra*, *O. scops* or *O. sunia*; seems closest to *O. umbra*, but separated specifically on basis primarily of vocal characteristics. Monotypic.

Distribution. Enggano I, off SW Sumatra.

Descriptive notes. 16-20cm. Very similar to *O. umbra*; differs in slightly more distinct dark markings, especially on crown and wings, duller and darker upperparts, more marked whitish eyebrows, hint of pale nuchal collar, slightly larger size. Juvenile undescribed. **VOICE.** Apparently rather similar to that of *O. magicus* and said to differ from *O. umbra*, but descriptions lacking.

Habitat. Very poorly recorded; presumably similar to that of *O. umbra*, occupying forest edge and wooded areas.

Food and Feeding. Probably mainly insects; no information.

Breeding. No information.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Enggano EBA. Reports on status vary widely, ranging from very rare to quite common; several different individuals were seen during a short visit to the island in 1983; very poorly studied. So far, habitats on Enggano relatively undisturbed, but recent tentative proposals for agricultural investments indicate possible risk of drastic changes in habitat in future.

Bibliography. Andrew (1992), Holmes, D.A. (1994a), Inskipp *et al.* (1996), Junge (1938), MacKinnon & Philipps (1993), van Marle & Voous (1988), Stattersfield *et al.* (1998), Sujatnika *et al.* (1995).

35. Nicobar Scops-owl

Otus alius

French: Petit-duc de Nicobar

German: Nicobareule

Spanish: Autillo de Nicobar

Taxonomy. *Otus alius* Rasmussen, 1998, Campbell Bay, Great Nicobar.

Probably forms superspecies with *O. umbra* and *O. enganensis*. Original specimen collected in 1966 initially listed as race (*nicobaricus* = *modestus*) of *O. sunia*, though long wings unlike all forms of that species; second specimen collected in 1977, and the two suspected of belonging to an undescribed taxon, tentatively placed with an "expanded" *O. magicus*. Subsequently treated as race *nicobaricus* (= *modestus*) of *O. sunia*, or as a form of *O. magicus* without subspecific allocation, but in one case listed as "*Otus* sp.". Recent examination of both specimens, along with comparisons with all other *Otus* taxa of non-mainland SE Asia (N to Philippines), led to conclusion that they were sufficiently distinct in plumage and morphology to warrant recognition as separate species. Monotypic.

Distribution. Great Nicobar I, southernmost of Nicobar Is.

Descriptive notes. c. 19-20 cm. Warm brown scops-owl, finely but distinctly barred all over, unstreaked above and with greatly reduced streaking below; mid-length ear-tufts finely barred; facial disc paler, lightly barred at lower edge, with indistinct outer border; rounded white scapular spots tipped black; iris conjecturally yellow, but no definite information; bill mostly brownish, medium-sized; lowermost part of tarsus, and much of its rear edge, unfeathered; toes and claws relatively large. Differs from all other Asian taxa of *Otus* in combination of finely barred plumage, with streaking totally lacking above and almost so below, underside being heavily barred whitish.

cinnamon and dusky brown, and relatively large claws; distinguished from geographically closest *O. umbra* in larger size, less rufous-toned plumage, paler facial disc, barred ear-tufts, larger black tips to scapulars, and proportionately much bigger feet and claws. **VOICE.** Male unknown. Female said to have given protracted melancholic moan on rising scale, "ooo-m" or "ooün", 2-2.5 seconds long, repeated after 3-5 seconds, uttered continuously for over 30 minutes.

Habitat. Both specimens collected in coastal forest, near sea-level.

Food and Feeding. One noted to have eaten a spider and a beetle; stomach contents of other bird included a 10-cm gecko.

Breeding. Male specimen had greatly enlarged testes on 3rd Mar; female specimen approaching breeding condition on 2nd Apr. No other information.

Movements. No information. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Very poorly studied species, not yet listed in any threat category simply because only very recently described; known from only 2 specimens, both from same site (Campbell Bay) on comparatively small island; no other records. Species may possibly occur on nearby islands, e.g. Little Nicobar a few km to N, but these areas barely studied by ornithologists; not found on the few pre-1966 expeditions to Nicobars. Nothing known of its ecology or biology. Probably a rare species, which should be considered at very best Vulnerable and more likely Endangered.

Bibliography. Abdulali (1967, 1978), Ali & Ripley (1981), Rasmussen (1998b), Ripley (1982), Sangster (1998), Sankaran (1998).

36. Pemba Scops-owl

Otus pemaensis

French: Petit-duc de Pemba

German: Pembaeule

Spanish: Autillo de Pemba

Other common names: Russet Scops-owl

Taxonomy. *Otus pemaensis* Pakenham, 1937, Wete, Pemba.

Relationships unclear. Often treated as race of *O. rutilus*. Monotypic.

Distribution. Pemba I, off N Tanzania.

Descriptive notes. c. 16 cm. Small scops-owl with small ear-tufts. Occurs in rufous and brown morphs, with intermediates varying considerably in colour. All have pale scapular spots and light eyebrows of varying prominence, and barred primaries but unbarred tail; dark rufous individuals usually unmarked; light rufous birds with some streaks on crown, some vague broad barring below, and few fine streaks on flanks; brown morph fairly uniform rufous-brown, unbarred above, dusky streaks on crown, creamy facial disc, pale below with fine vermiculations and thinly streaked breast and flanks, lower abdomen with more rufous and

white barring; tarsal feathering heavy and barred, reaching toes; iris yellow; bill dull greenish to yellow-grey with black tip; toes grey. Differs from *O. rutilus* in smaller size, much more uniform plumage. Juvenile colour morph immediately evident; pale young vaguely barred cinnamon, much more prominently barred on crown and tail. **VOICE.** Monosyllabic "hu" given at irregular intervals, or in fast runs of 4-6 in 10 seconds; in duet, male lower-pitched than female; similar to *O. rutilus*, but different timbre, less regular intervals. Calls start at sunset and continue until darkness.

Habitat. Well-wooded areas with densely foliated trees, often in clove and mango plantations. Roosts in dense undergrowth, at times quite low down c. 2 m from ground, and rarely stirring by day; reported to sit so tightly as to allow itself to be picked up.

Food and Feeding. Mainly insects. Hunts from perch, dropping on to prey; also gleans from foliage or hawks insects in flight. Nocturnal.

Breeding. Male with active gonads collected Aug; may breed Aug-Oct. Nest probably in tree cavity; reports of nests in heaps of dead branches and leaves on ground considered highly improbable. Virtually nothing recorded.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Pemba EBA. Currently considered Near-threatened. Appears to be fairly common and widespread, especially in clove plantations, in its restricted range, but no indication of population levels. Biology fairly unknown, warrants further study. Natives of Pemba said to identify this species with witchcraft and once thought it to be viviparous; unknown how this reflects or influences its numerical status, but human persecution a distinct possibility.

Bibliography. Bennun & Njoroge (1996), Britton (1980), Brown (1977), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Kemp & Kemp (1998), Mackworth-Præd & Grant (1957), Pakenham (1939, 1979), Short *et al.* (1990), Snow (1978), Stattersfield *et al.* (1998), Zimmerman, D.A. *et al.* (1996).

37. Comoro Scops-owl

Otus pauliani

French: Petit-duc du Karthala

German: Komoreneule

Spanish: Autillo de las Comores

Other common names: Grand Comoro Scops-owl

Taxonomy. *Otus rutilus pauliani* Benson, 1960, La Convalence, 1700 m, Grand Comoro.

Probably forms superspecies with *O. capnodes*, *O. moheliensis* and *O. rutilus*. Often considered race of *O. rutilus*, but clear differences in vocalizations, morphology and habitat preferences indicate separate species. Monotypic.

Distribution. Mt Karthala on Grand Comoro (Njazidja), in Comoro Is.

Descriptive notes. 15-20 cm; male c. 70 g. Small, relatively uniform scops-owl, with very small ear-tufts rarely visible in the field. Occurs in light and dark morphs. Grey or brown facial disc speckled with white, with some darker rings, and faint pale eyebrows; upperparts dark grey-

brown or brown with indistinct paler barring, scapulars inconspicuously spotted buff; wings and tail barred; underparts light to dark rufous-brown, densely vermiculated darker, with sparse and variably distinct black shaft streaks; lower tarsus unfeathered; iris yellow or dark brown; bill grey-brown; legs and feet brownish. Distinguished from *O. rutilus* by smaller size, almost no ear-tufts, finely barred, unstreaked plumage, less extensively feathered tarsus, and very small bill. Juvenile unknown. **VOICE.** High whistled "toot" or "choo" at regular intervals of 1-2 seconds, quickly turning into faster series of shorter down-

slurred "cho" notes repeated at half-second intervals for 10 minutes; female also drawn-out "choeiet" in duet.

Habitat. Forest and forest edge on upland slopes, extending into adjoining tree-heath scrub; recorded at 1000-1800 m, but recently reported at lower levels.

Food and Feeding. Largely unknown, probably insects; 1 stomach contained beetle remains. Species' weak talons suggest that it normally takes invertebrates.

Breeding. Probably lays Sept-Dec; very vocal throughout year. Highly territorial, territory size c. 5 ha. Nest in cavity.

Movements. Probably sedentary.

Status and Conservation. CRITICALLY ENDANGERED. CITES II. Restricted-range species; present in Comoro Islands EBA. A minimum of c. 1000 pairs may exist within the estimated 100 km² of suitable habitat remaining on Mt Karthala. Population seems stable and perhaps not under such great threat as feared, but deforestation is slowly creeping up the mountainside. Strongholds in areas where terrain too rocky to be cleared for agriculture. Situation may worsen in the future, with local deforestation causing increased fragmentation of habitat, and further destruction from practice of burning to obtain grazing land for cattle; clearance and cattle grazing make conditions more favourable for the introduced Common Myna (*Acridotheres tristis*), which competes with present species for nest cavities. Proposal for a nature reserve on Mt Karthala should be implemented immediately.

Bibliography. Benson (1960), Clark & Mikkola (1989), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Herremans (1988), Herremans *et al.* (1991), Hornbuckle (1997), Kemp & Kemp (1998), Louette (1984, 1988a, 1992), Louette & Stevens (1992), Louette, Herremans *et al.* (1990), Louette, Stevens *et al.* (1988), Shuker (1993), Sinclair & Langrand (1998), Snow (1978), Stattersfield *et al.* (1998).

38. Anjouan Scops-owl

Otus capnodes

French: Petit-duc d'Anjouan

German: Anjouaneule

Spanish: Autillo de Anjouan

Other common names: Smoky Scops-owl

Taxonomy. *Scops capnodes* Gurney, 1889, Anjouan.

Probably forms superspecies with *O. pauliani*, *O. moheliensis* and *O. rutilus*. Sometimes treated as race of *O. rutilus*, but analysis of vocalizations and plumage characters indicates specific status appropriate. Monotypic.

Distribution. Anjouan (Ndzuani), in Comoro Is.

Descriptive notes. c. 22 cm; male 119 g. Smallish scops-owl with very small ear-tufts. Occurs in dark grey-brown and rufous-brown morphs. Rufous morph with head dusky brown with white spotting, facial disc creamy with whitish eyebrows, upperparts brown to rufous-brown with fine buffish bars and spots, flight-feathers barred, underparts paler with dark shaft streaks and finely vermiculated with sepia, buff and cream. Dark morph dark chocolate-brown to grey-brown, no white in plumage, finely grizzled as opposed to barred or streaked. Tarsus with distal third bare; iris greenish-yellow; bill horn-grey to grey-green;

feet yellowish-grey. Distinguished from *O. rutilus* by darker appearance, no pale scapular stripe, much less obvious ear-tufts, longer wings. Juvenile undescribed. **VOICE.** Prolonged whistle, "peeoeoe" or "peeoo", recalling Grey Plover (*Pluvialis squatarola*), repeated 3-5 times at intervals of 0.5-1.5 seconds; also long harsh screech; sometimes calls during day.

Habitat. Restricted to remnant primary forest on mountain slopes above 550 m, mostly above 800 m; no records from exotic plantations in foothills. Perches usually in dense vegetation, 3-15 m above ground; roosts in holes in large trees.

Food and Feeding. No definite information; probably insects.

Breeding. No confirmed data. Nest probably in cavity in thick tree trunk, e.g. where branch broken off; several records of bird seen perched at entrance of such sites.

Movements. No information; presumably sedentary, with only local movements.

Status and Conservation. CRITICALLY ENDANGERED. CITES II. Restricted-range species; present in Comoro Islands EBA. Speculation that over-collecting in late 1800's might have caused its extinction was unfounded, as the number of specimens collected was relatively small, and the species survives well so long as its habitat is available; its apparent "disappearance" was due largely to its being overlooked as a result of its vocalizations being very unlike those associated with owls, and it has always been well known to local people. Very local, but reasonably common on steep forested slopes; on basis of confirmed sightings and known habitat preferences, population estimated at possibly 100-200 pairs. Clearing of primary forest and replacement by exotic plantations presumed biggest threat; remaining suitable habitat scarce, totalling only c. 10-20 km². Species also hunted for food, rendering surviving population even more threatened. Speculated also that introduced rats may affect breeding success. No known conservation measures taken, and no protected areas on Anjouan. Urgent action recommended. Possibility of captive breeding recently suggested, but capturing of wild birds, which are prized as human food, in such a vulnerable habitat could cause further problems.

Bibliography. Anon. 39. Moheli Scops-owl

Otus moheliensis

French: Petit-duc de Mohéli **German:** Mohelieule **Spanish:** Autillo de Moheli

Taxonomy. *Otus moheliensis* Lafontaine and Moulart, 1998, Mohéli.

Very recently discovered species. Probably forms superspecies with *O. pauliani*, *O. capnodes* and *O. rutilus*. Monotypic.

Distribution. Mohéli (Mwali), in Comoro Is.

Descriptive notes. c. 22 cm, male 95 g, female 116 g. Fairly uniform-looking scops-owl with greatly reduced ear-tufts. Occurs in brown and rufous morphs. Brown morph rufescent-brown, spotted and barred blackish on crown and upperparts, especially on nape, with some blackish shaft streaks; scapulars with paler cinnamon outer webs; facial disc and underparts more rusty-cinnamon, breast with blackish shaft streaks, flanks and belly with fine darker bars. Rufous morph similar, but more rufous-cinnamon all over. Lower third of tarsus unfeathered; iris yellow; bill horn; lower tarsus and feet grey. Juvenile undescribed. Voice.

Poorly known; male said to give series of 1-5 hissing whistles; a screech also described.

Habitat. Dense humid forest on hillsides; also at lower densities in degraded forest; recorded at 450-790 m.

Food and Feeding. Probably insects.

Breeding. No information.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Appears at present to be common in forested uplands, with c. 1 bird/5 ha in undisturbed forest; in degraded parts, 1 bird/10 ha. Current population estimated at c. 400 individuals. Main problem is habitat loss; forest being gradually destroyed for agriculture, with no sign of clearance ceasing; in 1995 dense humid forest restricted to 1070 ha (or 5% of the island's surface area), while between 1955 and 1968 it was estimated at 5000-6000 ha (30%). Species not yet listed in any threat category simply because only recently discovered; should probably be placed in Endangered category.

Bibliography. Anon. (1998c, 1998g), Lafontaine & Moulart (1998, 1999), Moulart (1998).

40. Madagascar Scops-owl

Otus rutilus

French: Petit-duc malgache **German:** Madagaskar-Zwergohreule **Spanish:** Autillo Malgache
Other common names: Malagasy/Ruddy Scops-owl

Taxonomy. *Scops rutilus* Pucheran, 1849, Madagascar.

Probably forms superspecies with *O. pauliani*, *O. capnodes* and *O. moheliensis*. Has been considered to include first two, as well as *O. pambensis* and *O. insularis*, as races; vocal comparisons and morphology (size, plumage markings, extent of tarsal feathering) indicate that all are specifically distinct. Race *mayottensis* possibly sufficiently distinct to merit full species status; more study needed. Population in drier W Madagascar apparently an unrecognized taxon; further research in progress. Two subspecies currently recognized.

Subspecies and Distribution.

O. r. mayottensis Benson, 1960 - Mayotte I (Comoro Is).

O. r. rutilus (Pucheran, 1849) - Madagascar.

Descriptive notes. 22-24 cm; wingspan 53 cm; male 85-107 g, female c. 112 g. Occurs in grey, brown and rufous morphs, with many intermediates; extremely variable. Facial disc pale, darker around eyes, with off-white eyebrows; crown and upperparts grey-brown to brown, often tinged rufous, with buffish spots and black shaft streaks, scapulars with black-edged white spots; flight-feathers and tail barred; paler below, with bold blackish streaks and faint vermiculations, breast centre sometimes plain whitish, also abdomen. Rufous morph strongly tinged rufous all over, sometimes nearly lacking black markings. Tarsus feathered to toes; iris yellow; bill largely blackish; toes grey-brown. Juvenile similar to adult. Race *mayottensis* slightly larger, darker, with bigger ear-tufts, more prominently white chin and lores, less white on abdomen; birds in dry parts of W Madagascar average greyer and less boldly marked. Voice. Fast series of 5-15 short, even-pitched "hoo" or "broo" notes, increasing slightly in volume, last 2 notes softer, whole phrase lasting 1.5-5 seconds, repeated after some seconds; in dry areas of W, shorter, slower series of 3-7 more tremulous, lower-pitched notes, phrase 2-3 seconds; *mayottensis* similar to E Madagascar birds, but notes a bit longer and deeper, sequence slower.

Habitat. Variety of habitats, ranging from primary and secondary forest to thickets, humid bush country and urban parks, and not uncommon in trees around villages; avoids exotic plantations; in

W & SW Madagascar, also drier forest. Spends daytime concealed in thick foliage, sometimes low down. Sea-level to 2000 m. Recorded in lowland secondary forest on Mayotte.

Food and Feeding. Mostly insects, especially beetles and moths; possibly some small vertebrates. Strictly nocturnal.

Breeding. Lays Nov-Dec. Nest in tree cavity, occasionally in abandoned stick nest of other bird. 4-5 eggs; incubation and fledging periods unknown.

Status and Conservation. Not globally threatened. CITES II. Generally common and widespread in suitable habitat throughout range.

Reported as common to abundant e.g. in forested areas between Betsileo and Tanala, forest of Ankafana, and near Zahamena. Rare in woodlands of the high plateau near Ambositany, Antananarivo. Occurs in several protected areas, e.g. Ranomafana National Park, Perinet Special Reserve and Berenty Private Reserve.

Bibliography. Appert (1996), Benson *et al.* (1976-1977), Dee (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Goodman & Parrillo (1994), Goodman *et al.* (1997), Herremans (1988), Hornbuckle (1997), Kemp & Kemp (1998), Langrand (1995), Lewis (1998), Louette (1988c), Marshall (1978), Milon *et al.* (1973), Morris & Hawkins (1998), Ramanitra (1995), Rand (1936), Safford & Duckworth (1990), Sinclair & Langrand (1998), Snow (1978), Young (1995).

41. Sao Tome Scops-owl

Otus hartlaubi

French: Petit-duc de Sao Tomé **German:** Hartlaubeule **Spanish:** Autillo de Santo Tomé

Taxonomy. *Noctua Hartlaubi* Giebel, 1872, São Tomé Island.

Affinities uncertain. May be more closely related to *O. rutilus* than to any mainland African species, though song fairly similar to that of *O. senegalensis*; formerly suggested as race of *O. scops*, but differs significantly in morphology and voice. Monotypic.

Distribution. São Tomé I; report of possible presence on Príncipe.

Descriptive notes. 16-19 cm; c. 80 g. Small scops-owl with tiny ear-tufts. Facial disc light rufous-brown, with white chin and eyebrows; crown and upperparts warm rufous-brown with rufous vermiculations and blackish shaft streaks, scapulars with black-tipped white spots; flight-feathers mottled with buff and white, tail with narrow buff bars; underparts finely vermiculated with brown, rufous and white, and bold black streaking; tarsus unfeathered; iris and bill yellow. A grey-brown morph has been described, but apparently very rare. Juvenile paler, finely barred light brown above and below. Voice. High whistling trill,

"hu-hu-hu-...", rising slightly, higher-pitched and more mellow than that of *O. scops* or *O. senegalensis*, given at intervals of 15-20 seconds; also low, harsh "kwo". Heard by day, as well as at dusk and night.

Habitat. Densely foliated primary and secondary forest, and plantations, to 1300 m above sea-level; densities highest in secondary forest and clove and mango plantations at c. 400 m.

Food and Feeding. Stomach contents indicate insects, such as grasshoppers, beetles and moths; some small lizards also taken. Appears to be partly diurnal. Forages in lower parts of forest; hunts from perch 1.5-10 m above ground, dropping on to prey; also gleans from foliage or hawks prey in flight; occasionally descends to ground.

Breeding. Male with active gonads in Aug, fledglings observed in Oct; may breed before start of short rains during Aug-Oct. No other information.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in São Tomé EBA. Currently considered Near-threatened. Poorly known, and for some time thought to be rare, but on protracted visits to forest areas found to be common, e.g. in dense secondary vegetation bordering Io Grande R; distribution appears highly fragmented, but factors responsible for its absence from some parts unknown; seems able to accept some modification of habitat on edge of its range, and will recolonize areas abandoned after cultivation, but shuns shaded cocoa and coffee plantations. No figures available on population; competition from Common Barn-owls (*Tyto alba*) and predation by cats possibly reducing species' numbers; pesticides heavily used on São Tomé during 1963-1973, probably had adverse effect. Studies of species' biology and population level much needed.

42. Western Screech-owl

Otus kennicottii

French: Petit-duc des montagnes **German:** Westkreischeule **Spanish:** Autillo Californiano
Other common names: Kennicott's Screech-owl; Vinaceous Screech-owl (*vinaceus*)

Taxonomy. *Scops Kennicottii* Elliot, 1867, Sitka, Alaska.

Sometimes considered to form superspecies with *O. seductus*, *O. cooperi* and *O. asio*. Formerly treated as conspecific with *O. asio*, and may interbreed where ranges meet or overlap (separated by 60 km in Oklahoma "panhandle", slightly sympatric in Colorado Springs, broadly overlapping in Texas, areas of contact in Mexico undetermined); vocal and DNA analyses, however, show that better treated as separate species. Often considered to include *O. seductus* and *O. cooperi* as races. Race *vinaceus* has been proposed as a megasubspecies. Geographical limits of listed races uncertain, with intergrades at boundaries. Many additional races described, but some probably reflect individual variation only: *saturatus* included in nominate *kennicottii*; *macfarlanei* and *brewsteri* in *bendirei*; *mychophilus*, *inyoensis* and *cineraceus* in *aikeni*; *quercinus*, *clazus* and *gilmani* in *cardonensis*; *sortilegus* in *suttoni*; and *sinaloensis* in *vinaceus*. Eight subspecies recognized.

Subspecies and Distribution.

- O. k. kennicottii* (Elliot, 1867) - coast from S Alaska and NW Canada to NW California.
- O. k. bendirei* (Brewster, 1882) - E Washington and Montana S to SE California.
- O. k. aikeni* (Brewster, 1891) - from SW USA (California E to W Oklahoma) S to N Mexico (NC Sonora).
- O. k. cardonensis* Huey, 1926 - S California and N Baja California.
- O. k. xantusi* (Brewster, 1902) - S Baja California.
- O. k. yumanensis* A. H. Miller & L. Miller, 1951 - SE California and SW Arizona to N Mexico (NW Sonora).
- O. k. suttoni* R. T. Moore, 1944 - SW Texas S to Mexican Plateau.
- O. k. vinaceus* (Brewster, 1888) - Mexico (S Sonora and W Chihuahua to N Sinaloa).

Descriptive notes. 21-24 cm; male 131-210 g, female 157-250 g. Occurs in grey-brown and rufous-buff morphs; latter generally subdued cinnamon-buff, found in N of range, rare elsewhere. Facial disc predominantly whitish, with thin dark margin; neck region light tawny to white; upperparts with dark shaft streaks, more prominent on head than on back, and faint thin vermiculations; often purplish tint above, especially on wings; scapulars with black-edged whitish outer webs forming pale shoulder line; flight-feathers strongly barred; underparts lighter than upperparts, prominently streaked dark, with streaks crossed by much thinner bars

or spots, markings heavier on breast than on flanks; tarsus fully feathered; iris yellow; bill blackish; toes grey-brown. Distinguished from *O. asio* and *O. trichopsis* by darker bill, less coarse streaking below, and much bigger than *O. trichopsis*. Juvenile deep grey-brown above, indistinctly and rather broadly barred with dusky, dull white below, broadly barred greyish-dusky. Races differ in plumage colour, streaking and size, but highly variable, generally paler in more arid regions: *bendirei* longer-winged than nominate; *cardonensis* darkish, more densely marked; *suttoni* darkest; *vinaceus* somewhat smaller, paler with vinaceous wash, vermiculations below in form of reddish dots; *yumanensis* pale pinky-grey; *aikeni* palest grey; *xantusi* almost as pale, smallest. Voice. Primary song a double trill, first short and second long, dropping near end; secondary song accelerating series of c. 5-15 soft hoots, final notes run together, in bouncing-ball rhythm; female higher-pitched; duets last 2-4-5 seconds.

Habitat. Open woodland, semi-open country with scattered trees and bushes, riparian forest, cactus desert, also parks and larger gardens in suburban areas; some preference for pine-oak forest. In general, prefers open tree or cactus growth with abundance of insects and small mammals, available cavities, and environmental factors with which its plumage coloration blends well. In Oregon, found to inhabit riparian zones, abandoned homesteads, and some cliffs; in Idaho, riparian areas with abundant deciduous cover 4-8 m tall; often uses river-bottom and bunch-grass habitat, or may opt for mixture of coniferous and deciduous habitats; locally, occurs in stands of giant cardon and saguaro (*Carnegiea*) cacti in upland desert, in Joshua trees (*Yucca*), in stands of sycamore (*Acer*) and cottonwood (*Populus*), tamarisk (*Tamarix*) and willow (*Salix*) along rivers, in groves of mesquite (*Prosopis*), in open pinyon-juniper woodland or pine forest, and atypically in low, dense Douglas fir (*Pseudotsuga*) forest. Prefers to roost among denser trees, sometimes next to trunk; after leaf fall, will also roost in nestboxes or cavities.

Food and Feeding. Insects, small mammals (rodents, bats, flying squirrels) and birds; also, some frogs and reptiles. Opportunistic and catholic in diet. In studies in Oregon, invertebrates formed 79-8% of food, with remaining 20-2% vertebrates; beetles accounted for 21-4% of diet, while grasshoppers and crickets (*Stenopelmatus*) comprised 52%; rodents of family Cricetidae made up 40-2% of vertebrate prey; likely that flexibility in habitat choice provides species with a fairly wide prey base. In winter in C Utah, diet consisted of 24-9% mammals, 51-3% birds and 23-8% insects; House Sparrow (*Passer domesticus*) the major component of most pellets. In Idaho, size range of prey mostly 16-35 g. Observed to take smaller and larger mice in inverse proportion to their availability, perhaps because smaller, younger prey more vulnerable or pose less risk of injury, or because energy expended in catching and killing large prey not worth risking. Nocturnal; somewhat crepuscular, foraging within 45 minutes after sunset. A sit-and-wait hunter, dropping from perch on to prey; will pursue prey over short distances; often catches bats in flight; also observed foraging on ground for earthworms.

Breeding. From Feb/Mar, earlier in S. Nest in natural tree cavity or old woodpecker hole, e.g. of flicker (*Colaptes*), sometimes in nest of Black-billed Magpie (*Pica pica*), or in cavity in cliff; also in juniper along dry streambeds; in giant saguaro, at heights from 1-2 m above ground almost to top; also uses nestboxes, 3-7 eggs, usually 4-6, with slight trend towards reduced clutch size from interior towards Pacific coast; laying interval 1-2 days; incubation c. 26 days, by female; chick with whitish down, brooded and fed by female, later fed by both parents; young leave nest at c. 28 days of age, tended by parents for further 5-6 weeks before independent.

Movements. Most populations resident; partial migrant in N. Juveniles may disperse longer distances to find unoccupied territory; in SW Idaho in Jun-Aug, c. 58 days after fledging.

Status and Conservation. Not globally threatened. CITES II. Fairly common to locally common. In many areas, has suffered substantial habitat losses with development of riparian woodland; however, relatively abundant food has allowed species to become more numerous in city parks and suburban areas. In Washington, individual found drowned, suspended in river from monofilament fishing line.

Bibliography. 43. Balsas Screech-owl

Otus seductus

French: Petit-duc du Balsas **German:** Balsaskreischeule **Spanish:** Autillo del Balsas

Taxonomy. *Otus vinaceus seductus* R. T. Moore, 1941, Michoacan, Mexico.

Sometimes considered to form superspecies with *O. kennicottii*, *O. cooperi* and *O. asio*. Often treated as race of *O. asio* or *O. kennicottii*, but differs in eye colour and vocalizations. Birds from Colima sometimes separated as race *colimensis*. Monotypic.

Distribution. SW Mexico, from S Jalisco and Colima to W Guerrero.

Descriptive notes. 24-26 cm; c. 155-165 g. Similar to race *vinaceus* of *O. kennicottii*; differs in larger size, browner ground colour above (still with pinkish wash), brown eyes (reported rarely as golden-brown), greenish bill; toes with large bristles; no rufous morph. Voice. Like bouncing-ball song of *O. kennicottii* but gruffer, "hooh-hooh-huh-huh-huhuhurr", soon repeated; also rather harsh whinnying scream.

Habitat. Arid open to semi-open areas, deciduous woodland with giant cardon, mesquite, thorn forest, tall cactus and second growth. From c. 600 m to 1500 m.

Food and Feeding. Little known. Insects and small vertebrates have been recorded.

Breeding. Lays during Jun; nest and eggs undescribed.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Described as fairly common to common, but little information available on status and ecology. Has been recently recorded between Autlán and Ciudad Guzmán (Jalisco), and at La Cumbre (Colima), Cañón de Lobos (Morelos) and Sierra de Atoyac (Guerrero). Available habitat appears to be decreasing. Currently being considered as candidate for inclusion in Red Data Book.

Bibliography. Anon. (1998a), Howell & Webb (1995a), Morris & Buffa (1996), Stotz *et al.* (1996).

44. Pacific Screech-owl

Otus cooperi

French: Petit-duc de Cooper **German:** Mangroveeule **Spanish:** Autillo de Manglar
Other common names: Oaxaca Screech-owl (*lambi*)

Taxonomy. *Scops cooperi* Ridgway, 1878, Santa Ana, Costa Rica.

Sometimes considered to form superspecies with *O. kennicottii*, *O. seductus* and *O. asio*. Often treated as race of *O. asio* or *O. kennicottii*, but appears to be vocally distinct from both. Race *lambi* proposed as full species, but latest studies indicate that subspecific treatment more appropriate: *chiapiensis* poorly differentiated, possibly not tenable. Three subspecies recognized.

Subspecies and Distribution.

- O. c. lambi* R. T. Moore & Marshall, 1952 - S Mexico (Pacific slope of Oaxaca).
- O. c. chiapiensis* R. T. Moore, 1947 - SE Mexico (Chiapas).
- O. c. cooperi* (Ridgway, 1878) - extreme SE Mexico (S Chiapas) to NW Costa Rica (Guanacaste).

Descriptive notes. 20-25.5 cm; 145-170 g (*cooperi*), c. 125 g (*lambi*). Facial disc pale grey with faint dusky rings, bordered by white mixed with dark brown; shaft markings on head narrow, so that crown appears no darker than back; rather pale tawny-grey above, finely vermiculated with dusky and with black shaft streaks; whitish scapular spots forming pale line, wing-coverts variably edged whitish; flight-feathers barred; off-white below, vermiculated with dusky and brown, with very narrow long black shaft streaks; tarsus fully feathered, toes bristly; iris yellow; bill greenish or with creamy-yellow tip. Juvenile greyish-buff above, whitish

below with deep buff on breast, with fine dusky barring. Race *lambi* smaller, more prominently dark crown contrasting with "frosty" areas around hindneck and face. Voice. Primary (secondary?) song up to 15 short notes rapidly delivered in series which rises in pitch at middle, then drops again, sometimes with initial short trill, "u-pu-pu-pu-pu...", or "prrr pu-pu-PU-PU-pu-pu"; also single, low gruff "woof" or "whuh"; *lambi* said to have whinnying secondary song.

Habitat. Dry woodland, semi-open country with scattered trees and bushes, palms and giant cardon and cactus, second growth and lakeside fields; also swamp-forest and edges of mangroves. Sea-level to 1000 m.

Food and Feeding. Mostly large insects, such as beetles, katydids, moths; also scorpions, and almost certainly small vertebrates (e.g. rodents).

Breeding. In Oaxaca, nest with 2 young and 1 egg in Mar, juvenile seen in May; presumably breeds mainly in dry season, around Mar. Nest in tree cavity or old woodpecker hole. 3-5 eggs; family group remains together into early wet season.

Movements. Resident, but little known.

Status and Conservation. Not globally threatened. CITES II. Considered fairly common to common in most of range, but no information on population size. Occurs in a series of protected areas in Costa Rica, including Santa Rosa, Palo Verde and Barra Honda National Parks.

Bibliography. Anon. (1998a), Binford (1989), Cooper (1997), Howell & Webb (1995a), Monroe (1968), Ridgely & Gwynne (1989), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987).

45. Eastern Screech-owl

Otus asio

French: Petit-duc maculé

German: Ostkreischeule

Spanish: Autillo Yanqui

Other common names: Common Screech-owl

Taxonomy. *Strix Asio* Linnaeus, 1758, South Carolina.

Sometimes considered to form superspecies with *O. kennicottii*, *O. seductus* and *O. cooperi*. Formerly treated as conspecific with *O. kennicottii*, and may interbreed in areas of range overlap (separated by 60 km in Oklahoma "panhandle", slightly sympatric in Colorado Springs, broadly overlapping in Texas, undetermined in Mexico), but vocal and DNA analyses indicate that treatment as separate species more appropriate. Often considered to include *O. seductus* and *O. cooperi* as races. Geographical limits of listed races require further study; *naevius* sometimes merged with nominate. Additional described races probably reflect individual variation or intermediates only: *swenki* of SC Canada to Oklahoma included in *maxwelliae*; *semplei* from C Mexico in *mccallii*. Six subspecies recognized.

Subspecies and Distribution.

O. a. maxwelliae (Ridgway, 1877) - SC Canada and NC USA.

O. a. naevius (J. F. Gmelin, 1788) - SE Canada and NE USA (S to North Carolina).

O. a. asio (Linnaeus, 1758) - Oklahoma E to South Carolina and Georgia.

O. a. hasbroucki Ridgway, 1914 - C Oklahoma to Texas.

O. a. floridanus (Ridgway, 1874) - Louisiana to Florida.

O. a. mccallii (Cassin, 1854) - S Texas to NE Mexico.

Descriptive notes. 16-25 cm; male 166 g, female 194 g. Extremely similar to *O. kennicottii*; differs in more prominent, blackish rim to facial disc, somewhat less coarsely patterned underparts, and pale grey-green or dull green-blue (not blackish) bill; also, rufous morph more common, mainly in S, and more bright "foxy" in colour, with all grey or brown replaced by bright cinnamon-rufous or chestnut-rufous, upperparts without vermiculations, blackish streaks narrower and linear, underpart pattern less intricate. Juvenile grey to brownish-grey (grey morph) or dull rusty-red (rufous morph), face uniformly coloured, ear-

tufts inconspicuous and unicoloured (adult tufts bicoloured), faint barring on head, mantle and underparts. Races show degree of clinal variation, tend to become smaller and darker from N & W to S & E: *naevius* largest, much white below; *maxwelliae* pale above, whitish below, rare red morph very pale; *hasbroucki* with broad flank barring; *floridanus* with red morph predominant, dark rusty-brown above, light rufescent below; *mccallii* much more heavily mottled than other races. VOICE. Primary song quavering, low-pitched descending trill, c. 4-6-8-8 notes/second, ending abruptly, repeated after few seconds; also whinnying secondary song; female higher-pitched, duets.

Habitat. Tree-dominated landscapes: early successional to mature, mountain slopes to river valleys, below 1500 m. Occurs in natural woodland and wooded suburban and urban habitats, e.g. deciduous and mixed forest, riparian and pine forest; oak-juniper (*Quercus-Juniperus*) and subtropical thorn woodland in S; urban and suburban parks and gardens. Where overlaps with *O. kennicottii* in Texas, found along permanent watercourses and at lower elevation, with latter species inhabiting seasonally wet upland drainage areas. Prefers open subcanopy space with sparse shrub cover that facilitates flying and foraging, and perhaps predator detection.

Food and Feeding. Diet among most varied of any Nearctic owl: terrestrial and aquatic invertebrates (primarily insects, crayfish, earthworms), and wide range of vertebrates (especially songbirds, rodents). Most hunting nocturnal, but often crepuscular, occasionally diurnal. Perches below tree canopy, makes straight perch-to-prey strike, captures with feet; rarely flycatches with bill. Can take prey hidden in leaf litter; catches fish and tadpoles in water less than 10 cm deep, feet-first, flying from perch or hopping from shore; hovers, and flushes quarry with wingbeats. Walks, runs and hops on ground after prey; chicks do same on leaving nest. Kills or disables prey on ground or perch, by biting and tugging on head and neck; birds partially plucked; with vertebrates, usually eats head before caching body.

Breeding. Season Mar-Sept. Monogamous, occasionally polygynous. Nest-site a deep cavity with small entrance and large floor (hollow trunk, stump or limb, or hole in same), c. 30% old holes of woodpeckers (Picidae), most the result of storm damage to tree, or naturally rotted and/or enlarged by squirrels; in one study, most frequent trees used were pear (*Pyrus*), cottonwood (*Populus*), oak (*Quercus*), elm (*Ulmus*) and pine (*Pinus*); artificial sites include nestboxes, mailboxes, porch columns, discarded boxes on ground, dove-cotes. Usually 3-4 eggs, but up to 7; infertile eggs sometimes removed from cavity and replaced; sequential mate of polygynous male may displace earlier female and add to existing clutch; incubation at least 26 days, by female; chick hatches with eyes closed, egg tooth prominent, whitish down; fledging 25-27 days; fledglings dependent on parents for 8-10 weeks, stay together, mostly in tree roosts, and fed by both parents. Annual number fledglings/nesting pair 2-6 in Michigan; in Texas, 1-9 (suburban) and 1-0 (rural). Most breed as yearlings. First-year survival in Texas estimated at 36% (suburban) and 30% (rural). Maximum recorded age 14 years and 2 months; average only 1 year in female *hasbroucki*.

Movements. Resident; may make local or altitudinal movements in severe winters or during food shortages.

Status and Conservation. Not globally threatened. CITES II. Long-term effects of human impacts on species as a whole doubtful. Pesticide-related eggshell-thinning and embryo mortality not found in wild, but can be induced in laboratory experiments. Reducing tree density below c. 50 trees/ha or removing natural cavities leads to species's total disappearance; tree-planting in deforested or naturally grassy areas fosters population expansion, although nestboxes required when trees young; human settlement with tree-planting possibly advantageous. Patchy habitat and riparian corridors suggest that partly disjunct local populations are metapopulations, some stable parts of

which may be source of immigrants for others unable to maintain stability. Urbanization and climatic warming may promote range expansion to N; moderate climate, enhanced and concentrated food supplies, constant water sources, and reduced number of predators (factors common to urban and suburban environments) considered beneficial.

46. Whiskered Screech-owl

Otus trichopsis

French: Petit-duc à moustaches

German: Fleckeneule

Spanish: Autillo Bigotudo

Other common names: Spotted Screech-owl, Whiskered Owl

Taxonomy. *Scops trichopsis* Wagler, 1832, Puebla, Mexico.

Relationships uncertain. Several additional races described: *pinosus* (Veracruz), *ridgwayi* (Michoacán) and *guerreroensis* (SW Mexico) included in nominate *trichopsis*; *pumilus* from Honduras in *mesamericanus*. Three subspecies recognized.

Subspecies and Distribution.

O. t. aspersus (Brewster, 1888) - SE Arizona to N Mexico (Sonora and Chihuahua).

O. t. trichopsis (Wagler, 1832) - highlands of C Mexico (from about Durango S to Veracruz, Oaxaca and Chiapas).

O. t. mesamericanus van Rossem, 1932 - SE Mexico (Chiapas) to NC Nicaragua.

Descriptive notes. c. 16-19 cm; male 70-105 g, female 80-120 g. Occurs in grey-brown and rufous morphs, latter more in S. Facial disc pale grey with faint dusky rings, area of deep brown immediately above eye, disc mostly bordered boldly with black; dark grey to brownish-grey above with blackish shaft streaks, scapulars with black-edged whitish to light buff outer webs; flight-feathers prominently barred pale; pale below, with dark vertical stripe down shaft of each feather, crossed by dark horizontal bars, streaks broadest on breast. Rufous morph with black streaks above, pale cinnamon-buff to light cinnamon-rufous

below with indistinct dusky bars on flanks. Tarsus fully feathered; iris yellow; bill grey. Juvenile duller above, with indistinct barring or transverse mottling, dull white underparts broadly barred grey-brown. Racial variation shows trend from NW to SW from grey through blackish to brown, from medium to coarse to fine markings, increase of rufous decoration of grey morph, and appearance of rufous morph in S: *aspersus* light grey; *mesamericanus* rufous-brown, with black dorsal cross-bars. VOICE. Primary song a series of c. 8 evenly spaced "boot" or "boo" notes, uniform in pitch or slight drop at end, lasting up to almost 3 seconds; secondary song 2 short and closely spaced notes, followed by 2-5 longer notes; female versions of both higher-pitched; calls include a "chang," a trill and a "shee".

Habitat. Occurs in dense groves of oaks within pine-oak zone of montane vegetation; prefers denser groves and higher elevations than *O. asio*. In Arizona and parts of Mexico, ranges down into dense oaks below pine zone; in S Mexico and El Salvador, also above pine forest to lower parts of cloudforest; also in El Salvador, occurs within coffee plantations, where it breeds in tall shade trees, occupying groves and thickets remaining after incomplete logging has opened up denser forest. From 750 m to c. 2500 m.

Food and Feeding. Primarily insects, usually winged; among favoured prey are grasshoppers (Acrididae, Tettigoniidae), beetles (*Phyllophaga*), moths (Phalaenidae, Zanolidae); centipedes (*Scopelendra*) evidently an important winter food, at least locally; stomach contents included a mouse. Nocturnal. Hunts from perch in tree, making short, straight flight to winged prey from an exposed branch; commonly flutters back and forth in tops of trees, catching insects in succession, with relatively little pause between captures; prey occasionally taken on ground, on dead branch of a neighbouring tree, or on vegetation.

Breeding. Eggs found in Apr and May. Few nests located, all in natural cavity or old hole of flicker (*Colaptes*), 5-5-6 m above ground in tree (recorded in oak, walnut, juniper and sycamore). 3-4 eggs; incubation by female; no other information.

Movements. Probably resident, occurring too far S to be significantly affected by winter reduction in insect populations; perhaps some vertical migration to lower elevations during winter, at least in N of range.

Status and Conservation. Not globally threatened. CITES II. Common to fairly common. Fire suppression in mountains of S Arizona, resulting in thickening of woodland and forest growth, may have increased its distribution at expense of *O. asio*; species will probably continue to abound wherever dense vegetation allowed to remain on steep N-facing mountainsides and in narrow, shady canyons. In Mexico, where naturally occurring fires not curbed, more open forest favours *O. asio* and *O. flammeolus*; logging further opens up growth, restricting species to dense stands remaining on steep slopes and in deep canyons. Overall, occupies any groves and pockets remaining after incomplete logging and in areas partly opened up for agriculture; in El Salvador, can live within coffee plantations, in artificial forest of tall shade trees. Population or trends little known, but clearly dependent on the future of fairly dense montane forest within its range.

Bibliography. Baicich & Harrison (1997), Binford (1989), Eckert (1997), Heintzelman (1992), Howell & Webb (1995a), Johnsgard (1988), Kaufman (1996), Kaufman & Bowers (1989), Land (1970), Ligon & Brenowitz (1976), Martin (1974), Monroe (1968), Ridgely & Gwynne (1989), Ross (1969), Rowley (1984), Schaldach (1963), Smith *et al.* (1982), Stotz *et al.* (1996), Tyler & Phillips (1978), Voous (1988), Wolfe & de la Torre (1990).

47. Tropical Screech-owl

Otus choliba

French: Petit-duc choliba **German:** Cholibaeule **Spanish:** Autillo Chóliba
Other common names: Choliba Screech-owl

Taxonomy. *Strix choliba* Vieillot, 1817, Paraguay. Relationships unclear; appears to have no close affinities with any other *Otus*. Has in past included *O. koepckeae* and *O. roboratus* as races, but those both clearly distinct in morphology and/or vocalizations. Several additional races described, probably only morphs or result of individual variation: *montanus*, *kelsoi*, *alticola*, *cauca*, *guyanensis* and *portoricensis* included in *crucigerus*; *caatingensis* in *decussatus*; *chapadensis* in nominate *choliba*; *alilucoco* in *wetmorei*. Nine subspecies recognized.

Subspecies and Distribution.

O. c. luctisomus Bangs & Penard, 1921 - Costa Rica to NW Colombia, including Pearl Is.
O. c. margaritae Cory, 1915 - Margarita I, off N Venezuela.
O. c. choliba (Vieillot, 1817) - S Brazil (S Mato Grosso, São Paulo) to E Paraguay.
O. c. wetmorei Brodtkorb, 1937 - W Paraguay and N Argentina (S to Mendoza, N Buenos Aires and N Rio Negro).
O. c. uruguayensis Hekstra, 1982 - NE Argentina, SE Brazil (Santa Catarina, Rio Grande do Sul) and Uruguay.

Descriptive notes. 20-24 cm; 97-160 g. Occurs in grey-brown, brown and rufous morphs, with intermediates, and much individual variation; rufous morph scarce. Facial disc light grey with prominent broad black border; crown and upperparts heavily streaked dark, scapulars with dark-edged pale spots; flight-feathers and tail barred light buff and brown; underparts white, thinly vermiculated with brown and small amounts of buff, with black shaft streaks throughout, each feather with fishbone-like pattern; tarsus feathered, toes completely bare; iris yellow; bill greenish-grey with grey tip; feet grey-brown. Juvenile mostly buffy, finely

barred dusky, darker above. Races differ mainly in size, though minimal, and plumage differences difficult to assess owing to range of variation; *duidae* very dark, with pale collar on hindneck. Voice. Primary song a brief trill followed by 2, occasionally 1 or 3, louder toots. "prrrr pu POO, prrrr POO poo, prrrr p'p' poo"; sometimes trill or toots alone; secondary song bubbling "bububububu"; calls include strident screeching barks, "kwah-hwah-kwah".

Habitat. Timbered savanna, gallery forest, forest clearings and edge, and semi-open areas with scattered trees, second-growth thickets, plantations; also town and suburban parks. Generally from sea-level to c. 1500 m; in Costa Rica to 700 m; in Colombia to 2800 m, but sightings reported at up to 3000 m; in Argentina locally to 2700 m, but usually at lower levels; records at higher altitudes apparently dependent on favourable climatic conditions.

Food and Feeding. Mostly insects, especially large orthopterans such as grasshoppers and crickets, as well as scarabids, bumblebees, moths; also spiders and scorpions, earthworms; occasionally snakes (*Helminthophis*), and sometimes small mammals such as rats (*Oryzomys*); bats also taken. Forages at lower levels, usually from perch, often along roadside; captures prey on branches or on ground; often snatches insects in air, especially at electric lights.

Breeding. Lays Jan-Jul, regularly May; Sept-Oct in S. Nest in any kind of cavity, natural or old woodpecker hole; also uses abandoned boxes. Usually 1-4 eggs, but 6 reported in Argentina; incubation by female; chick with whitish down; in Costa Rica, young left nest when 30 days old (in Mar).

Movements. Little known; probably resident.

Status and Conservation. Not globally threatened. CITES II. Widely distributed and rather common; most common screech-owl in Costa Rica and Panama; fairly common in Brazil, Argentina and Uruguay. Little is known, however, about its population levels and ecology. Habit of hunting along roadsides makes it vulnerable to traffic; mortality on roads quite high in some places. Some local human persecution.

Bibliography. Belton (1984), Browning (1990), Canevari *et al.* (1991), Contreras (1983), Contreras *et al.* (1990), Fjeldså & Krabbe (1990), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Klimaitis & Moschione (1987), König (1994b), Meyer de Schauensee & Phelps (1978), Monroe (1968), Olrog (1985), de la Peña (1994), Piacentini & Acebo (1998), Ridgely & Gwynne (1989), do Rosário (1996), Saibene *et al.* (1996), Short (1975), Sick (1993, 1997), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Thomas (1977), Tostain *et al.* (1992), Wetmore (1968a).

48. Koepcke's Screech-owl

Otus koepckeae

French: Petit-duc de Koepcke **German:** Andenkreischeule **Spanish:** Autillo de Koepcke
Other common names: Maria Koepcke's Screech-owl

Taxonomy. *Otus choliba koepckeae* Hekstra, 1982, Cordillera Blanca, Peru.

Originally described as race of *O. choliba*, but distinctly different in morphology; taxonomy requires further study to clarify true relationships. Species name sometimes incorrectly spelt *koepcke*. Monotypic.

Distribution. NW Peru (probably from around Amazonas, and Ancash S to Lima, possibly farther S, to Ayacucho or beyond); apparently also WC Bolivia (to La Paz). Distributional limits very imperfectly known.

Descriptive notes. c. 24 cm; c. 110-120 g. Resembles *O. roboratus*; differs in larger size, paler crown and forehead, less obvious nuchal collar, broader and more prominent shaft

streaks below, light ochre-brown wash across neck sides and breast. Juvenile unknown. Voice. Not described.

Habitat. Wooded areas and arid forest patches on Andean slopes, up to *Polylepis* woodland, in upper montane zone at 2500-4500 m.

Food and Feeding. No information. Probably insects.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Very poorly known; no information on numerical status, ecology or biology. Warrants classification as Data-deficient.

Bibliography. Fjeldså & Krabbe (1990), Hekstra (1982b), Stotz *et al.* (1996).

49. Peruvian Screech-owl

Otus roboratus

French: Petit-duc du Pérou **German:** Buscheule **Spanish:** Autillo Peruano
Other common names: West Peruvian/Roborate Screech-owl; Coastal/Tumbes Screech-owl (*pacificus*)

Taxonomy. *Otus roboratus* Bangs and Noble, 1918, Bellavista, Peru.

Has been treated as conspecific with *O. choliba*, but vocalizations distinct. Smaller race *pacificus* suggested as possibly separate species; further study needed. Two subspecies recognized.

Subspecies and Distribution.

O. r. pacificus Hekstra, 1982 - SW Ecuador and extreme NW Peru (S to Lambayeque).
O. r. roboratus Bangs & Noble, 1918 - extreme S Ecuador and NW Peru between W & C Andes (drainage of R Chinchipe and R Marañón).

Descriptive notes. c. 20-22 cm, 144-162 g (*roboratus*); c. 70-90 g (*pacificus*). Occurs in grey-brown and rufous morphs. Facial disc greyish-white, narrowly barred dusky, with black border; small ear-tufts grey-white and warm brown; crown blackish-brown, giving capped effect, contrasting strongly with white eyebrows; distinct pale nuchal collar; upperparts grey-brown, slightly barred dark, with blackish shaft streaks; inner wing with narrow cinnamon-brown bars and dusky speckles; scapulars with black-edged whitish outer webs; flight-feathers barred buffy-white; underparts whitish, faintly vermiculated, with variable but

often fine dark shaft streaks with lateral bars, central belly often clear white; tarsus fully feathered; iris yellow to golden; bill grey with yellow tip; feet greyish. Rufous morph pale rufous with dark brown markings. Juvenile densely barred, iris pale yellow-olive. Race *pacificus* smaller, less heavy, averages paler and greyer but much overlap; rufous morph commoner than in nominate. Voice. Typical song a harsh, rising trill, marginally increasing in frequency towards end, lasting c. 2-5 seconds; *pacificus* said to give rapid series of notes, rising in volume in middle, dropping slightly and then fading, c. 1-5 seconds long; in aggression, series of short upward-inflected yelps, and from *pacificus* downslurred "kii".

Habitat. Dry deciduous woodland with scattered bushes on mountain slopes and in hilly country, mostly at 500-1200 m, occasionally higher. Race *pacificus* inhabits arid coastal plains and foothills, generally below 500 m; habitats range from open, dry scrub of various shrubs, cacti, mesquite and various short trees, to dry deciduous forest of small to medium-sized trees and columnar cactus (*Cereus*); other typical species include *Capparis*, *Acacia*, *Prosopis* and *Bombax*.

Food and Feeding. Largely insectivorous, perhaps almost exclusively so; known to take caterpillars, orthopterans, grasshoppers, crickets, and beetles and their larvae. Nocturnal.

Breeding. Nest in cavity of moderate-sized tree; no other information.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. Can be very common locally, but overall rare and possibly vulnerable; both N and S limits of distribution, however, uncertain. Since early 1970's, much habitat rendered unsuitable by effects of grazing by goats, and by cutting of trees and shrubs for firewood and for charcoal production; although able to occupy very sparse woodland and scrub, at least for foraging, and probably to lesser extent for roosting, species may not be able to survive in such open habitat without trees of at least moderate stature that can provide nesting cavities. Because of pastoral economy typical of region, goat browsing and firewood-gathering difficult to control; however, harvesting for charcoal could be discouraged wherever possible.

Bibliography. Best & Kessler (1995), Best *et al.* (1993), Cook (1996), Fjeldså & Krabbe (1990), Johnson & Jones (1985, 1990), Koepcke (1970), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Pople *et al.* (1997), Stotz *et al.* (1996), Taylor (1995), Williams & Tobias (1996), Williams *et al.* (1996).

50. Bare-shanked Screech-owl

Otus clarkii

French: Petit-duc de Clark **German:** Nacktbeineule **Spanish:** Autillo Serrano

Taxonomy. *Otus clarkii* L. Kelso and E. H. Kelso, 1935, Calobre, Panama.

Relationships unknown. Monotypic.

Distribution. Costa Rica S to extreme NW Colombia.

Descriptive notes. 20-25 cm; 125-180 g. Large screech-owl with large head, ear-tufts smaller than most other *Otus*. Face cinnamon with poorly defined facial rim; rufous-brown above, spotted blackish, hindneck more buff, scapulars with blackish-edged outer webs; flight-feathers barred; underparts darkish, throat and breast buffy-brown with buff-white spots and black streaks, belly with more white; only upper two-thirds of tarsus feathered, lower section and toes bare; iris yellow; bill grey; lower tarsus and toes greyish-flesh. Juvenile cinnamon-buff above, speckled with white and barred dusky, buffy-white below with dull cinnamon bars.

VOICE. Primary song a deep "wook wook wook", repeated at intervals of few seconds; secondary

song deep whistled "hu-hu, HOO-HOO hoo", penultimate note usually highest; female songs slightly higher-pitched, often in duet; call rather high, musical, hooting "coo, coo-coo-coo".

Habitat. Cloudforest and humid, dense mountain forest and forest edge; sometimes occurs in thinner upland forest. From 900 m to c. 2350 m, occasionally to 3300 m.

Food and Feeding. Mainly large insects, including crickets, grasshoppers and beetles, also spiders; some shrews and small rodents also taken. Hunts at dusk and at night, along edges, in clearings and sometimes in canopy. Prey normally captured on ground or on branches; observed to take insects close to artificial lights.

Breeding. Little known. Lays mid Feb-May; fledged young seen May-Aug. Only known nest was in natural cavity in oak (*Quercus copeyensis*).

Movements. Presumably resident.

Status and Conservation. Not globally threatened, CITES II. Restricted-range species: present in Costa Rica in several protected areas, such as Volcán Poás National Park and Monteverde Biological Reserve, and occurs in Panama Highlands EBA and Darién Highlands EBA. Considered uncommon; little known about population level. Needs at least patchy forest; in Costa Rica, habitat adversely affected by development of dairy industry. With restricted distribution in mountains in Middle America, and possible threats to habitat, conservation status of species should probably be reassessed.

Bibliography. Anon. (1998a), Hilty & Brown (1986), Olog (1968), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Slud (1964), Stattersfield *et al.* (1998), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

51. Bearded Screech-owl

Otus barbarus

French: Petit-duc bridé

German: Tropfeneule

Spanish: Autillo Barbudo

Other common names: Bridled/Santa Barbara Screech-owl

Taxonomy. *Scops barbarus* P. L. Slater and Salvin, 1868, Santa Barbara, Vera Paz, Guatemala. Relationships uncertain; has been considered ecological counterpart of *O. flammeolus*. Monotypic.

Distribution. Highlands of S Mexico (Chiapas) and N Guatemala.

Descriptive notes. 16-20 cm; c. 70 g. Small screech-owl with very small ear-tufts; wings project beyond short tail. Occurs in brown and rufous morphs. Pale facial disc with thin dark border; spotted with brown, white and black above, white spots heavier on upper mantle, scapulars with black-edged whitish outer webs; flight-feathers strongly barred; breast densely barred brown and buff, fading to white with light barring on flanks and belly, with dark shaft streaks throughout; tarsus feathered; iris yellow; bill greenish-grey; toes pinkish-grey. Rufous morph less patterned, dark markings more reddish-brown. Juvenile barred. **VOICE.**

Short fast trill of 3-5 seconds' duration, increasing in volume, at times dropping abruptly at end; also soft ventriloquial "hu".

Habitat. Highland pine and pine-oak forest, and cloudforest, from 1400 m to 2500 m above sea-level, mostly above 1800 m.

Food and Feeding. Mainly large insects.

Breeding. Nest undescribed; 4-5 eggs; no other information.

Movements. Resident.

Status and Conservation. Not globally threatened, CITES II. Restricted-range species: present in North Central American Highlands EBA. Currently considered Near-threatened. Considered fairly common but very local. Population level unknown, but possibly decreasing. In Chiapas, habitat apparently becoming fragmented. Requires research on its biology and ecology in order for true conservation status to be assessed.

Bibliography. Anon. (1998a), Hernández-Baños *et al.* (1995), Howell & Webb (1995a), Land (1970), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

52. Rufescent Screech-owl

Otus ingens

French: Petit-duc de Salvin **German:** Salvineule **Spanish:** Autillo Pálido
Other common names: Salvin's Screech-owl; Chapman's Screech-owl ("*aequatorialis*"); Least Screech-owl ("*minimus*")

Taxonomy. *Scops ingens* Salvin, 1897, Jima, Ecuador.

Relationships uncertain. Often considered to include *O. colombianus* as race; *O. petersoni* treated as conspecific by some authors. Forms described from E Ecuador (*aequatorialis*) and Bolivia (*minimus*) now thought to represent individual variation, synonymized with nominate. Two subspecies recognized.

Subspecies and Distribution.

O. i. venezuelanus Phelps & Phelps, Jr., 1954 - N Colombia and NW Venezuela.

O. i. ingens (Salvin, 1897) - Andes from NE Ecuador to WC Bolivia.

Descriptive notes. 24-28 cm; male 134-180 g, female 140-223 g. Large, rather uniform-looking screech-owl with vestigial ear-tufts, large brown eyes. Occurs in brown and rufous morphs. Facial disc buffy-brown, with indistinct rings and weakly defined border, usually with pale (but not white) eyebrows; upperparts tawny-olive to light grey-brown, or sandy-rufous, with fine dark vermiculations, few whitish spots, and whitish scapular line; underparts light buffish-white, finely barred light brown and white, with a few widely spaced dark brown streaks; tarsus fully feathered; iris brown; bill olive to yellow-grey; toes yellowish.

grey to pink. Juvenile with dense dusky mottling, also indistinct mask. Race *venezuelanus* slightly smaller, paler than nominate. **Voice.** Primary song a long rapid series of "tu" notes, c. 50 in 10 seconds; secondary song an almost even-pitched series suddenly accelerating after c. 4 notes, "hu hu hu hu tutututu".

Habitat. Dense, humid cloudforest and scrub on steep Andean slopes, at 1200-2250 m.

Food and Feeding. Poorly known; presumed to take primarily insects. Strictly nocturnal. Apparently forages in middle storey and canopy.

Breeding. No reliable information.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. Status is uncertain, and species little known; may be rare, unless overlooked. Occurs in at least two protected areas in Colombia, i.e. La Planada and Río Nambi National Reserves. Forest destruction probably a threat in some parts of range. Conservation status in need of review.

Bibliography. Fitzpatrick & O'Neill (1986), Fjeldså & Krabbe (1990), Fjeldså & Mayer (1996), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Olrog (1968), Stotz *et al.* (1996), Wetmore (1968b).

53. Colombian Screech-owl

Otus colombianus

French: Petit-duc de Colombie **German:** Kolumbieneule **Spanish:** Autillo Colombiano

Taxonomy. *Otus colombianus* Traylor, 1952, El Tambo, 5000 feet [c. 1700 m], Cauca, Colombia. Often treated as race of *O. ingens*. Sometimes *O. petersoni* treated as race of present species. Monotypic.

Distribution. W slope of Andes from WC Colombia to NW Ecuador.

Descriptive notes. 26-28 cm; male 150-156 g, female c. 210 g. Occurs in grey-brown and rufous morphs. Very similar to *O. ingens*; differs in having longer tarsus which is also bare distally; scapular stripe often less distinct, more buffish; flight-feathers and underparts without white. **Voice.** Much as *O. ingens*; whether vocally distinct from latter still debated.

Habitat. Cloudforest with dense understorey, at c. 1300-2300 m.

Food and Feeding. Large insects and small vertebrates.

Breeding. No reliable information.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Chocó EBA. Currently considered Near-threatened. Status uncertain, and species little known; may be rare. Forest destruction probably a threat, at least locally. Conservation status perhaps in need of review.

Bibliography. Fitzpatrick & O'Neill (1986), Fjeldså & Krabbe (1990), Hilty (1997), Hilty & Brown (1986), Kirwan & Marlow (1996), Olrog (1968), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

54. Cinnamon Screech-owl

Otus petersoni

French: Petit-duc de Peterson **German:** Zimtkreiseule **Spanish:** Autillo de Peterson

Taxonomy. *Otus petersoni* Fitzpatrick and O'Neill, 1986, Cordillera del Cóndor, Peru.

Possibly forms superspecies with *O. marshalli*; both formerly included under invalid name *O. huberi*. Alternatively, considered by some to be conspecific with *O. ingens* or *O. colombianus*. Scientific name sometimes incorrectly spelt as *petersenii*. Monotypic.

Distribution. Cordillera del Cutucú in SE Ecuador S to La Peca region in NW Peru.

Descriptive notes. c. 21 cm; male 88-119 g, female 92-105 g. Relatively small, with medium-length ear-tufts. Entire plumage warm buff-brown to cinnamon-brown; facial disc with lighter chin and eyebrows, indistinct darker rim; upperparts finely vermiculated, scapulars with light cinnamon outer webs; flight-feathers and tail barred; underparts slightly paler than upperparts, more cinnamon, with darker shaft streaks; tarsus feathered almost to toes; iris dark brown; bill greenish-grey; toes pinkish. Distinguished from *O. colombianus* by smaller size, deeper cinnamon coloration, more extensive tarsal feathering. Juvenile undescribed. **Voice.** Presumed primary song a rapid series of simple notes, c. 5-7 per second, rising slightly and then dropping, and ending abruptly, whole phrase c. 5-6 seconds long; also "wew" calls.

Habitat. Cloudforest with dense undergrowth, rich in epiphytes and mosses, at c. 1700-2500 m.

Food and Feeding. Mainly insects; probably some small vertebrates.

Breeding. Season probably May-Jun; no other information.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Ecuador-Peru East Andes EBA. Very poorly known, and no information on numbers; described as probably rare. Destruction of forest habitat probably a long-term threat. Conservation status in need of revision.

Bibliography. Clark & Mikkola (1989), Fitzpatrick & O'Neill (1986), Fjeldså & Krabbe (1990), Rahbek *et al.* (1995), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taylor (1995), Williams *et al.* (1996), Vuilleumier *et al.* (1992).

55. Cloudforest Screech-owl

Otus marshalli

French: Petit-duc de Marshall **German:** Nebelwald-Kreiseule **Spanish:** Autillo de Marshall

Taxonomy. *Otus marshalli* Weske and Terborgh, 1981, Cordillera Vilcabamba, 2180 m, Cuzco, Peru. Possibly forms superspecies with *O. marshalli*; both formerly included under invalid name *O. huberi*. Monotypic.

Distribution. C & S Peru in Pasco (Cordillera Yanachaga) and Cuzco (Cordillera Vilcabamba).

Descriptive notes. 20-23 cm; c. 115 g. Rather small, with short ear-tufts. Facial disc rufous, border black at sides, with white eyebrows; crown and upperparts rich rufous-brown, with transverse pattern of blackish mottling, and buffy nuchal collar; scapulars with blackish-tipped buffy to whitish outer webs; flight-feathers and tail barred; breast rufous with dark shaft streaks and thin vermiculations; lower breast and belly off-white with dark streaks and thin cross-bars, appearing almost "ocellated"; tarsus fully feathered; iris dark brown; bill greenish-grey; toes flesh-pink. Differs from *O. ingens* in smaller size, more strongly patterned

underparts. Juvenile much as adult. **Voice.** Presumed primary song a rather fast, regular series of "ii" notes, phrase c. 5-10 seconds long, repeated after short interval.

Habitat. Humid, mossy cloud forest with epiphytes, ferns and dense undergrowth, generally at 1900-2500 m, possibly higher; occurs at slightly higher elevations than *O. ingens*.

Food and Feeding. Probably insectivorous; forages in canopy; needs further study.

Breeding. Little information. Appears to breed in late Jun-Aug, sometimes earlier; male collected in early Mar was not in breeding condition.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Peruvian East Andean Foothills EBA. Poorly known; thought to be not uncommon locally, but no indication of numbers. Destruction of forest habitat probably a long-term threat. Conservation status perhaps in need of revision.

Bibliography. Clark & Mikkola (1989), Fitzpatrick & O'Neill (1986), Fjeldså & Krabbe (1990), Parker *et al.* (1982), Schulenberg *et al.* (1984), Shuker (1993), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier *et al.* (1992), Weske & Terborgh (1981).

56. Tawny-bellied Screech-owl

Otus watsonii

French: Petit-duc de Watson **German:** Watsoneule **Spanish:** Autillo del Amazonas
Other common names: Austral/Southern Screech-owl (*usta*)

Taxonomy. *Ephialtes Watsonii* Cassin, 1848, Orinoco River, Venezuela.

Suggested to belong to the *O. atricapillus* superspecies, but large overlap in range with *O. vermiculatus*. From vocal evidence and DNA sequencing appears closest to *O. atricapillus*; more distantly related to *O. choliba* than previously thought. Race *usta* has been treated as separate species; compared with nominate, however, differences in morphology appear to be minimal and vocal dissimilarities probably not constant; also, their ranges may partly overlap. Two subspecies recognized.

Subspecies and Distribution.

O. w. watsonii (Cassin, 1848) - lowlands from E Colombia S to NE Peru and E (N of R Amazon) to Surinam and Amazonian Brazil.

On following pages: 57. Guatemalan Screech-owl (*Otus guatemalae*); 58. Vermiculated Screech-owl (*Otus vermiculatus*); 59. Hoy's Screech-owl (*Otus hoyi*); 60. Variable Screech-owl (*Otus atricapillus*); 61. Long-tufted Screech-owl (*Otus sanctaecatarinae*); 62. Puerto Rican Screech-owl (*Otus nudipes*); 63. White-throated Screech-owl (*Otus albugularis*); 64. Palau Owl (*Pyrroglaux podarginus*); 65. Cuban Screech-owl (*Gymnoglaux lawrencii*); 66. Northern White-faced Owl (*Ptilopsis leucotis*); 67. Southern White-faced Owl (*Ptilopsis granti*); 68. Giant Scops-owl (*Mimizukura gurneyi*).

O. w. usta (P. L. Sclater, 1859) - E Peru and S Amazonian Brazil S to lowland forest of N Bolivia and N Mato Grosso.

Descriptive notes. 19-24 cm; c. 115-155 g. Facial disc and eyebrows brown-buff, with faint blackish vermiculations and thin dark border; longish, broad ear-tufts with black outer webs and tips; crown and upperparts dark grey-brown, spotted and vermiculated with black and buff, hint of buff on hindneck; scapular spots indistinct or lacking; flight-feathers and tail barred brown and light buff; breast dark brown with small buff spots; rest of underparts buff, streaked with black, with obscure white barring on belly; tarsus fully feathered buff; iris brownish-orange to yellow; bill green-grey; toes yellow-brown to pinkish-grey. Juvenile undescribed. Race *usta*

similar in pattern, but slightly smaller, rufous overall, broader streaks below; also occurs in browner and buffer morphs. **Voice.** Primary song soft, low and full, beginning with monotonous "whooh" notes, becoming faster and louder, then fading with low trill, phrase c. 20 seconds long; secondary song brief series of short "wu" notes. Race *usta* primary song similar, c. 2 notes per second; secondary song thought to be fast series of "bu" notes, slowing to "bouncing" rhythm at end.

Habitat. Interior of lowland rainforest, especially old-growth primary forest and mature second growth; occasionally in clearings or at edge; *usta* also inhabits remnant forest along rivers. Lives in lower storey of forest, usually found no more than 30 m above the ground, often descending into undergrowth. Generally at elevations not exceeding c. 600 m.

Food and Feeding. Mostly insects; probably also terrestrial vertebrates. Forages in the lower levels. **Breeding.** No information.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Status uncertain, and species poorly known. Since it seems to be restricted to forest, the major threat to its survival must surely be destruction of its habitat. Nominate race occurs in several protected areas, such as Amacayacu National Park in Leticia, Colombia, and Imataca Forest Reserve in Bolívar, Venezuela. Conservation status in need of revision.

Bibliography. Blake (1962), Fitzpatrick & O'Neill (1986), Friedmann (1948), Haverschmidt & Mees (1994), Heidrich *et al.* (1995b), Hekstra (1982a), Hilty & Brown (1986), Kirwan & Sharpe (1999), König (1994b), Meyer de Schauensee & Phelps (1978), Olrog (1968), Robinson & Terborgh (1997), Sargeant (1994a), Schmitt *et al.* (1986), Sick (1993, 1997), da Silva *et al.* (1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Willard *et al.* (1991).

57. Guatemalan Screech-owl

Otus guatemalae

French: Petit-duc guatémalteque **German:** Rotgesichteule **Spanish:** Autillo Guatemalteco
Other common names: Middle American Screech-owl

Taxonomy. *Scops guatemalae* Sharpe, 1875, Guatemala.

Perhaps a member of a superspecies, along with *O. vermiculatus*, *O. hoyi*, *O. atricapillus* and *O. sanctaecatarinae*. Sometimes considered conspecific with *O. atricapillus*; has been treated as conspecific with *O. vermiculatus*, but vocally distinct. Races *tomlini*, *fuscus* and *thompsoni* possibly inadequately differentiated to merit subspecific status; proposed races *pettingilli* and *peteni* included in *hastatus* and nominate *guatemalae* respectively. Seven subspecies recognized.

Subspecies and Distribution.

- O. g. tomlini* R. T. Moore, 1937 - NW Mexico (S Sonora and SW Chihuahua S to Sinaloa).
- O. g. hastatus* (Ridgway, 1887) - SW Sinaloa to Oaxaca.
- O. g. cassini* (Ridgway, 1878) - E Mexico (S Tamaulipas and N Veracruz).
- O. g. fuscus* R. T. Moore & J. L. Peters, 1939 - Veracruz.
- O. g. thompsoni* Cole, 1906 - Yucatán Peninsula and Cozumel I.
- O. g. guatemalae* (Sharpe, 1875) - SE Mexico (S Veracruz and NE Oaxaca) to Honduras.
- O. g. dacrysiactacus* R. T. Moore & J. L. Peters, 1939 - N Nicaragua.

Descriptive notes. 20-23 cm; 100-150 g. Occurs in brown and rufous morphs. Brown morph with facial disc light brown and lightly barred white, with thin dark border, thin white eyebrows contrasting with short dark ear-tufts; indistinct pale nuchal collar; crown heavily spotted and barred blackish; upperparts relatively dark grey-brown to blackish-brown with darker vermiculations and streaks, scapulars with black-edged whitish outer webs; flight-feathers and tail barred; paler below, with blackish shaft streaks and vermiculations, strongest on breast; tarsus fully feathered; iris yellow; bill greenish-grey; toes flesh-coloured. Rufous morph less

boldly patterned. Differs from *O. vermiculatus* in feathered lower tarsus, stronger markings. Juvenile similar to adult, faintly barred. Races differ in tone of coloration and in size, which increases from N to SE: *cassini* smallest, also darkest; *dacrysiactacus* pale; *hastatus* intermediate. **Voice.** Primary territorial song a quavering trill, c. 14 notes per second, increasing in pitch and volume, ending abruptly, usually 6-15 but up to 20 seconds in duration; secondary song short series of notes, speeding up in bouncing-ball rhythm.

Habitat. Humid lowland to semi-arid evergreen forest, semi-deciduous forest and thorn forest; also dense second growth and similar scrub and plantations. From sea-level to 1500 m.

Food and Feeding. Mainly large insects, such as beetles, katydids, orthopterans; also frogs, reptiles and fish; sometimes rodents. Nocturnal hunter, using forest clearings and edge. Hunts from perch, swooping on to prey on ground or branch; also catches insects in flight.

Breeding. Lays mostly Mar-Apr, but incubation recorded in Jun in Yucatán Peninsula; juveniles observed in Jun. Nest in cavity of tree, often old woodpecker hole; recorded in old nest of trogon (*Trogon*). 3 eggs (2-5); incubation by female.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Little information available; appears to be not rare locally. Has been recorded at San Blas (Nayarit), El Sumidero and Bonampak (Chiapas) and Cobá and Felipe Carrillo Puerto (Quintana Roo). Populations have probably declined as a result of forest destruction. Habitat loss a threat, at least in long term.

Bibliography. Anon. (1998a), Binford (1989), Heidrich *et al.* (1995b), Howell & Webb (1995a), König (1991a), Land (1970), Monroe (1968), Ridgely & Gwynne (1989), Schaldach (1963), Sutton & Pettingill (1942), Stiles & Skutch (1989), Stotz *et al.* (1996), Voous (1988).

58. Vermiculated Screech-owl

Otus vermiculatus

French: Petit-duc vermiculé **German:** Bänderkreischeule **Spanish:** Autillo Vermiculado

Taxonomy. *Megascops vermiculatus* Ridgway, 1887, Costa Rica.

Perhaps a member of a superspecies, along with *O. guatemalae*, *O. hoyi*, *O. atricapillus* and *O. sanctaecatarinae*. Sometimes considered conspecific with *O. guatemalae*, but vocally distinct. Isolated races *roraimae* and *napensis* possibly separate species; further study needed. Additional races described from Peru (*helleri*) and Bolivia (*bolivianus*) here merged with *napensis*, but possibly merit subspecific recognition. Three subspecies recognized.

Subspecies and Distribution.

- O. v. vermiculatus* (Ridgway, 1887) - NE Costa Rica to NW Colombia, N Venezuela.
- O. v. roraimae* (Salvin, 1897) - S Venezuela and N Brazil (mountain regions of Roraima, Duida and Neblina).
- O. v. napensis* Chapman, 1928 - E Ecuador to Peru, and N Bolivia.

Descriptive notes. 20-23 cm; c. 100-110 g. Occurs in brown and rufous morphs. Brown morph with facial disc light brown with thin dark rings, indistinct border, pale eyebrows obscure; greyish-brown to buffy-brown above, finely and uniformly vermiculated with black; scapulars with white outer webs; flight-feathers prominently barred; whitish below, densely and finely vermiculated with black and brown, with some dark shaft streaks; tarsus feathered almost to toes; iris deep yellow; bill grey-green; toes pinkish-grey. Rufous morph bright uniform rufous above and on head. Distinguished from *O. guatemalae* by bare lower

tarsus, less strongly patterned plumage. Juvenile dull buffy-brown, abdomen and flanks with down feathers tipped greyish-white. Race *roraimae* darker, more heavily patterned; *napensis* with distinct white eyebrows, sometimes brown eyes. **Voice.** Primary song very fast, long, toad-like trill, starting softly, becoming louder, then dropping in pitch and fading out towards end; female may answer with shorter, higher trill; probable secondary song a very brief descending purr; also "ghoor" or "khoo" calls. Races *roraimae* and *napensis* similar to *O. guatemalae*, but song shorter.

Habitat. Humid tropical forest in lowlands and foothills, to c. 1200 m. Race *roraimae* inhabits rainforest on mountain slopes, at 1000-1800 m; *napensis* mostly above 250 m, up to 1500 m.

Food and Feeding. Mainly large insects; probably also some small vertebrates.

Breeding. Lays during Mar in N. Nest in natural tree cavity or old nest hole of other bird. 3 eggs. **Movements.** Resident.

Status and Conservation. Not globally threatened. CITES II. Needs almost solid forest. Very little information; possibly not rare locally. Has been recorded at Finca La Selva, on the Caribbean lowlands of Costa Rica, and the Pipeline road, in central Panama. Forest destruction a threat, at least in long term.

Bibliography. Chapman (1931), Heidrich *et al.* (1995b), Hilty & Brown (1986), König (1994b), Marín & Schmitt (1991), Meyer de Schauensee & Phelps (1978), Ridgely & Gwynne (1989), Sargeant (1994a), Sick (1993, 1997), Slud (1960, 1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Voous (1988), Wetmore (1968a), van der Weyden (1974), Willis & Eisenmann (1979).

59. Hoy's Screech-owl

Otus hoyi

French: Petit-duc de Hoy **German:** Hoyeule **Spanish:** Autillo Fresco
Other common names: Montane Forest Screech-owl

Taxonomy. *Otus hoyi* König and Straneck, 1989, mountain forest at La Cornisa, c. 40 km north of the city of Salta, Argentina.

Perhaps a member of a superspecies, along with *O. guatemalae*, *O. vermiculatus*, *O. atricapillus* and *O. sanctaecatarinae*. Sometimes considered conspecific with *O. atricapillus*, but vocally distinct, and treatment as separate species supported by DNA evidence. Monotypic.

Distribution. Mountains of S Bolivia (S from Cochabamba) and NW Argentina (S to Tucumán, possibly to Catamarca).

Descriptive notes. 24 cm; 115-145 g. Occurs in grey, brown and rufous morphs. Facial disc grey-brown with fine, dark markings and white eyebrows, bordered in black; upperparts with dark vermiculations and streaks; small half-circle of white feathering at back of head; scapulars with long row of big white spots, many divided by a dark stripe; flight-feathers barred, tail with light brown stripes and vermiculations; underside light grey to grey-brown, washed with ochre-brown; breast and flanks with strong black shaft streaks; tarsus fully feathered grey-brown; iris bright deep yellow; bill yellow-green; toes grey-brown to

flesh. Grey morph distinctly grey-tinged, rufous morph rusty. Differs from grey morph of *O. chotiba* in less marked dark rim around facial disc, presence of white semi-circle on back of head, less bold markings. **Voice.** Primary song begins softly, gradually swells into rapid staccato of "u" notes, 11 per second, and tapers off at end; phrase c. 8 seconds, followed by pause of variable length according to intensity of vocal activity, then begins again; female higher-pitched, less full; pair duets; secondary song similar but short, ends abruptly, in excitement, loud long rising notes.

Habitat. Montane forest and cloudforest, in more or less moist areas with tall, thick trees and epiphytes; in SE Salta (Argentina), found only a few km from dry brush and trees in closed forest. Occurs at 1000-2600 m, locally to 2800 m.

Food and Feeding. Primarily insectivorous.

Breeding. Probably lays in Sept-Oct; in one study, main singing activity noted in last third of Sept; breeding probably dependent on onset of heavier rainfall, with subsequent flush of insects. Nest mainly in old woodpecker cavity; in one study, species found only in forest areas with such cavities, and pair occupied old hole of woodpecker 7 m above ground. No information on clutch size and other details.

Movements. Probably resident; some altitudinal movement to lower levels likely in winter.

Status and Conservation. Not globally threatened. CITES II. Appears not uncommon locally. Probably subject to some loss of habitat through deforestation, perhaps also overgrazing; will occupy forest patches on slopes where felling more difficult, which may aid future survival. Present in a number of protected areas in Argentina, such as El Rey National Park, Salta, and species is to some extent protected by the inaccessibility of parts of its range.

Bibliography. Babarskas *et al.* (1995), Canevari *et al.* (1991), Chebez (1994), Fjeldså & Mayer (1996), Heidrich *et al.* (1995b), Herzog *et al.* (1997), König (1991a, 1994b), König & Straneck (1989), Krabbe *et al.* (1996), Kratter *et al.* (1993), Mazar *et al.* (1997), Stotz *et al.* (1996), Straneck, Ridgely & Rodríguez (1987), Vuilleumier *et al.* (1992).

60. Variable Screech-owl

Otus atricapillus

French: Petit-duc à mèches noires **German:** Kappeneule **Spanish:** Autillo Capirotado
Other common names: Black-capped Screech-owl

Taxonomy. *Strix atricapilla* Temminck, 1822, Brazil.

Perhaps a member of a superspecies, along with *O. guatemalae*, *O. vermiculatus*, *O. hoyi* and *O. sanctaecatarinae*. Sometimes considered to include some or most of those as races, but all now shown to be vocally distinct, and treatment as separate species supported by DNA evidence. Southern populations have been sometimes separated as *argentinus*. Taxonomy of *Otus* in S Brazil and Argentine province of Misiones remains to be clarified. Monotypic.

Distribution. SE Brazil (S Bahia and Goiás S to Santa Catarina), SE Paraguay and extreme NE Argentina (N Misiones).

Descriptive notes. 23-24 cm; c. 115-140 g. Occurs in grey, brown and rufous morphs. Resembles *O. guatemalae*; differs in larger ear-tufts, darker crown, lighter facial disc with more distinct dark border, bolder streaks below, dark brown eyes; in grey and rufous morphs, iris sometimes dark golden-yellow or yellow-brown. Juvenile undescribed. **Voice.** Primary song a long fast trill, very faint before increasing in volume, ending abruptly, phrase 8-14 seconds, sometimes up to 20 seconds, repeated after some seconds; secondary song short, c. 2.5-3 seconds, in bouncing-ball rhythm; female higher-

pitched, primary song shorter; duets.

Habitat. Humid forest, especially extensive rainforest; partial to thick vine forest with dense undergrowth, and forest edge; occasionally more open woodland, sometimes near villages and roads. Mainly in lowlands, to at least 600 m in N of range; generally lower in S, to 300 m in Argentina.

Food and Feeding. Primarily insects, including beetles, locusts, cicadas and moths; probably also some small vertebrates. Forages in canopy, but frequently lower down, among undergrowth; takes prey from foliage, branches or the ground.

Breeding. 3 males with enlarged testes in Oct and Nov. Solitary, territorial, but at times almost semi-colonial, appears to breed in close proximity to conspecifics. Nest in tree cavity, including old woodpecker holes. No other details.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. May be locally fairly common; in Argentina, found to be locally common in N Misiones in 1950's, and possibly still common in e.g. Iguazú National Park. Currently considered uncommon to locally fairly common in Paraguay. Occurs in Aparados da Serra National Park, Rio Grande do Sul, but no data on population levels in Brazil. Species should be monitored because of the scale of habitat loss in its range; it seems to require fairly large areas of forest, and may not be able to survive in small remnant forest reserves.

Bibliography. Brooks *et al.* (1993), Canevari *et al.* (1991), Hayes & Scharf (1995b), Heidrich *et al.* (1995b), Hekstra (1982a), König (1991a, 1994b), Lowen, Barnett *et al.* (1997), Pacheco *et al.* (1996), do Rosário (1996), Saibene *et al.* (1996), Sick (1993, 1997), Stotz *et al.* (1996).

61. Long-tufted Screech-owl

Otus sanctaecatarinae

French: Petit-duc à aigrettes longues **Spanish:** Autillo de Santa Catarina
German: Langohr-Kreischeule

Taxonomy. *Scops sanctae-catarinae* Salvin, 1897, southern Brazil.

Perhaps a member of a superspecies, along with *O. guatemalae*, *O. vermiculatus*, *O. hoyi* and *O. atricapillus*. Formerly considered conspecific with *O. atricapillus*, but vocally and morphologically distinct, and treatment as separate species further supported by DNA evidence. Taxonomy of *Otus* in S Brazil and Argentine province of Misiones remains to be clarified. Monotypic.

Distribution. SE Brazil (Paraná, Santa Catarina, Rio Grande do Sul), NE Argentina (Misiones) and Uruguay.

Descriptive notes. 24-27 cm; male 155-194 g, female 174-211 g. Large *Otus*, with heavy body and strong feet. Occurs in brown and rufous morphs. Resembles *O. atricapillus*; differs in larger size and bulkier build, long and wider ear-tufts, lighter-coloured crown, usually less distinct streaking, yellow eyes (rarely light brown), much stronger feet and talons. Juvenile undescribed. **Voice.** Male primary song a fast trill, c. 13-14 notes per second, similar to *O. guatemalae* but louder, lower and slower, and may slightly ascend or descend or move to rougher notes, lasts 6-10 seconds, ends suddenly;

female version shorter, higher; male secondary song short fast notes that become longer and more spaced, in reversed bouncing-ball rhythm, phrase c. 5 seconds; female secondary song loud, hoarse, extraordinary, "bababa...", unlike any other screech-owl.

Habitat. Semi-open woodland, wooded pasture, upland moors with patches of *Araucaria*, and forest edge and secondary growth; locally, trees and copses in and near villages and agricultural areas; avoids dense forest. Found mainly at 300-1000 m.

Food and Feeding. Insects and small vertebrates. Reported as a sit-and-wait hunter, dropping from perch on to prey.

Breeding. Season apparently from late Aug/Sept; nest in tree cavity; no other information.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. Common in forested parts of Rio Grande do Sul and Santa Catarina; formerly locally common in N Misiones, in NE Argentina, but appears to have declined. Generally overlooked, especially as a result of confusion with *O. atricapillus*. Loss of habitat through overgrazing, burning and tree-felling represents greatest threat to species.

Bibliography. Belton (1984), Chebez (1994), Heidrich *et al.* (1995b), Hekstra (1982a), König (1991a, 1994b), Olog (1968, 1984, 1985), de la Peña (1994), Sick (1993, 1997), Stotz *et al.* (1996).

62. Puerto Rican Screech-owl

Otus nudipes

French: Petit-duc de Porto Rico **German:** Nacktfußeule **Spanish:** Autillo Portorriqueño
Other common names: Puerto Rican Bare-legged Owl; Virgin Islands Screech-owl, Newton's Owl (*newtoni*)

Taxonomy. *Strix nudipes* Daudin, 1800, Puerto Rico.

Earlier suggestion that it may form superspecies with Cuban *Gymnoglaux lawrencii* considered unacceptable; latter separated at generic level by very different morphology and vocal patterns. Validity of race *newtoni* has been disputed, possibly only a morph. Two subspecies recognized.

Subspecies and Distribution.

O. n. nudipes (Daudin, 1800) - Puerto Rico.

O. n. newtoni (Lawrence, 1860) - Vieques 1 off E Puerto Rico (1 record, probably extinct), and unconfirmed report from nearby Culebra I; also Virgin Is (St Thomas, St John, Tortola, Virgin Gorda, St Croix, probably Guana I).

Descriptive notes. 23-25 cm; c. 100-150 g. Medium-sized, with markedly rounded head lacking ear-tufts. Occurs in brown and rufous morphs. Facial disc rather dark, with whitish eyebrows, lores and chin, and faint dark border; upperparts with light spots and irregular narrow dark bars, scapulars with variable white on outer webs; wings and tail barred; underparts paler, with numerous darker vermiculations and shaft streaks, becoming whitish and less patterned on belly; upper tarsus feathered, lower bare; iris orange-brown; bill greenish-yellow; lower tarsus and toes yellow. Rufous morph less patterned. Juvenile nearly uniform

olive-brown above, head and neck lighter brown, underparts distinctly barred dusky brown and pale fulvous. Race *newtoni* rufous-tinged, less patterned below. **Voice.** Primary song short, deep trill c. 3-5 seconds long; secondary song shorter, 2 seconds, slight rise in middle, then dropping and fading out; female higher-pitched; also cackling and cooing calls.

Habitat. Forest and woodland of all types; coffee plantations, isolated coastal thickets, also small thickets and groves of large trees in urban areas; roosts in caves, trees and dense foliage by day. Sea-level to 900 m.

Food and Feeding. Mainly insects, such as grasshoppers and crickets; occasional small vertebrates. Emerges at night to hunt.

Breeding. Season Apr-Jun. Nest in tree cavity or cave, sometimes in cliff crevice. Usually 2 eggs (1-4); incubation by female; chick with whitish down.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Puerto Rico and the Virgin Islands EBA. Common in Puerto Rico, with no immediate threats obvious. Race *newtoni* extremely rare, possibly extinct: only 1 report ever from Vieques, considered possibly unreliable; no proof that species ever existed on Culebra; on St Croix, no verified records since 19th century; on St Thomas and St John, no definite 20th-century records, although unverified sightings by residents reported from St Thomas; despite historical reports from Guana, Tortola and Virgin Gorda, no verified records traced for any of those islands; some claims of this species known to have referred to misidentified *Asio flammeus*. In survey of Virgin Is in 1995, using playback of song recordings, no owls heard or seen. Race *newtoni* seems always to have been rather rare; destruction of forest for plantation crops, mainly since middle of 19th century, no doubt hastened its decline.

Bibliography. Anon. (1998a), Biaggi (1983), Bond (1985), Clark & Mikkola (1989), Gannon *et al.* (1993), Gundlach (1873), King (1978/79), Leck (1975), Lembeke (1850), Moreno (1998), Nellis (1979), Pardieck *et al.* (1992, 1996), Raffaele (1989), Raffaele *et al.* (1998), Rivera-Milan (1995), Stattersfield *et al.* (1998), Stotz *et al.* (1996), van der Weyden (1974), Wiley (1985, 1986a, 1986b).

63. White-throated Screech-owl

Otus albugularis

French: Petit-duc à gorge blanche **German:** Weißkehleule **Spanish:** Autillo Gorgiblanco

Taxonomy. *Syrnium albugularis*, Cassin, 1849, Choachi, Bogotá.

Sometimes placed in monotypic genus *Macabura*, or that name used as subgenus, on basis of lack of erectile ear-tufts. Vocal patterns, however, show close relationship with New World *Otus*. Races *obscurus* and *aequatorialis* possibly only morphs, or result of individual variation. Six subspecies recognized.

Subspecies and Distribution.

O. a. obscurus Phelps & Phelps, Jr., 1953 - Sierra de Perijá, in NW Venezuela.

O. a. meridensis (Chapman, 1923) - Andes of W Venezuela.

O. a. macabrum (Bonaparte, 1850) - C & W Andes from Colombia and Ecuador S to N Peru.

O. a. albogularis (Cassin, 1849) - E Andes of Colombia and N Ecuador.

O. a. aequatorialis (Chapman, 1922) - E Ecuador.

O. a. remotus Bond & Meyer de Schauensee, 1941 - E Andes from Peru S to C Bolivia (Cochabamba).

greyish; toes pinkish-grey. Juvenile pale buffy-grey, with orbital discs and long bristles above bill forming black mask, barred crown, mantle and underparts; on fledging resemble adult, but pattern more obscure. Race *meridensis* with whitish forehead and eyebrows, numerous pale freckles on upperparts suggesting nuchal collar; other races darker; *remotus* darkest, blackish above with few white and rufous spots, dark breast contrasting with poorly marked lower underparts. Voice. Male song 7-30 gruff, barked notes, "churrochurro-churro-chu chu chu chu", can be given uninterruptedly for 1 minute, possibly primary song; also evenly spaced hoots, c. 5 per second, gradually dropping, also reported as descending trill of 10-14 hoots every 5-10 seconds, probably secondary song; often, both sexes sing in more or less synchronized duet, female slightly higher-pitched; also gives single hoots.

Habitat. Humid montane evergreen forest, especially stunted alpine forest; mostly open forest and edge, and semi-open areas with scattered trees; habitat often rich in epiphytes and bamboo thickets, sometimes with glades or at least gaps in canopy. Occurs mostly at 2000-3000 m, but locally down to 1300 m.

Food and Feeding. Poorly known. Mainly insects; some small vertebrates. Nocturnal; forages in canopy.

Breeding. Female with enlarged ovary in Jul in Peru; nestlings in Oct in Ecuador; juveniles in Jan in Ecuador, Mar in C Peru, Sept in Venezuela. Nest possibly on ground in ferns and grass; or in old nest of other bird in tree or bush, e.g. incubated egg found in deserted cup nest above ground; probably also in natural holes when available. No other information.

Movements. Probably resident; likely to make seasonal altitudinal movements.

Status and Conservation. Not globally threatened. CITES II. Poorly known, but perhaps often overlooked; probably common; in surveys within known range, seen or heard in small numbers (fewer than 10 individuals) on daily basis. Has been recorded recently in Páramo de Tamá (Venezuela), at Río Blanco (Colombia), and along Baeza-Tena road (Ecuador) and Cuzco-Manu road (Peru). Conservation priority considered low to medium.

Genus *PYROGLAUX* Yamashina, 1938

64. Palau Owl

Pyrroglaux podarginus

French: Petit-duc des Palau

German: Palauleule

Spanish: Autillo de las Palau

Other common names: Palau Scops-owl

Taxonomy. *Noctua podargina* Hartlaub and Finsch, 1872, Palau Islands.

Often placed in *Otus*, but appears to be more distantly related to that genus. Monotypic.

Distribution. Palau Is (Babelthup, Koror, Peleliu and Angaur).

joins in duet, with lower, mellower song. The calls are not dissimilar to notes uttered by the Palau Fruit-dove (*Ptilinopus felewensis*), which can also be heard at night.

Habitat. All types of forest; frequently found in middle and upper levels of woodland trees and lagoon trees; often in deep ravines, and mangrove swamps; also steep forested ridges; noted near villages.

Food and Feeding. Large orthopterans and centipedes, arthropods and earthworms.

Breeding. Lays Feb-Mar. Territorial, in pairs and family groups throughout year; territory 100-200 m in diameter; nest in hollow tree. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Palau EBA. Current status uncertain. Formerly said to be abundant throughout its tiny range, with territories very densely spaced; in mid 1940's, 33 pairs found on Koror and 4 on Peleliu; has apparently declined since then. Further field research required to determine present population level.

Bibliography. Baker (1951), Clark & Mikkola (1989), Engbring (1988), Marshall (1949), Mayr (1945), Pratt, Bruner & Berrett (1987), Pratt, Engbring *et al.* (1980), Stattersfield *et al.* (1998).

Descriptive notes. 22 cm. Dark reddish-brown owl with large, rounded head without ear-tufts; facial disc only marginally paler, with whitish lores and eyebrows; upperparts with few light streaks, scapulars with black-tipped white spots; lighter below, with some pale barring and spotting; tarsus bare; iris brown; bill white; legs and feet whitish. Juvenile barred on crown, back and underparts. Voice. Male song a long series of low, mellow "whok" notes which rise in intensity and pitch to a sharp, whistled "quirt-quirt" or "wut-who", latter repeated at 2-second intervals in flight, faster with increasing excitement; female commonly

Genus *GYMNOGLAUX* Cabanis, 1855

65. Cuban Screech-owl

Gymnoglaux lawrencii

French: Petit-duc de Cuba

German: Kubaeule

Spanish: Autillo Cubano

Other common names: Bare-legged Owl/Screech-owl

Taxonomy. *Gymnoglaux lawrencii* P. L. Sclater and Salvin, 1868, Remedios, Cuba.

Often placed in *Otus*. Earlier suggestion that it may form superspecies with Puerto Rican *Otus nudipes* considered unacceptable; separated from latter at generic level by very different morphology and vocal patterns. Possibly related to *Athene*. Race *exsul* often not recognized. Two subspecies recognized.

Subspecies and Distribution.

G. l. exsul (Bangs, 1913) - W Cuba and I of Pines.

G. l. lawrencii P. L. Sclater & Salvin, 1868 - C & E Cuba.

Descriptive notes. 20-23 cm. Rather small, with large head lacking ear-tufts. Facial disc creamy-white with broad dark rim, long white eyebrows; upperparts brown, occasionally rufous-brown, spotted with white and black; wings barred; relatively long tail with only 10 feathers; creamy below, washed buff on breast, with dark shaft streaks; tarsus bare; iris brown; bill yellowish-grey; legs and feet yellow. Rather like *Athene cunicularia*, but underparts whiter, streaked. Juvenile sienna above and on breast, shading to lighter on belly. Race *exsul* very like nominate.

VOICE. Male song a low, accelerating "cu-cu-cu-cucuk" in bouncing-ball rhythm, rising slightly at end, also repeated "cu co, cu co, cu co..."; female utters harsh shriek, "hui hui hui hui ...".

Habitat. Wooded areas, mixed forest of palm, tropical semi-deciduous forest, and thickets; also large plantations.

Food and Feeding. Mainly large insects, but also frogs, snakes and, rarely, birds.

Breeding. Season Jan-Jun. Nest in tree cavity, including old woodpecker holes, sometimes in cave or sheltered cliff crevice. 2 eggs; chick with whitish down. Record of pair living more than 7 years in same area.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Considered fairly common or common, and widely distributed; rare on Cayo Romano and Cayo Coco, and probably also on Guajaba and on Sabinal Peninsula. Not well known, however, and more information needed on species' ecology and exact status.

Bibliography. Anon. (1998a), Barbour (1943), Bond (1985), Criado *et al.* (1995), Jiménez (1997), Raffaele *et al.* (1998), Stotz *et al.* (1996), Sulley & Sulley (1992), Wotzkow (1990).

Genus *PTILOPSIS* Kaup, 1851

66. Northern White-faced Owl

Ptilopsis leucotis

French: Petit-duc à face blanche de Temminck

German: Nordbüscheleule

Spanish: Autillo Cariblanco Norteño

Other common names: White-faced Scops-owl/Owl (with *P. granti*)

Taxonomy. *Strix leucotis* Temminck, 1820, Senegal.

Genus until recently merged with *Otus*, but shown by molecular-biological studies to be very different, and eyes also much bigger. Often treated as conspecific with *P. granti*; significant differences in DNA and vocal patterns, however, indicate that N and S populations specifically distinct. Pale birds in Sudan and dark ones elsewhere have been treated as racially distinct (as *margarethae* and *nigrovertex*, respectively), but both considered merely colour morphs. Monotypic.

Distribution. Senegambia E to Somalia, S to N Zaire, N Uganda and C Kenya.

Descriptive notes. c. 25 cm; wingspan 50 cm. Facial disc off-white, outlined in black; crown and nape light grey with dark grey vermiculations; long ear-tufts edged in black; upperparts pale grey to grey-brown, faintly vermiculated, with darker grey streaks, contrasting white scapular line; flight-feathers and tail grey-brown, barred with light grey; greyish-white below, with thin dark grey streaks and fine vermiculations; iris deep yellow to orange; bill creamy-horn; toes greyish. Dark morph darker, with brownish tinge, crown almost black; rare light morph very pale. Distinguished from *P. granti* by paler upperparts, yellow eyes. Ju-

venile paler and browner, head and breast not so heavily marked, facial disc pale grey, eyes yellow; also no ear-tufts and shorter tail. Voice. Mellow "po proo", repeated at intervals of 4-8 seconds; also low "ta-wit-ta-weet" in contact.

Habitat. Savanna and dry woodland with sparse ground cover, semi-desert with scattered thorn trees and wooded desert watercourses, to dense woodland with closed canopy; also forest edge and clearings; often near settlements, even in suburban gardens and towns in W. From sea-level to 1700 m.

Food and Feeding. Small mammals; also some birds, and insects including moths, beetles, spiders and scorpions. At 1 nest, 85% of prey small mammals, 10% arthropods, 5% birds. Requires c. 25 g

food/day. Nocturnal and crepuscular hunter. Hunts from perch, including telegraph wires, and drops on to prey by flapping and gliding low over ground; sometimes hunts around street lights; swallows prey whole, rarely plucking larger birds.

Breeding. Lays Jan-Sept; in Ghana said to breed Oct-Jan. Monogamous; solitary, but sometimes several pairs within 200 m of each other, and larger clutches, when food abundant. Nest small to large stick platform of other bird, such as pigeon (Columbidae), turaco (*Tauraco*), eagle or hawk (Accipitridae) or heron (Ardeidae), sometimes cavity or crevice in tree, usually 2-8 m above ground. 2-3 (1-4) eggs; incubation from first egg, by female, occasionally by male briefly, period c. 30 days; chick with whitish down; young brooded by female, male delivers food; young climb around outside nest at c. 27 days, can fly well at 30-32 days, remain with parents for at least 2 more weeks.

Movements. Resident; possibly some short-distance movements depending on rains and prey abundance.

Status and Conservation. Not globally threatened. CITES II. Locally common to uncommon throughout its range; less common and more local in E of range; rare resident in Somalia, only 11 confirmed records. Occurs in a number of protected areas throughout its range, such as Abuko Nature Reserve in Gambia, W National Park in Niger, Ouadi Rimé Reserve in Chad and Bamingui-Bangoran and Manovo-Gounda-Saint Floris National Parks in Central African Republic.

Bibliography. Ash & Miskell (1983b, 1998), Bannerman (1953), Barlow *et al.* (1997), Britton (1980), Cave & Macdonald (1955), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Field (1998), Fry *et al.* (1988), Gatter (1997), Giraudoux *et al.* (1988), Gore (1990), Grimes (1987), Kemp & Kemp (1998), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957, 1970), Marshall, I. (1997), Short *et al.* (1990), Snow, D.W. (1978, 1979), Steyn (1984), Zimmerman, D.A. *et al.* (1996).

67. Southern White-faced Owl

Ptilopsis granti

French: Petit-duc de Grant **German:** Südbütscheule **Spanish:** Autillo Cariblanco Sureño
Other common names: White-faced Scops-owl/Owl (with *P. leucotis*)

Taxonomy. *Pisorhina leucotis granti* Kolliway, 1910, Namibia.

Genus until recently merged with *Otus*, but shown by molecular-biological studies to be very different, and eyes also much bigger. Often treated as conspecific with *P. leucotis*, but differs significantly in DNA and vocal patterns. Monotypic.

Distribution. SE Gabon, C Congo, S Zaire, S Uganda and SW Kenya, S to S Namibia, N Cape Province and Natal.

Descriptive notes. c. 22-24 cm; male 185-220 g, female 125-275 g. Differs from *P. leucotis* in darker and greyer coloration, bolder black markings with more contrasting white face, orange-red to red eyes, stronger talons. Juvenile with shorter ear-tufts, more obscure markings, yellow eyes. **Voice.** Bubbling "popopopo-popeeu", first part in fast stutter, second more fluting and rising in pitch.

Habitat. Savanna with scattered trees, thornveld, dry open woodland, woodland along rivers, and forest edge and clearings.

Food and Feeding. Large insects, spiders, scorpions; also small vertebrates, including

mammals, birds and reptiles; recorded taking some relatively large prey, up to size of bush squirrel (*Paraxerus*) and dove (*Streptopelia*). Foraging behaviour as for *P. leucotis*; large prey held in talons and torn apart with bill.

Breeding. Lays mainly May-Nov, with local dry-season peak in Jul-Aug. Nest in hole in tree trunk or branch, or in old stick nest of larger bird; at Zimbabwe one territory occupied 12 years; not specified if it was the same pair. 2-3 eggs; incubation from first egg, by female, period c. 30 days; chick with white down; young begin to leave nest at c. 27-28 days, can fly well at 30-32 days, cared for by parents for at least 2 more weeks. In Zimbabwe, 14 young fledged at 1 site over 6 years.

Movements. Generally resident. In drier parts of range fairly nomadic, making movements resulting in local irruptions; arrives after rains or when food abundant, may stay for only a few weeks and disappear again; attracted to grass fires, sometimes flying fairly long distances to capitalize on flushed insects and rodents.

Status and Conservation. Not globally threatened. CITES II. Reasonably common in most of range; scarce in Kenya, rare in N Tanzania, and probably rare generally at N limits of distribution. Occurs in a number of protected areas throughout its range, such as Lilongwe Nature Sanctuary in Malawi, Hwange (Wankie), Victoria Falls, Gona-re-Zhou and Rhodes Matopos National Parks in Zimbabwe, Moremi National Park in Botswana, Etosha National Park in Namibia, Gorongosa Reserve in Mozambique, and Kalahari Gemsbok and Kruger National Parks in South Africa.

Bibliography. Genus *MIMIZUKU* Hachisuka, 1934

68. Giant Scops-owl

Mimizuku gurneyi

French: Petit-duc de Gurney **German:** Rotohreule **Spanish:** Búho de Mindanao
Other common names: Lesser/Mindanao Eagle-owl

Taxonomy. *Pseudopteryx gurneyi* Tweeddale, 1879, Zamboanga, Mindanao.

Formerly placed in an expanded *Otus*, but much larger than any of that genus, and distinct morphologically. Nevertheless, DNA studies indicate that it is closer to *Otus* than to *Bubo*; placement in a monotypic genus more appropriate pending further research. Monotypic.

Distribution. S Philippines: Dinagat, Siargao and Mindanao; report of former presence on Marinduque not confirmed.

Descriptive notes. 30 cm. Medium-sized owl, with long, well-developed, rufous ear-tufts marked with white; facial disc pale rufous, thinly outlined in black, with broad white eye-brows; dark rufous above with broad black shaft streaks, scapulars edged buffish-white; underparts white, washed rufous-buff on breast, and boldly streaked or spotted with dark brown; tarsi feathered white to toes; iris warm brown; bill yellowish to greyish; toes light grey. Juvenile undescribed. **Voice.** Has been recorded several times in recent years, but not description yet published.

Habitat. Lowland humid forest and secondary growth, from sea-level to c. 1200 m; recently reported from higher elevations, up to 3000 m.

Food and Feeding. No information.

Breeding. On Mt Katanglad, Mindanao, birds were vocally active in Feb. No other information.

Movements. Resident.

Status and Conservation. **ENDANGERED.** CITES I. Restricted-range species: present in Mindanao and the Eastern Visayas EBA. Appears to be rare in most of range, and thought to be a species that occurs at naturally low densities. Rapidly declining as a result of habitat destruction. May not be so rare as believed: on Mindanao, at 900-1200 m, call playback elicited responses from several individuals; postulated that, although many sympatric species are seriously threatened by forest clearance, most montane species may not yet be in extreme danger. Recent sightings from Mt Apo and Mt Katanglad, at higher altitudes, where adequate habitat still remains. Possibility that it occurs on other islands nearby where suitable habitat exists requires investigation.

Genus *BUBO* Duméril, 1806

69. Great Horned Owl

Bubo virginianus

French: Grand-duc d'Amérique German: Virginiauhu Spanish: Búho Americano

Taxonomy. *Strix virginiana* J. F. Gmelin, 1788, Virginia.

Has sometimes been considered to belong to the *B. bubo* superspecies. Formerly included *B. magellanicus* as a race, but DNA, voice and morphology found to differ. Numerous geographical races named, many poorly differentiated, or apparently result of individual variation, or due to wandering birds from other parts of range: thus, forms described from coastal W Alaska (*algestus*), C Canada (*scalariventris*), Venezuela (*scotinus*), E Colombia (*elutus*), C Colombia (*colombianus*) and E Brazil (*deserti*) considered not acceptable; also, name *occidentalis* used for birds from Rocky Mts of WC Canada to WC USA, but now synonymized with *subarcticus*; older name *wapacuthu* formerly applied to populations of W & C Canada and N USA (limits uncertain), but validity questioned; in addition, N populations *lagophonus* and *heterocnemis* possibly not separable from *saturatus*, perhaps better merged with latter; boundaries of races often obscure, and problem further complicated by birds of intermediate appearance; races *pacificus* and *pallidus* intergrade in California. Pending further study, twelve races tentatively recognized.

Subspecies and Distribution.

B. v. lagophonus (Oberholser, 1904) - Alaska, S in mountains to NE Oregon and NW Montana; in winter S to Texas.
B. v. saturatus Ridgway, 1877 - coast from SE Alaska to N California.
B. v. pacificus Cassin, 1854 - coast of California (except N) S to NW Baja California.
B. v. elachistus Brewster, 1902 - S Baja California.
B. v. subarcticus Hoy, 1853 - Mackenzie and NW British Columbia E to Hudson Bay, S at least to Wyoming and North Dakota; possibly this race, or intermediates between it and *pallidus* and/or *lagophonus*, or unnamed race, S to Arizona, New Mexico and SW Texas (Guadalupe Mts).
B. v. pallidus Stone, 1897 - C California (San Joaquin Valley) and deserts of SE California E to W Kansas, S to Mexico (S to Guerrero, W Veracruz).
B. v. heterocnemis (Oberholser, 1904) - NE Canada S to Great Lakes region.
B. v. virginianus (J. F. Gmelin, 1788) - Minnesota E to Nova Scotia and Prince Edward I, S through E Kansas and E Texas to Florida.
B. v. mayensis Nelson, 1901 - Yucatán Peninsula.
B. v. mesembrinus (Oberholser, 1904) - from Isthmus of Tehuantepec to W Panama.
B. v. nigrescens Berlepsch, 1884 - Andes from Colombia to NW Peru.
B. v. nacurutu (Vieillot, 1817) - lowlands from E Colombia to the Guianas; also Bolivia across to NE Brazil, S to EC Argentina (Buenos Aires).

Descriptive notes. Male 51 cm, wingspan 134 cm, 680-1450 g; female 60 cm, wingspan 143 cm, 1000-2500 g. Large, powerful owl, ear-tufts large and erect, plumage distinctly greyish to grey-brown or more buffy-brown, mottled and vermiculated above, barred below, with white throat; wings long and broad, pointed towards tip. Nominally *virginianus* with facial disc dull tawny-buff to distinct orange-buff, whitening around eyes, black rim broken by grey-buff flecking at lower edge; crown and hindneck dark; upperparts brownish with rufous tinge, mottled dark sooty-brown, broken by transverse mottlings of tawny grey-white.

wing-coverts and scapulars mottled with buff- to grey-white; flight-feathers and tail distinctly and regularly barred dark slate-grey to brown-black; underparts usually slightly sooty grey-buff with bold and somewhat erratic barring of brown-black, bars more pronounced on flanks and lower belly, and broad area of pure white on throat narrowing to upper breast; tarsus and feet fully feathered tawny to buff, often with black barring; iris brilliant yellow; bill grey; talons brownish yellow-horn, darkening to black at tip. Juvenile somewhat more ruddy brown-orange, bars farther apart, white throat patch duller and much less extensive, ear-tufts shorter. Races vary in size, tending to become smaller from NE to SW, small in S of range, and tend to be darker in more humid regions: *lagophonus* rich tawny-grey, feet barred; *saturatus* dark brownish-grey, heavily barred below; *pacificus* fairly dark, suffused tawny, less heavily barred, *elachistus* similar but much smaller; *subarcticus* pale whitish-buff, variably barred below, feet more or less plain; *pallidus* small, pale, barring above and below relatively indistinct, feet whitish; *heterocnemis* dark grey-brown, heavily barred below, feet mottled; *mayensis* small, short-winged, rather pale, *mesembrinus* similar but larger and darker; *nigrescens* dark, heavily blotched; *nacurutu* browner, longer-billed. **VOICE.** Male during courtship utters "hu-huooooo, hooh hooh" of c. 3 seconds; female higher-pitched with extra note at beginning, "hu-huuhoo hooh hooh"; also loud screams.

Habitat. Wide range of wooded habitats, mainly open, from deciduous to mixed and coniferous forest, second growth, swamp-forest, farmland with patches of woodland, larger parks in towns, and mangroves; generally with open fields adjacent or nearby; also roadsides; locally, desert and rocky areas with some woodland. Foraging areas typically relatively open, but also include some woodland or groves, or at least scattered trees for perching. Sea-level to c. 4000 m; in Andes to 4500 m.

Food and Feeding. Very diverse range of prey includes small mammals, birds, amphibians, reptiles, fish, and insects and other invertebrates; sometimes takes carrion when weather conditions severe. Mammals generally most important, often c. 90% of diet; lagomorphs, mice and waterbirds major food in many areas. Birds average c. 10% of food, range in size from small passerines up to geese and Great Blue Heron (*Ardea herodias*), and include other raptors; also nestlings. In N Canada, snowshoe hares (*Lepus*) represent 83-86% to 13% of diet, depending on hare density; alternative

prey mainly voles (*Microtus*), ground squirrels (*Spermophilus*) and birds. In Argentina, mammals also majority of prey (69%); arthropods an alternative, with beetles (21%) and scorpionids (5%) most common, and birds, reptiles and amphibians poorly represented. Forages mostly at dusk and during night, rarely in daylight, usually in fairly open areas offering wide view, e.g. forest edge or clearings, or along wetland margins, also over open water. Hunts from perch, dropping steeply to ground and levelling off just above it; also flaps and glides over places where prey likely to be; occasionally forages by walking on ground, and reported to wade into water. Prey seized in talons; smaller items swallowed whole, larger ones dismembered first.

Breeding. Season approximately Dec-Jul; female observed to incubate in sub-zero temperatures, with 30-cm snow cover on ground. Normally uses old nest of other large bird such as corvid or raptor, in N often Red-tailed Hawk (*Buteo jamaicensis*), high up in main fork of tree, sometimes in heronry; also hollow at broken-off snag, or man-made platform, or depression on cliff ledge or ground, or cave entrance (in Ohio study, 533 in hawk nest, 527 in snag, 125 on man-made platform); rarely on building, once on beam beneath railway bridge; no material added; may use same nest 2-3 years in succession. In courtship display, both sexes hoot while bowing and while simultaneously drooping wings and cocking tail. 1-3 eggs, usually 2, up to 6 in food-rich years, laying interval averaging 72 hours; clutch often replaced if first destroyed; incubation c. 28-30 days, sometimes up to 37, by female, fed regularly through night by male; rarely, latter recorded incubating briefly; chick with white down, pink apteria and feet; young brooded by female until c. 2 weeks, climb on nearby branches at 6-7 weeks, fly well from c. 10 weeks; subsequent parental care up to 5 months. In USA (Ohio), mean annual productivity 1.7 young per successful nest, 1.3 young per breeding attempt, 15% of breeding pairs failed, 38% of pairs did not attempt to nest, average 0.80 young per occupied territory; in one study, mortality highest during post-fledging period, with 13 deaths due to high levels of parasitism, 11 to predation (or with signs of scavenging), 9 to disease, starvation or cause unknown, 6 roadkills; survival in first 2 years of life low, but higher during peaks in hare cycle. First breeding probably at 2 years, sometimes 1. Maximum recorded longevity more than 28 years.

Movements. Mostly resident, but some movement by N birds. In Canada (Saskatchewan), substantial SE movement in Nov-Dec in some years, with 17 of 35 recoveries occurring beyond 250 km from point of ringing; evidently, moves farther S during years of decreased reproductive success and, presumably, reduced food supplies.

Status and Conservation. Not globally threatened. CITES II. Widespread, but densities low; few population estimates. Commonest owl in S Quebec; in optimum habitat in North America, densities of 0.1-0.2 pairs/km², in S of range rather scarce generally, but said to be quite common in S Mato Grosso in Brazil. Population levels closely associated with prey availability: when prey scarce, breeding density much lower and mortality sometimes very high; in periods of high prey abundance, higher survival leads to greater intraspecific (and interspecific) competition. Heavily persecuted in first half of 20th century, but totally protected in North America since 1970; probably reasonably stable now within limits of annual fluctuations. In Canada, however, presence of individuals referred to as "non-territorial floaters" (a "shadow" population that lives a secretive life, moves more often than territorial birds, and ranges broadly over territories of latter) can delay detection of population declines in traditional censuses. Roadkills, pesticides, collisions with man-made objects, electrocution from power lines, and indiscriminate and illegal shooting are major causes of mortality locally in USA (Utah); these factors likely to be applicable elsewhere in range. Habitat disruption apparently less of a threat, and range and numbers noted to have expanded in Pacific Northwest following opening-up of new areas by logging activities. Species' continuing survival almost throughout range aided perhaps by its highly secretive nature and its high capacity for ecological adaptability; adapts well to changes in habitat, so long as suitable nest-sites and roost-sites remain.

70. Magellanic Horned Owl

Bubo magellanicus

French: Grand-duc de Magellanie German: Magellanuhu Spanish: Búho Magallánico
Other common names: Magellan Great Horned Owl, Lesser Horned Owl

Taxonomy. (*Strix*) *magellanicus*, J. F. Gmelin, 1788, Straits of Magellan.

Until recently included as a race of *B. virginianus*, but differs in vocalizations and morphology, and also in DNA; in past, occasionally even merged with *B. v. nacurutu*. Monotypic.

Distribution. From C Peru, W Bolivia and W Argentina, S to Tierra del Fuego and Cape Horn.

Descriptive notes. c. 45 cm. Very like *B. virginianus*; differs in smaller size, smaller ear-tufts, smaller bill, weaker talons, more prominent rim around facial disc, narrower and more closely spaced barring below; general coloration varies from grey-brown to darker brown. Juvenile much as *B. virginianus*. **VOICE.** Male song 2 deep hoots, second one stressed, followed by low quiet purring sound, "huOOH-urrrr"; female gives longer purr; duets in courtship.

Habitat. Rocky upland pasture, semi-open forest (especially *Nothofagus*), Patagonian steppe and semi-desert with scattered trees, bushy ravines and surrounding grassland; in S, also parks in areas of human settlement. In Andes mostly at 2500-4500 m; locally down to sea-level.

Breeding. Season begins late winter. Nest in crevice or rock overhang; sometimes depression on ground in forest. 2-3 eggs; incubation by female, fed by male; young leave nest before able to fly, remain nearby.

Movements. Resident; some birds in extreme S move N in winter; juveniles sometimes wander longer distances.

Status and Conservation. Not globally threatened, CITES II. Seems to be common in Chile and Patagonia. Numbers in C Chile increased after introduction of rabbit (*Oryctolagus cuniculus*) in 1907. Main threat appears to be human persecution, which locally quite severe; poisoned baits for foxes in Patagonia may be a potential threat, although no known deaths from such causes reported; road casualties also quite frequent.

Bibliography. Canevari *et al.* (1991), Castro & Jaksin (1995), Fjeldså & Krabbe (1990), Humphrey *et al.* (1970), Friarte *et al.* (1990), Jaksic & Marti (1984), Jaksic & Yáñez (1980), Jaksic, Meserve *et al.* (1993), Jaksic, Rau & Yáñez (1978), Jaksic, Yáñez & Rau (1986), König *et al.* (1996), de la Peña (1994), Reisse & Venegas (1974), Stotz *et al.* (1996), Tala *et al.* (1995), Taylor (1958b).

71. Eurasian Eagle-owl

Bubo bubo

French: Grand-duc d'Europe **German:** Uhu **Spanish:** Búho Real
Other common names: Common/Great/Northern Eagle-owl

Taxonomy. *Strix Bubo* Linnaeus, 1758, Sweden.

Forms superspecies with *B. bengalensis* and *B. ascalaphus*, with *B. virginianus* (including recently separated *B. magellanicus*) and *B. capensis* sometimes considered part of same group. Sometimes considered to include first two as races; appears to intergrade with *B. ascalaphus* in parts of Middle East, suggesting that conspecificity perhaps not impossible. Geographical boundaries of races obscured throughout by intergrading populations. Large number of additional races named, some representing no more than individual variation or intermediates; e.g. populations described from Bashkirskaya (*bashkiricus*) included in *sibiricus*; from L Zaysan region (*zaisanensis*) in *yeniseensis*; from NW Xinjiang (*tarimensis*) in *turcomanus*; from C Tibet and NW China (*tibetanus*) in *hemachalana*; from N Mongolia (*dauricus*) and Sakhalin (*borissowi*) in *ussuriensis*; from SE Yunnan (*jarlandi*), Sichuan (*seichuanus*), Manchuria and N China (*inexpectatus*) in *kiautschensis*; and from S Kurils, Hokkaido and Korea (*tenuipes*) split between *ussuriensis* and *kiautschensis*. Fourteen subspecies recognized.

Subspecies and Distribution.

- B. b. hispanus* Rothschild & Hartert, 1910 - Iberian Peninsula; formerly also Atlas Mts in NW Africa (probably extinct).
- B. b. bubo* (Linnaeus, 1758) - Europe from N Spain and Scandinavia E to W Russia (E to about Gor'kiy).
- B. b. ruthenus* Buturlin & Zhitkov, 1906 - C European Russia E to foothills of Ural Mts, S to lower Volga basin.
- B. b. interpositus* Rothschild & Hartert, 1910 - from Romania and S Ukraine E to Volga delta, S to Middle East (S to C Israel and Jordan) and NW Iran.
- B. b. sibiricus* (Gloger, 1833) - from W foothills of Urals E to R Ob, S to W Altai.
- B. b. yeniseensis* Buturlin, 1911 - C Siberia from R Ob to L Baikal, S to Altai and N Mongolia.
- B. b. turcomanus* (Eversmann, 1835) - steppes between lower R Volga and R Ural, E to Transbaikalia, and S to Kazakhstan, extreme NW China (Tarim Basin in NW Xinjiang) and W Mongolia.
- B. b. omissus* Dementiev, 1932 - Turkmeniya to W China (Chinese Turkestan).
- B. b. hemachalana* Hume, 1873 - from Pamirs and N Tien Shan S to Himalayas.
- B. b. nikolskii* Zarudny, 1905 - E Iraq and Iran, Afghanistan, and N & W Pakistan.
- B. b. jakutensis* Buturlin, 1908 - NE Siberia.
- B. b. ussuriensis* Poljakov, 1915 - SE Siberia to NE China, Sakhalin, N Hokkaido and S Kuril Is.
- B. b. kiautschensis* Reichenow, 1903 - from W & C China (S to Yunnan and Sichuan) E to Korea.
- B. b. swinhoei* Hartert, 1913 - SE China.

on flanks and belly; tarsus and toes fully feathered buff-white; iris golden to orange; bill black. Juvenile with rudimentary ear-tufts, head with buffy down, underparts and wing- and tail-coverts narrowly barred. Races differ mainly in general coloration, strength of dark markings, and size: *hispanus* and *ruthenus* lighter and greyer than nominate; *interpositus* darker, more rufous; *sibiricus* very pale, creamy-white below with contrasting streaks; *yeniseensis* darker, with yellow ground colour; *hemachalana* more light brown above, including mantle, *turcomanus* similar but greyer; *omissus* with ochre ground colour, markings below less heavy, *nikolskii* smaller and more rufous; *jakutensis* dark, browner above, well marked below, *ussuriensis* darker still with ochre wash below; *kiautschensis* rather small, very dark, streaking thin; *swinhoei* small, strongly tinged rufous. Voice. Territorial call a booming "boo-ho" or "ooo-hu", first syllable emphasised, second lower,

Food and Feeding. Mostly small mammals up to size of rabbits and hares; also birds, reptiles and some invertebrates. A pellet analysis in C Chile revealed 69.3% rodents, 15.8% rabbits and 11.4% birds; in a study in S Chile, diet consisted solely of rodents, with *Auliscomys micropus* and *Abrothrix longipillus* together forming 60.4% of prey in terms of numbers captured and 74.4% of biomass consumed. Hunts mostly at dusk and dawn, sometimes nocturnally; also by day in S of range, where close to 24-hour daylight during summer. Foraging methods similar to those of *B. virginianus*; often uses rock as lookout perch.

repeated every 8-10 seconds; female higher-pitched, hoarser; duets in courtship; female also barking scream; alarm harsh "ka ka-kau".

Habitat. Tends to inhabit regions of sparse human settlement or areas of topographically inaccessible terrain: mainly rocky country with cliffs and ravines, caves, patches of woodland, scattered trees or groves, generally in undisturbed wilderness areas; also open forest, taiga and other types of woodland, wooded steppe, river valleys with gorges, overgrown quarries; also farmland with suitable rocky areas or cliffs. Forages also over open or sparsely wooded terrain, as well as floodland, heaths, farmed valley bottoms or levels with grassland, small arable fields, and even refuse dumps. Breeds from sea-level up to c. 2000 m in Europe; 4200-4500 m in C Asia and Himalayas.

Food and Feeding. Mostly mammals, from size of water vole (*Arvicola*) to adult hares (*Lepus*), and birds from size of jay (*Garrulus*) to herons (Ardeidae) and buzzard (*Buteo*); also occasionally amphibians, reptiles, fish, and invertebrates (especially beetles). Preferred prey size in range 200-2000 g. In C Europe lagomorphs important prey, also hedgehogs (*Erinaceus*) locally; in China, mainly rats and mice. Diet can vary according to prey abundance and season; in Sweden, rodents taken in proportion to their population levels, ranging from 23% to 65% in different years, and adult hares increase in importance in late winter, with other prey (e.g. fledgling birds) becoming important when available; in Finland, 1 pair's diet largely water voles when abundant, switched to brown rats (*Rattus norvegicus*) from nearby rubbish dump at other times; in Spain, proportion of birds in diet may increase in spring and summer, and shortage of rodents compensated for by increase in birds. Cannibalism occurs, with weakest young eaten by parents or siblings, and occasionally a full-grown bird recorded eaten by conspecifics. Primarily nocturnal, somewhat crepuscular, even diurnal in summer at N edge of range. Hunts mostly from open perch; also in searching flight; takes prey by surprise while flying close to ground or tree-tops; sometimes makes systematic searches of rock crevices for roosting birds; usually watches and waits for prey to reveal itself, but also recorded jumping around looking for Common Eiders (*Somateria*) on nest. Said also to take birds in full flight, to seize fish by plunging into water like Osprey (*Pandion haliaetus*), and to plunder both adults and young of nest of e.g. crows (*Corvus*) over 1-2 nights.

Breeding. Season Feb-Aug in Scandinavia; laying from Dec in France. Monogamous; solitary. Nest on sheltered cliff ledge or in crevice, in cave entrance, on ground on steep slope or on flatter ground in taiga, sometimes in old tree nest of other species, rarely in hole in tree; same site often used over several years, or favoured sites in territory used partly in rotation. 2-4 eggs, occasionally 1, laying interval 3 days; incubation 34-36 days, by female, fed by male; hatching asynchronous, chick with whitish and buffy down; young brooded by female, continuously for c. 15 days, male feeds female and young; after 3 weeks young start to feed themselves at nest, move outside nest at 5 weeks (earlier in case of ground nests), can fly at c. 7 weeks; young independent at 20-24 weeks. In Sweden, of 219 occupied territories, 66% had active nests, of which 60% produced fledged young, making total of 136 young produced, and averages of 1.6 young per successful nest, 0.9 per active nest and 0.6 per occupied territory; production varied according to food supply; losses attributed to starvation, predation, and human disturbance, including egg-collectors; extremely sensitive to disturbance, parents may abandon eggs and even small young. First breeding at 2-3 years. Oldest known age at least 21 years; up to 60 years reported in captivity.

Movements. Resident in most of range; juveniles disperse variable distances, recorded as vagrant in Nile valley. In N of range, some move S in winter, depending on food availability; in harsh winter conditions of N & C Asia, can be highly nomadic.

Status and Conservation. Not globally threatened, CITES II. Uncommon to scarce or rare throughout range. Total European population (including W Russia and Turkey) in mid 1990's estimated at c. 25,000 pairs, of which c. 50% in Russia. Densities low in most areas, with maximum 1 pair/100 km² in C Europe; higher in S France, where 43-50 pairs in study area of 200 km²; c. 6 pairs/100 km² in Spain, and in Finland 2-13 pairs/100 km². Considerable decline in Europe in 20th century, with extinctions in e.g. Luxembourg and Denmark, and reductions in range and population elsewhere; in Sweden, widespread until late 19th century but extinct in many areas by c. 1920. In general, decreases due mainly to human persecution; significant decline in Mediterranean countries in 1960's apparently due to effects of myxomatosis on rabbit population; in addition, poisoning from mercury seed-dressings, and deaths through road traffic and barbed wire not insignificant. Fairly rapid post-1970 recovery in parts of Europe aided by protection and by extensive reintroduction programmes, especially in Germany, France, Belgium, Switzerland and Scandinavia, although reintroduced birds suffer high mortality and poor breeding success; increased food supply created by proliferation of refuse tips (rats) or large clearfelled areas (various rodents and birds) probably also a factor in promoting recovery. Nevertheless, overall trend almost certainly one of decline. No detailed data on Asian populations, but uncommon or rare everywhere, and marked decline noted in many areas since 1970's. Despite protected status, species still persecuted locally; pesticides and other toxic chemicals also remain a problem in some areas. Protection of nesting territories, and potential territories, from development and from extensive logging recommended.

72. Rock Eagle-owl

Bubo bengalensis

French: Grand-duc indien **German:** Bengalenuhu **Spanish:** Búho Bengali
Other common names: Indian Eagle-owl/Great Horned Owl

Taxonomy. *Otus Bengalensis* Franklin, 1831, River Ganges between Calcutta and Varanasi and in Vindhyan Hills between Varanasi and Gurra Mundela.

Forms superspecies with *B. bubo* and *B. ascalaphus*, with *B. virginianus* (including recently separated *B. magellanicus*) and *B. capensis* sometimes considered part of same group. Sometimes treated as conspecific with *B. bubo*; degree of range overlap, if any, with latter uncertain, but they differ in DNA and voice. Monotypic.

Distribution. Indian Subcontinent (except Sri Lanka), N to foothills of Himalayas, and W Myanmar.

Descriptive notes. 56 cm; 1 male c. 1100 g. Large, dark brown owl with prominent ear-tufts. Resembles *B. bubo*; differs from race *hemachalana* of latter in smaller size, darker and more tawny-buff coloration with black mottling and streaking, somewhat less heavy streaking below; iris golden to orange-yellow or reddish; bill horn, greenish or slaty-black. Dark and light morphs, former having darker ground colour with fewer light spots above. Distinguished from *Ketupa zeylonensis* by fully feathered tarsi and toes, more erect ear-tufts, broader breast streaking, and plainly banded tail. Juvenile lacks ear-tufts, obscurely barred

on head, mantle and underparts. VOICE. Deep double hoot, with second note longer and stressed; female a little higher-pitched; also growls, hisses, coughs.

Habitat. Rocky hills and wooded country with scrub, ravines, old mango plantations, groves with aged trees, tropical thorn and sal, and rocky semi-desert with thorn scrub, ruins; sometimes near cultivation and villages; avoids pure desert, as well as humid evergreen forest. From lowlands up to 2400 m.

Food and Feeding. Small mammals, especially rodents; also birds to size of peafowl (*Pavo*), and lizards, snakes, frogs, fish and crabs; some insects, too. Largely nocturnal, but often perches on rock pinnacle or other vantage point well before sunset and after sunrise. Hunts by gliding from perch on to prey; sometimes makes searching flights.

Breeding. Lays Oct-May, chiefly Feb-Apr; peak periods vary locally. No nest; lays on bare soil in saucer-like scrape on rock ledge or recess in cliff; sometimes on ground under tree or bush. Usually 4 eggs (2-5); incubation from first egg, by female, period c. 35 days; young hatch asynchronously; chick with buffish-white down.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. No details on population levels; generally uncommon, but perhaps more common locally in N and C India. Further studies needed on ecology and biology.

Bibliography. Ali (1996), Ali & Ripley (1981), Beaman (1994), Dharmakumarsinhji (1939), Eates (1937, 1939), Grimmett *et al.* (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Mahabai & Lamba (1987), Majumdar *et al.* (1992), Mukherjee (1995), Ripley (1982), Simmons (1976), Smythies (1986), Thompson *et al.* (1993).

73. Pharaoh Eagle-owl

Bubo ascalaphus

French: Grand-duc du désert

German: Wüstenuhu

Spanish: Búho Desértico

Other common names: Desert/Savigny's Eagle-owl

Taxonomy. *Bubo Ascalaphus* Savigny, 1809, Upper Egypt.

Forms superspecies with *B. bubo* and *B. bengalensis*, with *B. virginianus* (including recently separated *B. magellanicus*) and *B. capensis* sometimes considered part of same group. Formerly treated as conspecific with *B. bubo*; separation based mainly on vocalizations, and partly morphology, but DNA evidence not conclusive; also, appears to intergrade with *B. bubo* in parts of Middle East, suggesting that conspecificity perhaps possible; on other hand, some range overlap without known intermediates with *B. bubo* race *hispanus* in NW Africa, although latter now presumed extinct there; further study warranted. Two subspecies recognized.

Subspecies and Distribution.

B. a. ascalaphus Savigny, 1809 - NW Africa and N Egypt E to W Iraq.

B. a. desertorum Erlanger, 1897 - Sahara S to Mauritania and Niger, E to Ethiopia, Arabia and S Iraq.

Descriptive notes. 46-50 cm; male c. 1900 g, female c. 2300 g. Facial disc light tawny-rufous with darker rim; tawny head and neck streaked with dark brown; upperparts tawny with black streaks and blotches, buffish mottling; flight-feathers less distinctly barred; conspicuous white throat patch; sandy-rufous below, chest with broad black streaks, lower breast to belly with very fine vermiculations; underwing almost white; tarsus fully feathered; iris yellow to orange; bill black. Distinguished from *B. bubo* by smaller size (c. 20% smaller), shorter ear-tufts, paler appearance, less streaked and more mottled; from *B. capensis* by paler

and less variegated plumage. Juvenile more barred than blotched on upperparts and breast, ear-tufts not fully developed. Race *desertorum* slightly smaller and paler, more sandy, with very pale underparts. VOICE. Single deep, downslurred "whu"; in courtship also 3-note hoot; voice slightly higher than *B. bubo*; quacking call in alarm.

Habitat. Rocky desert hills, wadis with cliffs, and open desert with rock outcrops; extends S into dry savanna in S. Roosts by day in rock cleft or crevice, occasionally in tree if present.

Food and Feeding. Small mammals, especially rodents, with gerbils (*Gerbillus*) favoured prey; also birds and reptiles, and some insects. Generally opportunist, taking any animal food available, including desert foxes, hares, bats and scorpions. Crepuscular or nocturnal; hunts from perch.

Breeding. Lays Feb-Mar. Monogamous; pairs for life. Nest a scrape in rock crevice, among rocks or on ground, sometimes down well (in darkness); sometimes old nest of large bird or tree hole in desertified areas of sub-Sahara: same territory maintained for many years. Usually 2 eggs, but up to 4; incubation by female, fed by male, period 31-36 days; chick with buffish-white down; young brooded and fed by female, male provides food; disperse from nest at 20-35 days, fully fledged at 52-70 days, independent by 20-26 weeks. First breeding at 2-3 years.

Movements. Resident; presumably some wandering by juveniles.

Status and Conservation. Not globally threatened. CITES II. Little information on population levels, but probably not uncommon in most of range. In S Israel, c. 50 pairs estimated in early 1990's. Possibly subject to human persecution locally.

Bibliography. Amr *et al.* (1997), Aspinall (1996), Bannerman (1953), Beaman (1994), Beaman & Madge (1998), Boukhamza *et al.* (1994), Carpentier (1934), Cave & Macdonald (1955), Cramp (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Échécopar & Hùe (1964), Evans (1994), Evans & Bates (1993), Fry *et al.* (1988), Giraudoux *et al.* (1988), Goodman *et al.* (1989), Hùe & Échécopar (1970), Jennings (1995), Kemp & Kemp (1998), Ledant *et al.* (1981), Lesne & Thevenot (1981), Mackworth-Præd & Grant (1957, 1970), Mendelsohn (1996), Paz (1987), Porter, Christensen & Schiermacker-Hansen (1996), Sellami & Belkacemi (1989), Sharland, R.E. (1981), Shirihai (1996), Snow (1978), Snow & Perrins (1998), Vein & Thevenot (1978), Voous (1988).

74. Cape Eagle-owl

Bubo capensis

French: Grand-duc du Cap

German: Kapuhu

Spanish: Búho de El Cabo

Other common names: Dillon's/Mountain Eagle-owl (*dillonii*); Mackinder's Eagle-owl (*mackinderi*)

Taxonomy. *Bubo Capensis* A. Smith, 1834, near Cape Town, South Africa.

Affinities uncertain. Formerly thought to be member of *B. bubo* superspecies, but seems more distantly related. Race *mackinderi* has been considered a full species, but differences minor. Three subspecies recognized.

Subspecies and Distribution.

B. c. dillonii Des Murs & Prévost, 1846 - S Eritrea and Ethiopian Highlands.

B. c. mackinderi Sharpe, 1899 - from WC Kenya S to Zimbabwe and W Mozambique.

B. c. capensis A. Smith, 1834 - South Africa and extreme S Namibia.

Descriptive notes. 48-58 cm; wingspan c. 120 cm; male 900-1400 g, female 1200-1800 g. Large, with long, pointed ear-tufts. Generally dark brown. Facial disc pale buff-brown with blackish border; dark brown above with light tawny and buff spotting, wing-coverts variably spotted white; flight-feathers and tail barred; throat white; underparts creamy buff-brown, breast with heavy dark blotching, flanks spotted and abdomen barred; tarsus and toes thickly feathered; iris orange to orange-yellow; bill dark greyish. Differs from *B. africanus* in larger size, orange eyes, browner plumage and breast markings. Juvenile largely grey with rufous

barring, wings and tail as adult; indistinct ear-tufts. Races separated by size: *mackinderi* largest, darker above; *dillonii* almost as big, darkest. VOICE. Deep hoot, "hoooo-ho", first note loud and second weak, also 3-note "hu-hoo-hu"; female higher-pitched; occasional duets.

Habitat. Wooded valleys, low cliffs and ravines, in rocky mountainous terrain from 2000 m to 4200 m; hunts also over adjacent open rocky slopes and grassland. In S. occurs also in flat, dry and open country.

Food and Feeding. Mid-sized mammals, mainly hares and hyraxes, but including bats, rats and mole-rats; also birds, especially pigeons and gamebirds, but up to size of Hamerkop (*Scopus umbretta*); occasionally reptiles and amphibians, scorpions and insects. Crepuscular and nocturnal. Hunts by surveying area from prominent perch, and descending upon prey in long glide; also engages in aerial chases.

Breeding. Lays Jul-Mar in E Africa, Jul in S Africa; in SW Cape in Jun-Aug, in E Cape Aug-Sept; irregular breeder, attempting every 10-11 months or 2-3 years, possibly depending on prey abundance. Nest an unlined scrape on sheltered cliff ledge, or in cave entrance, or beneath bush on ground; occasionally uses old stick nest of large bird; thick, enamel-like droppings on ledge often clue to active nest; large accumulations of bones from prey form ossuaries near nest. 1-3 eggs, usually 2; incubation 34-36 days, by female, fed by male; chick with whitish down; young brooded and fed by female, male delivers prey during night; young begin to wander outside nest at 45 days, can fly by 60-77 days (smaller nominate *capensis* fledging earliest), dependent on parents for at least 2-3 months after fledging. In Kenya 60% of eggs laid fledged young, in Zimbabwe 50%; cannibalism of younger siblings regular.

Movements. Generally resident; young birds may wander widely, occasionally occurring in cities and outside normal range.

Status and Conservation. Not globally threatened. CITES II. Generally uncommon to rare, and very local; more common in some places, e.g. Mau Plateau in SW Kenya, but easily overlooked and never at high densities. Most widespread in S Africa at low altitudes; to N, range more fragmented and confined to mountains. Predation of ground nests, along with road-traffic casualties, collisions with power lines and entanglement on barbed-wire fences, seem to be main threats; young reportedly taken by humans for pets, often die or left crippled through improper feeding.

Bibliography. Allan (1995), Benson & Benson (1977), Brooke (1973b), Burger (1980), Clinning (1980), Daugherty (1981), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Gamble (1979), Gargett (1976, 1977a, 1977b, 1978, 1983), Gargett & Grobler (1976), Ginn *et al.* (1989), Grobler (1980, 1982), Harrison *et al.* (1997), Hockey *et al.* (1989), Jackson (1973b), Kemp & Calburn (1987), Kemp & Kemp (1998), Lewis (1978), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957, 1962), Maclean (1993), Martin & Pepler (1977), Mathews & Scott (1980), Medland (1989), Pickford *et al.* (1989), Rossouw (1993), Rutledge (1986), Sessions (1972), Short *et al.* (1990), Snell (1979), Snow (1978), Steyn (1982, 1984, 1992, 1994c), Steyn & Tredgold (1977), Taylor (1987), Walter *et al.* (1986), Weiss & Weiss (1993a, 1993b), Zimmerman, D.A. *et al.* (1996).

75. Spotted Eagle-owl

Bubo africanus

French: Grand-duc africain

German: Fleckenuhu

Spanish: Búho Africano

Other common names: African Eagle-owl

Taxonomy. *Strix africana* Temminck, 1821, Cape of Good Hope, South Africa.

Often considered to include *B. cinerascens* as a race, but the two differ in morphology and not known to interbreed where ranges overlap. Taxonomic status of race *milesi* not well understood, possibly specifically distinct. Race *tanæae* perhaps only pale variant, as is form described from Namibia (*trothæ*). Three subspecies recognized.

Subspecies and Distribution.

B. a. milesi Sharpe, 1886 - SW Arabia, Yemen and Oman.

B. a. africanus (Temminck, 1821) - Gabon E to Zaire (S of rainforest), S Uganda and C Kenya, S to the Cape.

B. a. tanæae Keith & Twomey, 1968 - R Tana and Lali Hills, in SE Kenya.

Descriptive notes. c. 45 cm; wingspan c. 100 cm; male 490–620 g, female 640–850 g. Rather small eagle-owl with long, erect ear-tufts. Facial disc grey with faint white bars, outlined in black; head and neck brown-grey with white to buff spots, including ear-tufts; upperparts grey to brown with pale spots, flight-feathers and tail broadly banded in buff; whitish below, finely barred grey-brown, upper breast often with large grey blotches; tarsus feathered whitish, faintly barred; iris yellow; bill black. In more arid areas rarer chestnut-brown morph, with ground colour browner above and buff below, eyes orange. Differs from *B. capensis* in smaller size, yellow eyes, and greyer plumage. Juvenile waspish browner below, less spotted above. Race *milesi* smaller, more tawny; *tanai* paler, less barred. **VOICE.** Male gives "hoo-hoo", second note lower, followed by 3-note hoot plus longer note, also single notes or various combinations; female triple "hoo-whoohoo"; often duets, female following so closely that calls sound like one; loud "kiow" in alarm.

Habitat. Variety of habitats, from rocky outcrops in desert to woodland with sparse ground cover; particularly favours areas with mosaic of low hills, grassland and scrub; prefers semi-open woodland, and rocky hills with scattered trees and bushes; also found in thorn savanna; avoids dense forest. From sea-level up to c. 2100 m.

Food and Feeding. Opportunist, taking mainly arthropods, small mammals and birds. Large number of different types of prey recorded: arthropods include scorpions, spiders and beetles; mammals include moles, rodents, hedgehogs and bats; birds range from sunbirds and doves to falcons, hornbills and francolins; also reptiles, amphibians, snails, and freshwater crabs. Diet related to locality and season: in Namib Desert mainly geckos, gerbils and moles, but in South Africa 67% of 1076 prey items were invertebrates; along coast, a pair fed mostly on terns; rodents major prey when abundant. Occasionally eats carrion; regularly drinks water. Crepuscular and nocturnal, rarely diurnal. Hunts from perch, often along roadsides, gliding down on to prey; most prey taken on ground, where often runs after smaller animals; also chases insects, bats and birds aerially.

Breeding. Lays in Jul–Feb; mainly Jul–Oct in S Africa. Monogamous, probably pairs for life. Nest a shallow scrape, usually on ground beneath bush, among grass or rocks or on earth bank, but can be on cliff ledge, or on old platform built by Hamerkop (*Scopus umbretta*), or using Social Weaver (*Philetairus socius*) colony as platform; sometimes in hole in tree or building; same site sometimes used yearly, giving it distinctive odour; traditional sites may be occupied for 30–40 years. 2–4 (1–5) eggs; incubation 30–32 days, from first or second egg, by female, fed by male; chick with white down; young brooded and fed by female, male delivers prey usually decapitated; young leave nest at 30–38 days, later if nest above ground, fledge at c. 48 days, dependent on parents for at least 5 weeks after fledging, but exact age of independence unknown. Success generally high: at a site in Rwanda, young reared in 14 of 15 seasons; in Zimbabwe, 11 young fledged from 12 eggs; sometimes double-brooded if food abundant. First breeding possibly at 1 year old. Longevity of at least 10 years recorded.

Movements. Generally resident; local vertical movements recorded in Malawi, moving to higher elevations during hot summers.

Status and Conservation. Not globally threatened. CITES II. Widespread throughout S half of Africa, where often the commonest strigid in many habitats. Few data on densities; in Zimbabwe, c. 3 pairs found in 6 km². Fairly common in Tanzania, uncommon in Uganda and Kenya. Sometimes hit by road vehicles, or becomes trapped in barbed-wire fences or thorn bushes; other threats include local human persecution.

Bibliography. Baron (1984), Benson & Benson (1977), Benson *et al.* (1971), Cooper & Cooper (1992), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans (1994), Friedmann (1930), Fry *et al.* (1988), Frylink & Frylink (1996), Ginn *et al.* (1989), Grobler (1980), Harrison *et al.* (1997), Herholdt (1986b), Hockey *et al.* (1989), Jennings (1995), von Kaschke (1992), Kemp, A.C. & Calburn (1987), Kemp, A.C. & Kemp (1998), Kemp, A.C. *et al.* (1988), Kemp, M. *et al.* (1989), Lewis & Pomeroy (1989), Lloyd (1997), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Marshall (1996), Mendelsohn (1989), Muhweezi & Butynski (1990), Nel (1969), Penry (1994), Perrett (1980), von Petersdorff (1991, 1992), Pickford *et al.* (1989), Pinto (1983), Porter, Christensen & Schiermacker-Hansen (1996), Rutgers & Norris (1972), Short *et al.* (1990), Skinner *et al.* (1980), Snow (1978), Steyn (1982, 1984, 1992, 1994c), Tilson & LeRoux (1984), Vernon (1980), Voous (1988), Woodhouse (1991), Zimmerman, D.A. *et al.* (1996).

76. Greyish Eagle-owl

Bubo cinerascens

French: Grand-duc du Sahel **German:** Grauhuhu **Spanish:** Búho Ceniciento
Other common names: Vermiculated Eagle-owl

Taxonomy. *Bubo cinerascens* Guérin-Méneville, 1843, Adowa, Ethiopia. Usually treated as conspecific with *B. africanus*; differs, however, in plumage, bare-part colours, and not known to interbreed in overlap areas in Uganda and Kenya. Pale birds in Chad described as race *kollmannspergeri*, but probably only colour variant. Monotypic.

Distribution. Senegambia E to Ethiopia and Somalia, S to Cameroon, N Uganda and N Kenya.

Descriptive notes. c. 43 cm; c. 500 g. Relatively small eagle-owl, similar to *B. africanus*; compared with latter, has less spotting and more thin barring above, tail with narrower dark bars, browner below with very fine, dense dark vermiculations, and has greyish bill and dark brown rather than yellow eyes. Juvenile similar to *B. africanus*, but dark-eyed. **VOICE.** Male apparently gives loud 2-note hoot, second note deep and downslurred; differences from *B. africanus* unclear.

Habitat. Dry, rocky desert, semi-desert and hillsides with scattered trees and thorn scrub, and savanna with trees and bushes; in Somalia, also lowland woodland; avoids dense forest. In E of range, recorded visiting towns and suburbs.

Food and Feeding. Insects and other arthropods, small mammals and birds, reptiles and frogs. Nocturnal and crepuscular. Hunts from a perch, often beside road or track; probably also hawks aerial prey; recorded feeding on insects attracted to lights.

Breeding. Lays Nov–May in most of range; Aug in Nigeria, Mar–May in Somalia. Nest a scrape on ground on cliff ledge, sometimes in old tree nest of large bird. 1–3 eggs; incubation by female.

Movements. Resident; some local altitudinal movement to higher levels in hot summers.

Status and Conservation. Not globally threatened. CITES II. Generally rather uncommon throughout most of range. Uncommon in e.g. Senegambia, Uganda and Kenya; rare to uncommon in Liberia; fairly common in NW Somalia; thought to be common in Nigeria. In Sierra Leone, described as the commonest eagle-owl.

Bibliography. Ash & Miskell (1983b, 1998), Bannerman (1953), Barlow *et al.* (1997), Britton (1980), Cave & Macdonald (1955), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Demeter (1981, 1982), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Field (1998), Friedmann (1930), Fry *et al.* (1988), Gatter (1997), Giraudoux *et al.* (1988), Gore (1990), Green & Carroll (1991), Grimes (1987), Kemp & Kemp (1998), Lang (1969), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957, 1970), Short *et al.* (1990), Snow, D.W. (1978, 1979), Steyn (1984), Voous (1988), Zimmerman, D.A. *et al.* (1996).

77. Fraser's Eagle-owl

Bubo poensis

French: Grand-duc à aigrettes **German:** Guineahuhu **Spanish:** Búho de Guinea

Taxonomy. *Bubo Poensis* Fraser, 1853, Bioko (Fernando Póo).

May form superspecies with *B. vosseleri*. Sometimes treated as conspecific with latter, but geographical isolation and vocal differences, as well as differences in size and plumage, suggest distinct species. Monotypic.

Distribution. Liberia E to W Uganda, S through Congo basin to C Zaire and NW Angola; also Bioko (Fernando Póo).

Descriptive notes. 39–45 cm; male c. 575 g, female 685–815 g. Relatively small, with long ear-tufts; degree of rufous and extent of barring varies considerably among individuals. Facial disc pale rufous, edged in black; rufous with dark barring above, with pale scapular line; flight-feathers and tail narrowly barred with dusky and rufous; underparts pale rufous, fading to white on abdomen, all barred with black and rufous, chest with blotchy appearance; tarsus fully feathered; iris dark brown with pale blue eyelids; bill pale blue-grey. Juvenile pale whitish-rufous with thin dark bars, wings and tail as adult but much whiter.

scapulars; as adult by c. 1 year. **VOICE.** Loud purring trill, like sound of small engine; also drawn-out hooting "twowoooot", second part higher and more whistle-like, given every 3–4 seconds.

Habitat. Lowland evergreen and secondary forest, as well as forest edge and clearings; also plantations. Sea-level to 1600 m.

Food and Feeding. Insects, including beetles, grasshoppers, millipedes; also frogs and small birds, and small mammals such as mice, squirrels, fruit bats, tree hyraxes and small galagos; reports of occasional eating of fruit require corroboration. Nocturnal and crepuscular. Hunts mostly from perch.

Breeding. Poorly known; evidence suggests year-round laying, with no obvious seasonality; females with enlarged ovaries collected in Liberia in Jan, Sept, Nov, Dec; captive in Nigeria laid in Oct; nearly full-grown juveniles seen in Liberia in Jan and Aug. Nest possibly on ground or in tree hole; nestling found on ground, and another looking out of cavity. Details of clutch size, incubation and fledging period unknown; post-fledging dependence probably protracted, as juvenile does not moult mesopile plumage until 1 year old.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. CITES II. Common in Liberia and Cameroon; uncommon in Sierra Leone. In Liberia, total of at least 5 pairs in 4 areas each of 1 km², and 5 birds calling along 10 km of road. Status elsewhere difficult to assess; biology relatively unknown, and breeding undocumented. Although suffers from forest degradation in many areas, will tolerate some habitat disturbance and readily adapts to secondary habitats and logged forest, so effects may be less severe than suspected. Occurs in several protected areas throughout its range, such as Gola Forest Reserve (Sierra Leone), Dzanga-Ndoki National Park and Dzanga-Sangha Rainforest Reserve (Central African Republic) and Impenetrable (Bwindi) Forest National Park (Uganda); recorded also at Mt Cameroon and Mt Kupé (Cameroon).

Bibliography. Bannerman (1953), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dowsett (1989b, 1990), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Field (1998), Fry *et al.* (1988), Gatter (1988, 1997), Green & Carroll (1991), Grimes (1987), Hall & Moerau (1962), Helsen (1996), Kemp & Kemp (1998), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1970), Pérez del Val (1996), Pinto (1983), Snow (1978).

78. Usambara Eagle-owl

Bubo vosseleri

French: Grand-duc des Usambara **German:** Usambarahuhu **Spanish:** Búho de Usambara
Other common names: Nduk Eagle-owl

Taxonomy. *Bubo vosseleri* Reichenow, 1908, Amani, Tanzania.

May form superspecies with *B. poensis*. Sometimes treated as subspecies of latter; species status based on apparent differences in vocalizations (and apparent lack of response to taped *B. poensis* call), size and plumage, and isolated range. Monotypic.

Distribution. Usambara Mts of NE Tanzania; recently discovered in Uluguru Mts; also possible sighting in Nguru Mts.

Descriptive notes. 48 cm; 770–875 g. Closely resembles *B. poensis*; differs in larger size, browner upperparts, whiter underside less regularly barred and with faint streaking, and heavier blotching on breast, and dull yellow-orange or orange-brown eyes. Juvenile with white-spotted scapulars forming distinct line across wing. **VOICE.** Low-pitched, weak "po-a-po-a-po-a-po-a", 5–7 seconds in duration.

tion, accelerating and then decelerating, dropping in pitch; each phrase repeated at intervals of 30-60 seconds, up to 4 times; given only at night; captives sometimes gave double note similar to that of *B. poensis*.

Habitat. Evergreen montane forest at 900-1500 m; also recorded at forested edge of tea plantations in lowlands, down to 200 m, where possibly more frequent.

Food and Feeding. No information; probably similar to *B. poensis*.

Breeding. Estimated laying period Oct-Feb; no other information.

Movements. Presumably resident; possible vertical movements to lower levels in cold weather.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species; present in Tanzania-Malawi Mountains EBA. Following its discovery in 1908, not seen again until 1962. Scarcity may be attributable to its secretive and nocturnal habits. Population once thought to be no more than 200 birds, but increasing field work suggested more optimistic figure of 2 pairs/km², or nearly 500 pairs. Recent discovery of population in the Uluguru Mts indicates that, contrary to what was previously thought, it is unlikely that all breeding individuals are limited to a single subpopulation, and also that global

population size of species may be greater. Lowland areas with suitable habitat in Usambaras limited to c. 240 km². Forest clearance for subsistence farming, and cardamom and tea plantations, seen as a threat; cardamom, however, grown under intact canopy; several young birds found on ground in these cleared areas, so undisturbed forest perhaps not essential to species' survival. Nevertheless, conservation of forest, both montane and at lower levels, important; current projects designed to ensure survival, and even increase, of such habitat now under way.

Bibliography. Bennun & Njoroge (1996), Britton (1980), Britton *et al.* (1984), Brown (1977), Buckley & Matilya (1998), Clark & Mikkola (1989), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans, T.D. & Anderson (1992, 1993), Evans, T.D., Hague *et al.* (1994), Evans, T.D., Tye *et al.* (1997), Evans, T.D., Watson *et al.* (1994), Fry *et al.* (1988), Hipkiss *et al.* (1994), Hunter *et al.* (1996), Kemp & Kemp (1998), King (1978/79), Mackworth-Praed & Grant (1957), Moreau (1964), Olney (1984), Seddon *et al.* (1999), Short *et al.* (1990), Shuker (1993), Snow (1978), Stattersfield *et al.* (1998), Stuart & Hutton (1977), Stuart & Turner (1980), Stuart & van der Willigen (1978), Turner *et al.* (1991), Waiyaki (1996), White, G.B. (1974), Zimmerman, D.A. *et al.* (1996).

79. Forest Eagle-owl

Bubo nipalensis

French: Grand-duc du Népal

German: Nepaluhu

Spanish: Búho Nepali

Other common names: Spot-bellied Eagle-owl

Taxonomy. *Bubo nipalensis* Hodgson, 1836, Nepal.

Possibly forms superspecies with *B. sumatranus*. Two subspecies recognized.

Subspecies and Distribution.

B. n. nipalensis Hodgson, 1836 - Himalayas from N Uttar Pradesh E to SW China (Yunnan), S to Cambodia and Vietnam; also S India in Western Ghats and Tamil Nadu.

B. n. blighi Legge, 1878 - Sri Lanka.

Descriptive notes. 51-64 cm. Large, powerful, dark brown owl, with well-developed, outward-slanting ear-tufts composed of feathers of different sizes. Facial disc whitish; dark brown above, mottled and barred with buffy-white; below, buffy-white, barred with blackish on throat and breast, with dark brown v-shaped spots on lower breast and abdomen; tarsus fully feathered; iris brown to hazel-brown; bill dull wax-yellow to yellow; feet dusky yellow. Juvenile conspicuously pale, buff to whitish, narrowly barred above and below; moults into adult plumage at 1 year. Race *blighi* smaller, darker above, less barred below. **Voice.** Deep, low, resounding "hoo hoo", 2 seconds between notes; also loud, mournful scream with rising and falling rhythm.

Habitat. Dense evergreen and moist deciduous forest, usually near water, montane wet temperate forest, and dense riparian gallery forest; hunts also in scrub, bamboo jungle, thin deciduous forest, sometimes edges of clearings. From 300 m to 2130 m, locally to 3000 m in Himalayas.

Food and Feeding. Mainly large birds; also mammals, and reptiles and fish; occasionally carrion. Bird prey include large phasianids, especially junglefowl, peafowl and pheasants, e.g. Kalij Pheasant (*Lophura leucomelanos*); mammals include hares, jackals, barking-deer fawns; monitor lizards sometimes taken. Mostly nocturnal; occasionally hunts during day. Bold and powerful hunter; hunts from perch, or pounces on roosting birds or other prey.

Breeding. Lays Feb-Mar in Himalayas and Nepal; Dec-Jan in S India; Apr-May in Sri Lanka. Nest in large tree cavity or abandoned nest of raptor; also lays on bare soil in cave or sheltered fissure in rock wall. Usually 1 egg; reported to be fierce in defence of eggs or nestlings.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Rare and local in Indian Subcontinent, including Sri Lanka; at best uncommon in Thailand; rare to very rare in other parts of range; in Myanmar, reported to be well distributed but much overlooked. Appears to be dependent on continued existence of tropical lowland and hill forest, habitat under severe pressure throughout S Asia; no indication of ability to colonize degraded areas.

Bibliography. Ali (1996), Ali & Ripley (1981), Ali *et al.* (1996), Brack (1996), Daniels (1997), Deignan (1945), Delacour & Jabouille (1940), Duckworth *et al.* (1998), Gokula & Vijayan (1997), Grimmett *et al.* (1998), Henry (1998), Inskipp & Inskipp (1991), Lamsfuss (1998), Lekagul & Round (1991), Majumdar *et al.* (1992), Neelakantan (1965), Riley (1938), Ripley (1982), Smythies (1986), Thewlis *et al.* (1998), Voous (1988), Wang Sung (1998), Zhao Zhengjie (1995).

80. Barred Eagle-owl

Bubo sumatranus

French: Grand-duc bruyant

German: Malaieuhu

Spanish: Búho Malayo

Other common names: Malay/Malaysian Eagle-owl

Taxonomy. *Strix Sumatrana* Raffles, 1822, Sumatra.

Possibly forms superspecies with *B. nipalensis*. Suggested that it may have some morphological and vocal affinities with African *B. shelleyi*. Bornean population sometimes separated racially (as *tenuifasciatus*). Two subspecies recognized.

Subspecies and Distribution.

B. s. sumatranus (Raffles, 1822) - extreme S Myanmar and peninsular Thailand S to Sumatra, including Bangka I.

B. s. strepitans (Temminck, 1823) - Borneo, Java and Bali.

Descriptive notes. 40-46 cm. Relatively small eagle-owl with long, outward-directed ear-tufts. Facial area dirty whitish, ear-tufts dark brown, finely marked with white; blackish-brown above, barred with rufous-buff, some buff-white on scapulars; flight-feathers and tail widely barred; greyish-white below, tinged rufous-brown on chest, and barred with brown; tarsus fully feathered; iris dark brown; bill and feet yellow. Juvenile buffy-white, barred with dark brown. Race *strepitans* larger, barring below stronger and denser; Bornean birds somewhat intermediate. **Voice.** Loud "whoa-who, whoa-who", ending with deep groan,

each hoot with downward inflection; also various shrieks and cackles.

Habitat. Lowland evergreen forest and semi-evergreen forest, and forest edge and clearings; also secondary growth and old plantations, and well-wooded gardens. Mostly from lowlands to 600 m, locally to 1000 m; in Malay Peninsula recorded exceptionally to 1400 m, and in Java to 1600 m.

Food and Feeding. Diet includes large insects, as well as small mammals, especially rodents, and snakes and small birds; probably takes some larger prey, too. Nocturnal and crepuscular. Hunts from perch, and hops well on ground; flies fast and low from diurnal roost at dusk.

Breeding. In Peninsular Malaysia, fledglings found in Jan, late Feb and Apr-Jun; in Sumatra, nestlings and young fledglings in Mar-May; in Borneo, young in Feb-Mar, reported to breed before rice

harvest; in Java, eggs in Feb-Apr, chicks in May-Jun. Nest in tree cavity; in Sumatra and Java, often on bird's-nest fern (*Asplenium nidus*). Usually 1 egg; incubation and fledging periods unknown.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Little information available. Uncommon in Thailand; uncommon to fairly common in Peninsular Malaysia; sparingly distributed throughout Borneo; locally fairly common in other parts of range. Ability to adapt to disturbed forest and to accept second-growth habitats suggests that species is not in any immediate danger.

Bibliography. Andrew (1992), Delacour (1947), Glenister (1951), Hellebrekers & Hoogerwerf (1967), Hoogerwerf (1949a), Holmes (1996), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Meyer de Schauensee & Ripley (1940), Nash, S.V. & Nash (1985, 1988), Smythies (1981, 1986), Tobias (1995), Vowles & Vowles (1984), Wells (1999).

81. Shelley's Eagle-owl

Bubo shelleyi

French: Grand-duc de Shelley

German: Bindenuhu

Spanish: Búho Barrado

Other common names: Banded Eagle-owl

Taxonomy. *Huhua shelleyi* Sharpe and Ussher, 1872, Fantee, Ghana.

No obvious close relatives; may possibly have some vocal and morphological affinities with *B. sumatranus* of SE Asia. Monotypic.

Distribution. Sierra Leone and Liberia E to Ghana, and S Cameroon and N Gabon E to N Zaire.

Descriptive notes. c. 61 cm; 1 male 1257 g. Big, dark, heavily barred eagle-owl with "tousled" brown ear-tufts. Facial disc creamy to tawny with dusky bars, edged in black; head dusky brown with few white feathers on nape; upperparts dark brown with dark buff bars; flight-feathers and tail barred dusky and dark buff; breast and belly cream to white with bold, broad dusky bars; tarsus fully feathered, toes pale cream; iris dark brown; bill dull yellow. Juvenile has large areas of white on head, with sooty barring. **Voice.** Loud, wailing "kooouu", given irregularly at intervals of some seconds; continuous soft peeping when stressed.

Habitat. Lowland primary rainforest and forest edge.

Food and Feeding. Virtually nothing known; observed eating large flying squirrel. Large size and powerful feet suggest that variety of mid-sized to large prey taken. Captive bird required c. 110 g of flesh per day.

Breeding. In Liberia, intense calling in Mar; in Cameroon, adult roosting with possible juvenile in Dec; in Zaire, large nestling found in Sept, nestling in mesoptile plumage early Nov, and fledged young in Dec. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Rare and very local throughout its range. Reported as rare to uncommon in Liberia. Known from only 1 record in Sierra Leone. One of the least-known of African owls; breeding and general ecology almost undocumented. Owing to its rarity and fragmented distribution, and poorly documented biology, conclusive comments on its status difficult. Conservation status probably merits reappraisal.

Bibliography. Bannerman (1953), Chapin (1960), Colston & Curry-Lindahl (1986), Dowsett (1989b), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Field (1998), Fry *et al.* (1988), Gartshore (1989), Gatter (1988, 1997), Grimes (1987), Kemp & Kemp (1998), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1970), de Roo (1966a), Schouteden (1966), Snow (1978), Thiollay (1985).

82. Verreaux's Eagle-owl

Bubo lacteus

French: Grand-duc de Verreaux

German: Blaßuhu

Spanish: Búho Lechoso

Other common names: Giant/Milky Eagle-owl

Taxonomy. *Strix lactea* Temminck, 1820, Senegal.

No close relatives. Monotypic.

Distribution. Tropical W Africa patchily from Senegal and C Mali E to Cameroon, and from C Sudan, N Ethiopia and Somalia S to South Africa.

Descriptive notes. 60-65 cm; wingspan 140 cm; male 1615-1660 g, female 2475-3115 g. Largest African owl; distinct dusky ear-tufts. Off-white facial disc rimmed in black; upperparts grey-brown, scapulars and wing-coverts with some white; flight-feathers and tail barred dusky and light brown; underparts whitish with fine dark grey-brown vermiculations, darkest on upper breast; tarsus and toes fully feathered; iris brown, with conspicuous pink eyelids; bill pale horn, with black bristles at base. Juvenile has body and head grey-brown with broad bars, facial disc less pronounced, smaller ear-tufts. **Voice.** Deep, grunting "gwok gwok" notes,

uttered in uneven series of 1-5 hoots, may carry up to 5 km; also whining calls.

Habitat. Open thorny savanna and semi-desert with scattered trees; riparian areas with stands of large trees, often adjoining savanna; also small forest patches, open woodland, tall moist woodland and stands of exotic trees; absent only from dense forest and bare desert. In W Africa, appears to prefer riparian habitat. From sea-level to 3000 m.

Food and Feeding. Opportunistic, diet based on prey availability. Mostly medium-sized mammals and larger birds; also reptiles, amphibians, fish, insects, spiders and scorpions, and carrion. Diversity of mammal prey, from young monkeys, warthog piglets, mongooses and hyraxes to fruit bats,

cane rats and gerbils; birds from estrildids and other passerines up to ducks, Black-headed Heron (*Ardea melanocephala*), Secretarybird (*Sagittarius serpentarius*) and other raptors; excessively mobbed by birds if disturbed from daytime roost. Only major predator of South African hedgehogs (*Aterix*), leaving characteristically peeled pelts uneaten. At SW limit of range, birds, especially herons, most important. Requires c. 5% of body weight in food per day. Sometimes caches excess food. Rarely drinks. Crepuscular and nocturnal, but records of killing animals that pass beneath its roost during day; inquisitive, attracted to any commotion. Hunts from perch, gliding down to capture prey, killing it with its heavy feet and long talons along with impact of the blow; occasionally flushes prey in low searching flight. Also crashes into foliage after roosting birds or arboreal mammals; runs on ground, wades into water after fish; hawks flying insects, seizing these with its feet.

Breeding. Lays Mar-Sept, peak in Jun-Aug; Jan-Mar in W, Oct-Jan in NE. Monogamous. Uses old stick nest of other bird such as eagle, vulture, Secretarybird, Hamerkop (*Scopus umbretta*) or corvid, or uses nest colony of weavers (*Bubalornis*, *Philetaurus*) as platform; sometimes on ground, e.g. beneath hollowed-out roots of tree; occasionally lays in cavity or tree hollow; may usurp nests of smaller species; often same site used yearly; average territory size c. 7000 ha. 1-2 eggs; incubation 32-39 days, by female, fed by male; chicks hatch asynchronously with up to 7-day interval, younger either starves or is killed by sibling, occasionally both raised; chick with creamy-white down, brooded up to c. 20 days by female, male provides food and transfers it to female, who feeds chick; young leaves nest before able to fly, fledges within following 2 weeks at 62-63 days, hides and remains inactive until c. 3 months old, depending on parents for food; juvenile sometimes stays with parents for 2 years and helps raise next brood. Pair at E Cape raised a chick in 4 successive years. First breeding at 3-4 years old; annually thereafter, or irregularly at intervals of 2-4 years, probably related to prey abundance but exact factors unknown. Captive individual survived 15 years.

Movements. Resident, even in arid areas; only local dispersal of young.

Status and Conservation. Not globally threatened. CITES II. Common and widespread throughout most of its range; generally less common in W, where also more local. Common in Senegambia, but considered uncommon in Sierra Leone, and rare in Liberia, Ghana and Cameroon; recent observations suggest possibly quite common in Benin; species may be overlooked in areas where it prefers riparian habitat, as in W Africa. Few records from W & SE Tanzania, N Kenya or coastal regions of E. Able to survive in wide range of habitats, and adaptable, so not vulnerable to forest clearance. Main threat probably human persecution.

Bibliography. Agutu (1994), Ash & Miskell (1998), Avery *et al.* (1985), Bannerman (1953), Barlow *et al.* (1997), Benson & Benson (1977), Benson *et al.* (1971), Boshoff (1987, 1996), Brown (1965), Bursell (1992), Cave & Macdonald (1955), Cheke & Walsh (1996), Claffey (1998), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dugmore (1997), Elgood *et al.* (1994), Field (1998), Friedmann (1930), Fry *et al.* (1988), Gatter (1997), Ginn *et al.* (1989), Giraudoux *et al.* (1988), Gore (1990), Grimes (1987), Hammer (1981), Harrison *et al.* (1997), Herholdt (1993a), Ives (1991), Kemp & Calburn (1987), Kemp & Kemp (1998), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Penny (1994), Pickford *et al.* (1989), Pinto (1983), Pitman & Adamson (1978), Schwab & Wright (1990), Short *et al.* (1990), Smart & Taylor (1990), Snow, D.W. (1978, 1979), Steyn (1982, 1984, 1994c), Vernon (1980), Wilson & Wilson (1981), Zimmerman, D.A. *et al.* (1996).

83. Dusky Eagle-owl

Bubo coromandus

French: Grand-duc de Coromandel **German:** Koromandeluhu **Spanish:** Búho de Coromandel
Other common names: Dusky Horned Owl

Taxonomy. *Strix coromanda* Latham, 1790, Coromandel Coast.
No obvious close relatives. Two subspecies recognized.

Subspecies and Distribution.

B. c. coromandus (Latham, 1790) - Pakistan, N & C India and S Nepal E to Assam and Bangladesh; apparently this race also in E China.

B. c. klossi Robinson, 1911 - W & S Myanmar, W Thailand.

Descriptive notes. 48-53 cm. Large, greyish owl with prominent ear-tufts rounded at tips. Pale facial disc framed by narrow black lines; above, dark brown with greyish tinge, obscurely marked with long, narrow, widely spaced streaks of dark brown, and buffy-white spots on wing-coverts; tail dark brown, barred, paler at tip; below, very pale buffish-grey with narrow black streaks; tarsus fully feathered; iris yellow; bill greyish-white, tip pale yellowish-horn; feet pale grey-brown. Juvenile mostly rufous, with greyer head. Race *klossi* darker, more brown. **VOICE.** Accelerating "wo wo wo wo-wo-wowowo", becoming softer with each note; low, deep rumbling "woo-woo-woo"; loud, piercing call; calls during day or night.

Habitat. Open, level areas with plenty of woodland, generally near water; riparian forest, old plantations, e.g. of mango, thickly foliated groves and roadside trees; has adapted to irrigated forest plantations. Lowlands, to c. 250 m.

Food and Feeding. Birds, especially crows (*Corvus*), but ranging from pigeons and doves, parakeets, coucals (*Centropus*) and coraciiforms to hawks, and waterbirds such as waders, coots (*Fulica*) and pond-herons (*Ardeola*); also small to medium-sized mammals, such as rats, hares and squirrels, and porcupine recorded as prey; also takes reptiles and amphibians, and fish; insects also recorded, mainly water beetles (*Dytiscus*), and birds' eggs. Semi-diurnal; quite often active during daylight, especially in dull weather. Hunting methods poorly documented; hunts from perch, probably also in searching flight, and on ground, and wades in shallow water, catches birds as they fly in to roosts. Decapitates large prey before taking to feeding perch or nest.

Breeding. Lays late Nov-Apr, mainly Dec-Jan, later in S; fledglings found from early Feb. Lays in old stick nest of raptor, commonly kite, vulture or eagle, high up in tree fork; record of ground nesting in Bombay; reports of occasionally building own nest, or lining old one with greenery, unconfirmed, highly doubtful. Usually 2 eggs, sometimes 1 or 3; incubation by both sexes reported, period unknown; eggs hatch asynchronously, usually only older, stronger nestling reaches maturity; chick with white down; fledging period and dependence unrecorded.

Movements. Resident; old records from Peninsular Malaysia presumed to have involved vagrants, but no evidence of any regular movements.

Status and Conservation. Not globally threatened. CITES II. Little information. Widespread but uncommon in India, more frequent in Pakistan, local and rare in Nepal and Bangladesh. Said to be fairly common in Myanmar, at least formerly, but current status there not known; status in Thailand unclear, apparently extremely rare, only handful of records ever, none of breeding, and possibly only winter visitor or vagrant; only 4 records from Peninsular Malaysia, last in 1915, considered to

have involved vagrants from farther N. Possible that range of race *klossi* has contracted, thus explaining paucity of modern records in well-watched regions; indeed, current evidence indicates that population at very low level, perhaps threatened. Chinese population of nominate race virtually unknown; requires further investigation.

Bibliography. Ali (1996), Ali & Ripley (1981), Daniels (1997), Eates (1939), Grimmett *et al.* (1998), Inskipp & Inskipp (1991), Lekagul & Round (1991), Mahabal & Lamba (1987), Medway & Wells (1976), Mirza (1985), Mukherjee (1995), Ripley (1982), Roberts (1991), Round (1988), Smythies (1986), Thompson *et al.* (1993), Wang Sung (1998), Wells (1999), Zhao Zhengjie (1995).

84. Akun Eagle-owl

Bubo leucostictus

French: Grand-duc tacheté **German:** Schwachschnabeluhu **Spanish:** Búho de Akún
Other common names: Sooty Eagle-owl

Taxonomy. *Bubo leucostictus* Hartlaub, 1855, Dabocrom, Ghana.

No obvious close relatives. Monotypic.

Distribution. Patchily from Sierra Leone and Liberia E to Nigeria and Cameroon, S to mouth of R Congo, Cabinda and probably NW Angola, and across N Zaire.

Descriptive notes. 40-46 cm; male 485-535 g, female 525-610 g. Relatively small eagle-owl, with comparatively small feet and weak bill. Facial disc light rufous with pale rings, dark rim; head and ear-tufts dark brown with white spots; upperparts, including flight-feathers, brown to rufous-brown with pale dusky brown bars, scapulars with white outer webs; tail banded, with conspicuous white tip; throat white; breast light rufous-brown, spotted and barred dark, rest of underparts white with thin rufous vermiculations and large blackish spots; tarsus feathered; iris pale yellow; bill greenish-yellow. Juvenile has head and body whitish with rufous barring, contrasting brown wings and tail; as adult at 1 year. **VOICE.** Low, accelerating clucking rattle, "tok tok tok-ok-ok-ok", given infrequently; quacks in alarm.

Habitat. Primary and secondary lowland rainforest, mainly at edges and clearings; also forest along rivers and forested river islands; in Liberia, recorded also in swampy areas of virgin forest and in farmland areas with tall trees.

Food and Feeding. Mainly insects, such as beetles, cicadas and locusts; vertebrates not recorded in diet; captive birds refused larger rodents, but ate oil-palm fruit; small feet and weak bill suggest incapable of overpowering large birds or mammals. Nocturnal, emerging at dusk. Hunts from perch in middle storey, often near clearing or track; flies low down along roads and open trails. Seizes prey from foliage or the ground; also catches insects on wing, observed hawking cockroaches at dusk. Food held in foot, and broken into pieces by nipping with bill.

Breeding. Gonadal condition of specimens indicates laying in Nov-Dec in Sierra Leone, Nov-Jan in Gabon, and Mar and Aug-Sept in Zaire; in Liberia, nestlings in Feb-Apr and juvenile in Jul. Nest apparently on ground. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Patchy distribution with restricted pattern of occurrence; usually considered uncommon. Uncommon in Sierra Leone, and thought rare in Nigeria; found to be common in Liberia, with up to 1 pair/km² in NW. Although poorly known, and breeding more or less undocumented, species is easily overlooked; possibly more common than records suggest. More study needed to assess its status, and any possible impacts of logging.

Bibliography. Bannerman (1953), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (1999), Elgood *et al.* (1994), Field (1998), Fry *et al.* (1988), Gatter (1988), Green & Rodewald (1996), Grimes (1987), Jellicoe (1954), Kemp & Kemp (1998), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1970), Pinto (1983), Snow (1978), Stephenson & Newby (1997), Thiollay (1985).

85. Philippine Eagle-owl

Bubo philippensis

French: Grand-duc des Philippines **German:** Streifenuhu **Spanish:** Búho Filipino
Other common names: Philippine Horned Owl

Taxonomy. *Pseudopteryx philippensis* Kaup, 1851, Philippines.

No obvious close relatives. Two subspecies recognized.

Subspecies and Distribution.

B. p. philippensis (Kaup, 1851) - Luzon and Catanduanes.

B. p. mindanensis (Ogilvie-Grant, 1906) - Samar, Leyte and Mindanao; recently recorded on Bohol.

Descriptive notes. 40 cm. Smallish, rufous eagle-owl with small, outward-slanting ear-tufts. Facial disc rufous-buff; head, breast and upperparts tawny-rufous with broad dark brown stripes; wings and tail barred dark brown and rufous-buff; upper throat unstreaked buff; lower breast to belly buffy-white, streaked dark brown; tarsi feathered to base of toes; iris yellow; bill bluish-horn; toes bluish to flesh-coloured. Juvenile undescribed. Race *mindanensis* darker, more heavily streaked. **VOICE.** Uncertain, confused with other Asian forest owls.

Habitat. Forest, often near rivers or lakes;

occurs at lower elevations.

Food and Feeding. No information; large and powerful feet suggest that diet composed of small mammals or birds.

Breeding. No information.

Movements. Resident.

Status and Conservation. ENDANGERED. CITES II. Rare; very few recent records, all from Luzon, except for unexpected sighting in 1994 on Bohol, where previously unrecorded. Rapid population decline due to extensive lowland habitat destruction, and possibly hunting. The pres-

ence of more than 10 individuals kept in Manila Zoo in 1994 would seem to indicate that species may be locally less rare than scarcity of records suggests.

Bibliography. Anon. (1997b), Brooks & Dutton (1997), Brooks *et al.* (1996), Collar *et al.* (1994), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), Heaney & Regalado (1998), Oliver & Wirth (1996), Gogorza y González (1987), Gonzales (1983), McGregor (1909-1910, 1921), Ogilvie-Grant (1894), Parkes (1973), duPont (1971), Poulsen (1995), Rabor (1938a), Rand & Rabor (1960), Whitehead (1899).

86. Blakiston's Eagle-owl

Bubo blakistoni

French: Grand-duc de Blakiston **German:** Riesenfischuhu **Spanish:** Búho Manchú
Other common names: Blakiston's Fish-owl

Taxonomy. *Bubo blakistoni* Seebohm, 1884, Hokkaido, Japan.

Sometimes placed in genus *Ketupa*, and has been treated as forming superspecies with, or even conspecific with, *K. zeylonensis*. Skeletal details, however, especially skull morphology, appear identical to those of *Bubo* (e.g. *B. bubo*) and different from osteology of *Ketupa*. Four subspecies recognized.

Subspecies and Distribution.

B. b. piscivorus Meise, 1933 - W Manchuria (W of Great Khingan Mts).

B. b. doerriesi Seebohm, 1895 - SE Siberia and extreme NE China, to Korean border.

B. b. karafutonis Kuroda, 1931 - Sakhalin I.

B. b. blakistoni Seebohm, 1884 - Hokkaido and S Kuril Is.

Descriptive notes. 60-72 cm; wingspan 180-190 cm. One of largest of all owls; ear-tufts broad, long, horizontal. Facial disc pale grey-brown; upperparts buff-brown, broadly streaked, wings barred buff and dark brown; tail almost white, barred dark; white throat; below, pale buffish-brown with long, thin streaks; tarsi feathered almost to base of toes; iris orange-yellow; bill pale grey-horn, yellowish at tip; toes dark brown-grey. Juvenile with spots and whitish feather edgings above. *Race doerriesi* larger, with white crown patch; *piscivorus* paler; *karafutonis* smaller and darker than nominate, tail more narrowly barred. **VOICE.** Territorial call short, deep

"boo-bo-boo" or "shoo-hoo"; elaborate duets; begging call long, slurred "peer-peer-peer".

Habitat. Dense broadleaf or mixed broadleaf/coniferous forest along clear rivers, favouring tributary confluences where some slow-flowing channels; steep-sided wooded valleys near fast-flowing rivers; also taiga rivers which do not freeze in winter; in Kurils, dense conifer forest adjacent to water, including sea coast. Also forages on rocky coasts. Lowlands.

Food and Feeding. Primarily fish, including large ones; also crabs, crayfish, frogs, and birds up to size of grouse (Tetraonidae); occasionally bats in flight. In autumn and winter, diet includes many crayfish, other crustaceans, as well as small mammals; sometimes cats and small dogs. Forages mainly at night (fish) or dusk (frogs); also by day. Hunts from low branch, log or bank overlooking river shallows; often walks about on ground, occasionally stands in water; jumps on prey and kills with talons; sometimes swoops to catch fish near surface, or dives feet first into deep water. In winter, will wait by air holes in ice; sometimes up to 5-6 individuals together.

Breeding. Lays late Feb-mid Mar, when snow cover still deep. Probably pairs for life. Nest a spacious hole up to 18 m above ground in large hollow tree, or in nestbox, or in fallen tree, sometimes on ground in forest; highly territorial, in Siberia territory covering 6-12 km of river valley. Courtship feeding begins 4 days before first copulation; most copulations around sunset. Usually 2 eggs (1-3); incubation 35-37 days, by female, fed on nest 3-5 times nightly by male; female leaves only to defecate and preen, travelling no more than 100 m from nest; chick with white down; young leave nest at 35-40 days, remain with parents for several months; juveniles sometimes dependent on adults for up to 1 year, especially during harsh winters. Apparently breeds only in alternate years. Lifespan probably 20 years or more.

Movements. Resident.

Status and Conservation. **ENDANGERED.** CITES II. One of world's rarest owls. Numbers in Russia, including Sakhalin and S Kuril Is. estimated at 300-400 pairs in 1984; formerly present throughout Hokkaido (Japan), but now confined to E & C parts, where 80-100 birds estimated in late 1980's, with only c. 20 pairs breeding in any year; in NE China extremely rare and local, possibly now extinct. Has declined massively over entire range, especially since 1950's; on R Bikin, in Ussuriland, decrease from estimated 70 birds (26 pairs) in mid 1970's to current total of 15 pairs or fewer. Main threats are development of riverside habitats and deforestation, especially destruction of taiga forest in Far East and Japan; on lower R Bikin, human population pressure forcing it to move to less productive rivers. Depletion of fish stocks through overfishing also an adverse factor. Furthermore, this species' habit of concentrating around fishing holes in Siberia renders it vulnerable to hunters and fishermen; also persecuted by fur-trappers, and sometimes dies in traps set for mink; hunted for food locally in Siberia. Provision of nestboxes has achieved some success on Kunashiri I and Hokkaido, where pairs have bred in these artificial nests annually since 1983. Attempts at captive-breeding unsuccessful.

Bibliography. Berezan (1993), Borodin (1984), Brazil (1985, 1989, 1991), Brazil & Yamamoto (1989a, 1989b), Cheng Tsohsin (1987), Clark & Mikkola (1989), Collar & Andrew (1988), Collar *et al.* (1994), Dykhan & Kiseleiko (1988), Échécoar & Hùe (1978), Flint *et al.* (1984), Hayashi (1997), Knystautas (1993), Mikhailov & Shibeve (1998), Nechaev (1991), Pukinsky (1973, 1974), Sasaki & Fujimaki (1995), Spangenberg (1965), Stepanyan (1990), Voous (1988), Yamamoto (1994), Yanagawa (1993), Zhao Zhengjie (1995).

Genus KETUPA Lesson, 1830

87. Brown Fish-owl

Ketupa zeylonensis

French: Kétoupa brun **German:** Fischuhu **Spanish:** Búho Pescador de Ceilán
Other common names: Ceylon Fish-owl, Brown Fishing-owl

Taxonomy. *Strix zeylonensis* J. F. Gmelin, 1788, Sri Lanka.

Genus *Ketupa* sometimes merged with *Bubo*, or treated as a subgenus. Present species then considered by some authors as forming superspecies with, or even conspecific with, *B. blakistoni*, but skeletal details, especially skull osteology, of latter appear identical to those of *Bubo* (e.g. *B. bubo*) and unlike *Ketupa*. Four subspecies recognized.

Subspecies and Distribution.

K. z. semenowi Zarudny, 1905 - S Turkey, Israel (probably extinct) and N Syria to NW India.

K. z. leschenaulti (Temminck, 1820) - India (S of Himalayas) E to Myanmar (except NE) and Thailand.

K. z. zeylonensis (J. F. Gmelin, 1788) - Sri Lanka.

K. z. orientalis Delacour, 1926 - NE Myanmar to SE China (Guangxi, Guangdong), S to Malay Peninsula, Indochina and Hainan I.

Descriptive notes. 50-57 cm; c. 1105 g. Large, flat-headed owl, with noticeable ear-tufts usually held horizontally. Facial disc buff, with dark brown upper cheeks; crown and upperparts pale chestnut with dark brown mottling and streaking; wing-coverts and flight-feathers dark brown, mottled with whitish-buff; tail barred brown and buff; throat white; underparts buffish-white with dark shaft streaks and thin rufous cross-lines; tarsus unfeathered; iris bright yellow; bill green-grey, tip darker; legs and feet yellowish. Juvenile less mottled, more narrowly streaked. *Race leschenaulti* larger and paler than nominate; *orientalis* darker, with

more black above, stronger buff below; *semenowi* very pale, brighter-coloured. **VOICE.** Deep, hollow, humming "boom boom" or "boo o-boom", repeated at intervals; also more muted "hu-who-hu".

Habitat. Deciduous, semi-deciduous and open evergreen woodland, well-vegetated ravines, steep banks and canalsides, old plantations and groves with mature trees, almost always near water; in Middle East, occupies undisturbed wadis and valleys with trees and bushes in hilly areas; streamside forest in China. Lowlands and foothills, to c. 1500 m; in Thailand, from plains up to 800 m; in China, at 600-1900 m.

Food and Feeding. Mainly fish, frogs and freshwater crabs; also crayfish, snakes and lizards, occasionally rodents and birds; also insects, e.g. large beetles. Occasional records of feeding on carrion; observed feeding on crocodile carcass. Nocturnal and crepuscular, often diurnal. Hunts from perch overlooking water; swoops down and dangles legs in water, seizing prey in talons; also wades after food.

Breeding. Lays Nov-May in Indian Subcontinent, mostly Jan-Feb in N. Apr in Sri Lanka; eggs in Dec in Malay Peninsula; breeds in dry monsoon season when water levels low and fish easily located. Presumed to pair for life. Nest in hollow or suitable depression in tree, or in old raptor nest, or on rock ledge or steep stream bank, usually near water, recorded at 4-21 m above ground; in India, sometimes on ruined building. Usually 2 eggs (1-3); incubation 34-38 days, by female; reports of male assisting incubation unconfirmed, highly improbable; fledging c. 51 days.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Generally uncommon. Apparently more numerous in Sri Lanka, where said to be possibly one of commonest strigids; local in Bangladesh, and local and uncommon in E of range. Rare in W of range; in Middle East, either extinct or on the verge, with last confirmed sighting in mid 1970's, and none located in surveys in mid 1980's; 1 substantiated record in S Turkey in 1990; extirpation in Israel thought to be result of mass poisoning of rodents in 1950's by agricultural chemicals, as well as draining of L Hula and adjacent swamp, and pollution of rivers; possibly survives in N Syria, perhaps also SE Iraq; almost certainly extinct in N Israel and S Syria. Doubtful if any remain in Iran, and very rare in Pakistan.

Bibliography. Ali (1996), Ali & Ripley (1981), Beaman & Madge (1998), Busch (1986), Cramp (1985), Deignan (1945), Échécoar & Hùe (1978), Evans (1994), Gregson (1986), Grimmett *et al.* (1998), Hùe & Échécoar (1970), Inskipp & Inskipp (1991), Lekagul & Round (1991), Magnin (1991), Medway & Wells (1976), Mendelsohn (1996), Mikkola (1983), Mukherjee (1995), Paz (1987), Phillips (1978), Porter, Christensen & Schiormacker-Hansen (1996), Ripley (1982), Roberts (1991), Rooke (1998), Schluter (1987, 1988), Shirihai (1996), Smythies (1986), Snow & Perrins (1998), Turnbull (1988), Voous (1988), Wells (1999), Zhao Zhengjie (1995).

88. Tawny Fish-owl

Ketupa flavipes

French: Kétoupa roux **German:** Himalayafischuhu **Spanish:** Búho Pescador Leonado

Taxonomy. *Cultrungius Flavipes* Hodgson, 1836, Nepal.

Genus *Ketupa* sometimes merged with *Bubo*, or treated as a subgenus; separated on basis of slight differences in skull morphology. Probably forms superspecies with *K. ketupa*, the two replacing each other geographically. Monotypic.

Distribution. Himalayas from NW India, Nepal and Bhutan to NE India, E to C China and Taiwan, and S to N Bangladesh, NE Myanmar and S Indochina.

Descriptive notes. 48-55 cm. Large fish-owl with prominent horizontal ear-tufts. Facial disc orange-rufous with indistinct dark border; above, rich orange-rufous or tawny with broad blackish shaft streaks, scapulars and wing-coverts with much buffy colour; flight-feathers barred dark brown; tail dark brown, barred buffy; usually well-defined white throat patch; below, orange-rufous with dark brown shaft streaks, broadest on breast; tarsi feathered for half way or more at front; iris yellow; bill horn-black, sometimes yellowish at tip; feet yellowish-grey or slaty-green. Distinguished from *K. ketupa* by larger size, feathered tarsi, also tawny

above instead of dark brown, and brighter orange-rufous below. Juvenile spotted above, streaks below more obscure. **VOICE.** Territorial call deep "who-who"; also cat-like mewling.

Habitat. Deep, wooded ravines, stream banks and pools in heavy broadleaf forest near water; prefers running water. From plains to c. 1500 m; usually at 250-365 m in Nepal, locally to 1525 m; occasionally to 2450 m in India.

Food and Feeding. Diet mostly fish; also crayfish, crabs, rodents, lizards, large beetles; often kills large birds, including partridges, pheasants and junglefowl; remains of a porcupine (*Hystrix brachyura*) found at nest. Crepuscular and nocturnal; frequently diurnal, active even in bright daylight. Hunts from perch, swooping down to capture fish near surface of water.

Breeding. Lays Nov-Feb in W of range. Nest in old nest of raptor high in tree, or in hollow in ravine or river bank. 2 eggs, sometimes 1. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. In W, very rare and local to uncommon; status elsewhere very poorly known, possibly not uncommon locally. Very few observations, however, and probably rare over most of its range. Forest destruction a likely threat.

Bibliography. 89. Buffy Fish-owl

Ketupa ketupu

French: Kétoupa malais **German:** Sundafischuhu **Spanish:** Búho Pescador Malayo
Other common names: Javan/Malay/Malaysian Fish-owl

Taxonomy. *Strix Ketupa* Horsfield, 1821, Java.

Genus *Ketupa* sometimes merged with *Bubo*, or treated as a subgenus; separated on basis of slight differences in skull morphology. Probably forms superspecies with *K. flavipes*, the two replacing each other geographically. Race *minor* sometimes incorrectly referred to as "*buetikoferi*". Race *aagaardi* intergrades with nominate *ketupu*. Four subspecies recognized.

Subspecies and Distribution.

K. k. aagaardi (Neumann, 1935) - S Assam to S Thailand and Vietnam.

K. k. ketupu (Horsfield, 1821) - Malay Peninsula, Riau Archipelago, Sumatra, Bangka, Belitung, Java, Bali, and Borneo (except NW).

K. k. minor Büttikofer, 1896 - Nias I, off W Sumatra.

K. k. pageli (Neumann, 1935) - NW Borneo.

Descriptive notes. 38-44 cm. Smallest fish-owl. Facial disc pale buff, with white eye-brows; upperparts buff, streaked with dark brown, feathers edged with pale rufous; scapulars whitish or pale buff; flight-feathers barred dark brown and buff; tail dark brown with 2-4 whitish bars; warm buff below, streaked with dark brown, streaks becoming thinner and sparser on belly and flanks; tarsi unfeathered; talons long and curved; iris bright, pale yellow; bill blackish; feet pale yellow-grey to greenish-yellow. Differs from *K. zeylonensis* in deeper, warmer buff colour below, lacks thin wavy bars on underparts. Juvenile more russet and less white-spotted above, tail with 5-6 whitish bars. Race *aagaardi* paler than nominate; *pageli* strongly tinged red; *minor* small. Voice. Loud "kootookookootook...", ringing "pof pof pof", and musical "to-who-to-who"; also hisses, mews and shrieks.

Habitat. Forest bordering streams, rivers, and lakes; also trees beside rice fields and fish ponds, old plantations, parks and large gardens near wetlands, and mangroves; often close to habitations. Mainly in lowlands and plains, locally up to 1100 m; to over 1600 m in Sumatra.

Food and Feeding. Mostly fish; also frogs, crustaceans, reptiles, large aquatic insects, small mammals (rats, mice) and birds; once a tortoise; also carrion, e.g. crocodile and badger. Forages at night, but frequently emerges from roost in late afternoon. Hunts from perch, swooping to catch fish from water surface; also stands beside or in shallow water to catch prey, and actively searches by walking in water.

Breeding. Lays Dec-May, mainly Jan-Apr; Jul-Apr in Malay Peninsula. Nest in cavity of large tree, or in tree fork, or in old raptor nest, occasionally on rock ledge; frequently among fronds of bird's-nest fern (*Asplenium nidus*). 1 egg, rarely 2 (only 1 chick survives); incubation 28-29 days; fledging c. 45 days.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Status poorly known; uncommon in Thailand; locally uncommon to more or less common in Malay Peninsula and SE Asia; common in Borneo. No recent records from Assam, where presumably rare or extinct. Seems to be fairly adaptable, able to occupy reasonably wide range of wooded and watery habitats. Some persecution locally, mainly in areas with fish ponds.

Bibliography. Andrew (1992), Bucknill & Chasen (1990), Delacour (1947), Delacour & Jabouille (1940), Duckworth & Kelsch (1988), Eates (1939), Glenister (1951), Grimmett *et al.* (1998), Hellebrekers & Hoogerwerf (1967), Higgins (1999), Hoogerwerf (1949a), Horne (1996a, 1996b), Lekagul & Round (1991), Lim Kim Seng (1992), MacKinnon (1988), MacKinnon & Philipps (1993), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Meyer de Schauensee & Ripley (1940), Nazimuddin (1993), Riley (1938), Ripley (1982), Rutgers & Norris (1972), Smythies (1981, 1986), Stepanyan (1995), Wells (1999).

Genus *NYCTEA* Stephens, 1826

90. Snowy Owl

Nyctea scandiaca

French: Hârfang des neiges **German:** Schnee-Eule **Spanish:** Búho Nival
Other common names: Snow Owl

Taxonomy. *Strix scandiaca* Linnaeus, 1758, Lapland.

Affinities uncertain. Probably closest to *Bubo*, but generically distinct on basis of skull characters and DNA. Monotypic.

Distribution. Breeds from W & N Scandinavia E across N Russia and N Siberia, including Novaya Zemlya, to Chukotskiy Peninsula. Anadyrland, N Koryakland and Commander Is; then North America in W Aleutians (Attu and Buldir), Hall I in Bering Sea, and from W Alaska E through N Canada to

N Labrador, including Banks, Prince Patrick and N Ellesmere Is; also N Greenland. Has bred occasionally in Iceland and N Britain (Shetland Is).

Descriptive notes. Male 55-64 cm, 700-2500 g; female 60-70 cm, 780-2950 g. Large white owl with small eyes, rudimentary ear-tufts normally invisible. Male entirely white, or with narrow, sparse, pale grey or brown barring on back, wings and/or tail; tarsus and toes with thick white feathering; iris brilliant golden-yellow, at times almost orange, eyelids blackish-edged; bill horn-black, nearly concealed by feathering; claws horn-coloured to black. Female noticeably bigger, crown spotted dark, moderate to extensive barring above and below, wings and tail more prominently barred blackish, but variable, sometimes almost male-like. Juvenile dark mouse-brown, feathers tipped and speckled greyish-white, barred; immature male like adult female, immature female even more heavily barred. Voice. When disturbed, a repeated "kre" call, uttered in flight; female may produce a loud, intense whistling or mewing note, during such situations as coition; when excited, male may utter low, rapid, and repeated cackling "ka"; female produces a higher pitched but similar "ke" note; also, male makes a loud, booming "hoo, hoo," usually double, but sometimes numbering six or more, the last often the loudest, and 1-2 second intervals after each. Male song a loud, booming "goo, goo", usually 2 notes but sometimes up to 6 or more, the last often loudest; female higher-pitched, notes often disyllabic; alarm a rapid, repeated cackling "kre-kre-kre..."; female also produces loud, intense whistling or mewing notes.

Habitat. Open tundra from near tree-line to edge of polar seas, with hummocks, rocks or other low prominences, and sparse low vegetation and dwarf shrubs and lichen; locally also coastal fields and open moorland, and will also use lowland salt meadows and poorly drained freshwater meadows; in general, breeds in areas with plentiful supply of arctic or subarctic rodents, usually at elevations below 300 m, except in Norway (where lemmings occur only on mountains at 1000 m or higher). In winter, also marshes, fields and dunes.

Food and Feeding. Lemmings (*Lemmus*, *Dicrostonyx*) and other voles (*Microtus*, *Clethrionomys*) major food items, at times probably exploited exclusively; other prey taken according to availability, include other mammals to size of hares, birds to size of ptarmigans (*Lagopus*), ducks and medium-sized geese, occasionally fish, amphibians, crustaceans and beetles. In Fennoscandia, of 2700 identified prey items, about a third were lemmings, and most (50-6%) were voles; in Shetland Is, where lemmings and voles absent, fed on rabbits or, when those rare, on chicks of various wading birds. In non-breeding season, mainly small mammals and birds, and some carrion; in British Columbia, grebes (mostly *Podiceps*) and ducks comprised 80% of prey by weight; in NE USA, where mammals abundant, rats and mice 35%, snowshoe hares 20%, and passerine birds 10% of diet. Most active at dusk and dawn, but forages throughout day in summer; on Baffin I, hunts in all weathers and at all hours during continuous summer light, seemingly less around noon and midnight; details of activity during winter darkness uncertain. Hunts from perch, making low, often long flight to capture prey on ground; acute vision and hearing enables it to locate lemmings beneath snow; takes birds also from water's surface, or pursues them in air; sometimes hovers; also pounces while standing or walking; said to catch fish while lying lengthwise belly down on rock by water hole. Small prey eaten whole, head first; larger ones first torn into pieces; birds sometimes partly plucked.

Breeding. Season May-Sept. Monogamous, often pairs for life; occasional polygyny and polyandry. Nest a shallow scrape on ground, usually in slightly elevated site (e.g. hummock, boulder) providing good view; territory c. 3-4 km² but highly variable according to food abundance, can be much larger when prey scarce. Undulating courtship flight by male a series of flaps followed by glide with wings held in dihedral. Clutch size varies with food supply, 3-5 eggs when limited, 7-11 when plentiful, average in Finnish Lapland 7-74; eggs laid at 2-day intervals; incubation 31-33 days, by female, fed on nest by male; chick with greyish-white down; young brooded and fed by female, male delivers food to nest; young can walk outside nest at 14 days, most remain a few days longer, leave at 20-28 days still unable to fly; first attempts at flight at age of c. 35 days, fly well after 50 days, cared for by parents for at least further 10 weeks. Success very variable, even among neighbouring pairs; in Canada, 1 nest produced 11 young from 11 eggs, another 4 young from 10 eggs; in ideal conditions can be very high, e.g. 31 fledglings from 32 eggs in Canada; success dependent on food supply and timing of spring thaw, nesting aborted where food scarce; main causes of nestling mortality starvation, and chilling. First breeding probably at 2 years. Longevity 10 years or more in wild; captive bird lived at least 28 years.

Movements. Mostly migratory and nomadic; some remain in breeding area all year if conditions allow. Movements not predictable, related in ways not fully understood to abundance of prey species; thought to vary considerably from region to region across polar tundra, and intensity of movements fluctuates annually; Nearctic populations periodically irruptive, many or most leaving breeding areas when lemming numbers crash. Winters irregularly S to C & SC USA, N & C Europe, NC Russia, NW & NE China and Japan, occasionally farther S; on average, immature males winter farthest S, adult females farthest N, with adult males and immature females in between. Vagrants recorded as far S as Bermuda and Azores.

Status and Conservation. Not globally threatened. CITES II. Generally uncommon to scarce. In North America, overall status presumed little changed; however, unpredictability of species' prey-dependent breeding densities and wintering distribution make such statements of doubtful value and impossible to test. Many apparently die from starvation during movement S from arctic regions; in examination of specimens in Alberta, however, 45% had moderate to heavy fat deposits, and only 14-1% believed to have starved; in that study, traumatic injuries were major cause of mortality, including collisions with unknown objects (46-5%), automobiles (14-1%), utility lines (4-2%) and airplanes (1-4%), also gunshot wounds (12-7%), electrocution (5-6%), and entanglement in fishing tackle (1-4%). In N Europe believed to have declined, but no real information on any long-term trends; rarity may be due to humans as much as to contraction of arctic habitats; in N Scandinavia, breeding density 40-55 pairs/100 km² in one peak lemming year, but only 15 pairs/100 km² in next peak year; species no longer breeds in Shetland and rarely does in Iceland. No information on N Asian populations. Protective measures prohibit the shooting and trapping of owls for any reason; harvesting of species for food, feathers and claws by native peoples may have local impact on population, but unlikely to have any wider effect on total numbers; policies enacted to protect large birds from electrocution and airplane strikes should benefit this species.

Genus SCOTOPELIA Bonaparte, 1850

91. Pel's Fishing-owl

Scotopelia peli

French: Chouette-pêcheuse de Pel **German:** Bindenfischeule **Spanish:** Cárabo Pescador Común
Other common names: African Fishing-owl/Fish-owl

Taxonomy. *Strix peli* Bonaparte, 1850, Ashanti, Ghana. Relationships of genus uncertain. Monotypic.

Distribution. Locally from Senegambia E to Benin, and from Nigeria S across Congo Basin and C Africa to Botswana, Mozambique and NE South Africa; also SE Sudan, Ethiopia, S Somalia, Kenya and Tanzania; status in S Mali, Burkina Faso and S Niger unclear.

Descriptive notes. c. 55-63 cm; wingspan c. 150 cm; female 2055-2325 g. Largest fishing-owl. Round head with long "loose" feathering, no ear-tufts, lacks prominent facial disc; rufous upperparts with fine dusky bars, scapulars with some buff-white, tail with broad dusky bars; paler rufous below, with fine dusky streaks, becoming chevron marks on flanks; tarsus and toes unfeathered; iris dark brown; bill dark grey. Considerable individual variation in colour and barring, some with albinistic or melanistic feathers. Sexes similar, female often paler than male. Juvenile with body and head whitish, washed rufous; as adult at 15 months. VOICE.

Male gives sonorous hoot, usually followed by deep grunt, "hoooommm-hut", audible to 3 km; female may respond with higher hoot followed by double note "hoot-oot".

Habitat. Forested edges of lowland rivers, swamps and lakes, and estuaries; favours large riparian trees with deep cover and shade, also river islands. Sea-level to 1700 m.

Food and Feeding. Mainly fish; also some frogs, crabs and freshwater mussels; occasional large insects. Most fish prey in size range 100-200 g, but up to 2000 g recorded. Normally nocturnal; occasionally emerges during day. Hunts from perch 1-2 m above water, usually shallow, gliding down to snatch prey from surface, rarely submerging partially; sometimes wades into water from bank. Prey probably detected visually, from surface ripples; acoustical cues probably not used (transmission of sound across water-air interface poor), but squeakers, a major item of diet, produce sound by grating their fin bones, may reveal their general location.

Breeding. Lays Oct-Jun, peak Feb-Apr; timed to ensure brood-feeding at period when water level falling and prey concentrated. Monogamous. Nest 3-12 m up in natural cavity in tree, within 200 m of water; territory often quite small. 1-2 eggs, usually only 1 chick surviving; incubation c. 32-33 days, by female, fed by male; chick with white down, brooded and fed by female, food caught by mate; fledges at 68-70 days, remains within parental territory 6-9 months after fledging. In Botswana, 13 pairs made 10 breeding attempts, fledged 5 chicks; 4 of 13 eggs added, eggs and chicks disappeared for unknown reasons; when successful, may not breed in following year.

Movements. Resident; seasonal fluctuations in water levels force some to move to adjacent territories or floodplains.

Status and Conservation. Not globally threatened. CITES II. Common in Congo Basin, in Botswana (Okavango delta), and in swamps of Caprivi Strip in NE Namibia and also those in C Africa; also common locally in Transvaal, e.g. along R Levubu. Appears to be uncommon to rare in rest of range: e.g. in Kenya, known only from R Tana and secluded parts of R Mara; rare and local in W Africa. Overall densities variable. 1 pair/1-10 km of river, depending on number of suitable sites for fishing, nesting and roosting. Variable conditions, with cycles of drought, severely disrupt its normal lifestyle; sometimes forced to forgo breeding, and immatures may have trouble finding suitable stretch of river on which to establish territory; many starve during dry season. Destruction of riverine growth a threat. Damming and silting of rivers can have adverse effect on species, and in some areas water pollution possibly a problem. Further study needed.

Bibliography. Ash & Miskell (1998), Atkinson, Koroma *et al.* (1994), Bannerman (1953), Barlow *et al.* (1997), Benson & Benson (1977), Benson *et al.* (1971), Brooke (1984), Brown (1976, 1977), Campbell (1977), Cheke & Walsh (1996), Claffey (1997), Davey (1978), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgodd *et al.* (1994), Fabian (1988), Field (1998), Fry *et al.* (1988), Gatter (1997), Ginn *et al.* (1989), Giraudoux *et al.* (1988), Gore (1990), Grimes (1987), Harrison *et al.* (1997), Hickman & Berry (1998), Ives (1991), Kemp & Calburn (1987), Kemp & Kemp (1998), Lewis & Pomeroy (1989), Liversedge (1980, 1981, 1982), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Penny (1994), Pickford *et al.* (1989), Pinto (1983), Riddell (1987), Sereech (1999), Short *et al.* (1990), Snow (1978), Steyn (1982, 1984, 1988, 1994c), Thompson (1972), Wilkinson (1999), Woolley (1980), Zimmerman, D.A. *et al.* (1996).

92. Rufous Fishing-owl

Scotopelia ussheri

French: Chouette-pêcheuse rousse **Spanish:** Cárabo Pescador Rojizo
German: Rotrückten-Fischeule

Taxonomy. *Scotopelia ussheri* Sharpe 1871, Fantee, Ghana.

Relationships of genus uncertain. Monotypic.

Distribution. Sierra Leone, Liberia, Ivory Coast and Ghana; possibly also Guinea.

Descriptive notes. 46-51 cm; 1 male 743 g. Head tawny, with no distinct facial disc or ear-tufts; dark rufous above, scapulars with some buff-white; flight-feathers and tail tawny-rufous with narrow dark bars; face and underparts light cinnamon, breast with narrow rufous streaks; tarsus and toes unfeathered; iris dark brown (sometimes erroneously stated to be yellow); bill black; legs and feet light yellowish. Differs from *S. peli* in smaller size, unbarred upperparts, lack of chevron pattern below. Juvenile with light buffy-white body and head; probably gains adult plumage c. 6 months after fledging. VOICE. Deep, dove-like

"ooo", repeated at 1-minute intervals.

Habitat. River and lagoon edges in lowland forest, mainly primary but also secondary forest and degraded habitat, and sometimes plantations; also recorded in coastal mangroves.

Food and Feeding. Little known; catfish found in 1 stomach. Hunts at night, occasionally in afternoon; observed on perch above a stream in high, dark forest, also resting on sandbar.

Breeding. Very little known. Nestlings collected in Sierra Leone suggest only 1 young raised from egg laid Sept-Oct; in Liberia, juvenile still with downy plumage in Mar, immature with mostly adult plumage in Jul. Biology probably similar to that of *S. peli*.

Movements. Probably resident; possibly some local movements, as with *S. peli*.

Status and Conservation. ENDANGERED. CITES II. Restricted-range species; present in Upper Guinea Forests EBA. Population unknown; only 17-20 records during 1870-1983. Reported as fairly common in Sierra Leone (Loma Mts) in 1992; thought not uncommon in Liberia in 1990's; very few records from Ivory Coast (perhaps owing to confusion over voice); only c. 5 records from Ghana; and single record from Guinea. Small number of observations suggests that species is rare, although it may be overlooked because of its elusive nature. Main threats are clearance of mangrove and forest, and river pollution; iron-ore mining has caused severe pollution to R Mano between Sierra Leone and Liberia, and R Yah in Liberia; in addition, young are captured and kept as pets by local inhabitants. Occurs in a few protected areas through its range, including Gola Forest Reserve (Sierra Leone), Sapo National Park (Liberia) and Tai Forest National Park (Ivory Coast). Survey and monitoring of existing population required.

Bibliography. Allport (1991), Allport *et al.* (1989), Atkinson, Koroma *et al.* (1994), Bannerman (1953), Barlow (1998), Bouet (1961), Clark & Mikkola (1989), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Colston & Curry-Lindahl (1986), Demey & Fishpool (1991), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dutton & Branscombe (1990), Field (1998), Fishpool (1994), Fishpool *et al.* (1989), Fry *et al.* (1988), Gartshore (1989), Gartshore *et al.* (1995), Gatter (1988, 1997), Grimes (1987), Hald-Mortensen (1971), Kemp & Kemp (1998), Louette (1974), Mackworth-Praed & Grant (1970), Rand (1951b), Schouteden (1970), Snow (1978), Stattersfield *et al.* (1998), Thiollay (1985), Turk (1998), Wilkinson (1999).

93. Vermiculated Fishing-owl

Scotopelia bouvieri

French: Chouette-pêcheuse de Bouvier **Spanish:** Cárabo Pescador Vermiculado
German: Marmorfischeule

Taxonomy. *Scotopelia bouvieri* Sharpe, 1875, Lopé, Ogowe River, Gabon.

Relationships of genus uncertain. Monotypic.

Distribution. Congo Basin in S Cameroon, Gabon, Central African Republic, Congo, Zaire, and extreme NW Angola; possibly SE Nigeria.

Descriptive notes. 46-51 cm. Head buffy-rufous with black streaks on forehead, no ear-tufts, inconspicuous light rufous facial disc; upperparts dark rufous-cinnamon with fine dark brown vermiculations, scapulars with variable whitish on outer webs; flight-feathers and tail rufous with dark bars; underparts variably creamy to light rufous, with heavy dark brown streaks, undertail unmarked whitish; tarsi and toes unfeathered; iris dark brown; bill pale yellow. Juvenile cinnamon-washed white on body and head, streaked above, finer streaking below, flight-feathers more rufous. VOICE. Croaking hoot followed

by shorter, faster notes, "drook krook ook-ook ook-ook"; duets.

Habitat. Gallery forest fringing large rivers, within primary forest; prefers rivers 10 m or more in width; also smaller rivers, and pools in swamp-forest or temporarily flooded forest; occasionally away from water.

Food and Feeding. Small fish, frogs, crustaceans, fiddler crabs, and small birds and mammals; appears to eat more crabs and crustaceans than other fishing-owls. Nocturnal. Hunts from perch 1-2 m above water.

Breeding. Lays May-Oct; in Zaire probably as late as Nov-Dec. Uses old stick nest of large bird; recorded laying in nest of Spot-breasted Ibis (*Lamprolaima rara*). 1-2 eggs, 1 nestling surviving; incubation and fledging periods unrecorded. Longevity over 27 years in captivity.

Movements. Probably resident; may make similar movements to *S. peli* during periods of drought. **Status and Conservation.** Not globally threatened. CITES II. Little is known about its biology; this may be because of its secretive lifestyle and remote habitat preferences or because it exists in small numbers. However, may be relatively common on large rivers in the Congo Basin. Further study is necessary to quantify its status.

Bibliography. Atkinson, Koroma *et al.* (1994), Bannerman (1953), Brosset & Énard (1986), Busse (1989), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1996), Elgodd *et al.* (1994), Fry *et al.* (1988), Gatter (1988), Kemp & Kemp (1998), Lippens & Wille (1976), Mackworth-Praed & Grant (1970), Pinto (1983), Sargeant (1994b), Snow (1978), Wilkinson (1999).

Tribe STRIGINI

Genus *STRIX* Linnaeus, 1758

94. Spotted Wood-owl

Strix seloputo

French: Chouette des pagodes **German:** Pagodenkauz **Spanish:** Cárabo de las Pagodas
Other common names: Seloputo Owl

Taxonomy. *Strix Selo-puto* Horsfield, 1821, Java.

In the past, names *Strix orientalis* and *Strix pagodorum* have been used for this species, but both considered invalid. Race *wiepeni* previously referred to by the synonym *Surnia whiteheadi*. Three subspecies recognized.

Subspecies and Distribution.

S. s. seloputo Horsfield, 1821 - S Myanmar and C Thailand S to Sumatra (Jambi) and Java.

S. s. baweana Oberholser, 1917 - Bawean I, off N Java.

S. s. wiepeni (Blasius, 1888) - Calamian Is and Palawan, in W Philippines.

Descriptive notes. 45-47 cm; male 1011 g. Rusty facial disc; upperparts dark brown, head and upper neck almost black, lower back russet, entire dorsal surface covered with black-edged white spots, which extend to forecrown; white barring on upperwing-coverts; scapulars white, striped with dark brown; chin buff-colored; throat white with brown edging, sides of neck barred with white; remaining ventral surface white, tinged russet on breast, all barred dark; tarsus feathered white with dark bars; iris dark brown; bill greenish-black; toes grey. Differs from *S. leptogrammica* in much bolder, broader dark brown barring below. Juvenile

prominently barred; immature often with much white above. Race *baweana* smaller, paler, with narrower bars below; *wiepeni* with yellowish-rufous ground colour below. Voice. Deep and forceful "who", usually preceded by rolling "huhuhuhuh", repeated; also described as resonant, rising "beloop" or "hoop-hoong"; deep growling call also reported.

Habitat. Lowland open forest and forest edge, stands of trees near habitation, orchards, suburban and urban parks, and paddyfields; also noted in mangrove forest and open deforested areas. Sea-level to c. 1000 m, mostly below 800 m.

Food and Feeding. Mostly small rodents, small birds and large insects; often takes Tree Sparrows (*Passer montanus*). Still-hunts from perch 2-3 m above ground.

Breeding. Probably Jan-Jun in Malay Peninsula; young fledglings noted in Mar, Apr, Jun and Aug. Nest in tree cavity, 2-18 m up; sometimes on top of bird's-nest fern (*Asplenium nidus*). 2 eggs, occasionally 3.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Reports vary; apparently common in Myanmar; uncommon in Thailand, but said to be more or less common in Peninsular Malaysia, e.g. in Pasoh Forest Reserve; scarce in Java, and only a couple of records from Sumatra. Possibly overlooked as a result of its rather secretive habits, although species seems to occur at naturally low densities.

Bibliography. (1990, 1999).

95. Mottled Wood-owl

Strix ocellata

French: Chouette ocellée **German:** Mangokauz **Spanish:** Cárabo Ocelado

Taxonomy. *Syrnium ocellatum* Lesson, 1839, Pondicherry.

Race *griseocens* intergrades with nominate *ocellata* in N India. Three subspecies recognized.

Subspecies and Distribution.

S. o. griseocens Koelz, 1950 - from base of Himalayas in Pakistan S to about Rajasthan, and E to Bihar.

S. o. grandis Koelz, 1950 - S Gujarat (Saurashtra Peninsula).

S. o. ocellata (Lesson, 1839) - peninsular India.

Apparently resident also in W Myanmar, but race undetermined.

Descriptive notes. 40-48 cm. Facial disc white with concentric black barring, and some rufous-orange mottling; upperparts grey, mottled and vermiculated with reddish-brown, black, white and buff; flight-feathers and tail barred grey-brown and black; throat chestnut and black with white stippling; prominent white collar on neck side; underparts white to golden with narrow blackish cross-bars; tarsus feathered buffish; iris brown; bill horn-black. Juvenile undescribed. Races differentiated primarily on basis of wing length and tone of upperparts: *grandis* and *griseocens* larger than nominate, *grandis* greyer above, *griseocens* paler above. Voice. Main

breeding-season vocalization described as quavering "chuhua-aa"; during other seasons calls consist of single metallic hoot and an occasional screech.

Habitat. Wooded plains, clumps of mango trees, tamarind and banyan groves, densely foliated trees on outskirts of villages and cultivation; confined to lowlands.

Food and Feeding. Rats, mice and other rodents, and small birds up to size of Rock Dove (*Columba livia*); also crabs, lizards, and large insects such as beetles; record of scorpion found in stomach.

Breeding. Lays Nov-Apr, Feb-Mar in N. Nest usually in natural, mostly unlined tree hollow, possibly rarely in old stick nest of other bird. Usually 2 eggs, occasionally 3; no other information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Uncommon in India; no recent records from Pakistan, where extremely rare or possibly even extinct. Status in Myanmar uncertain; said to have been common in SW (Arakan) before 1950's, but no information since then.

Bibliography. Ali (1996), Ali & Ripley (1981), Baker (1934a), Daniels (1997), Grimmett *et al.* (1998), Mahabal & Lamba (1987), Mukherjee (1995), Perumal (1985a, 1985b), Ripley (1982), Roberts (1991), Smythies (1986).

96. Brown Wood-owl

Strix leptogrammica

French: Chouette leptogramme **German:** Malaienkauz **Spanish:** Cárabo Oriental
Other common names: Himalayan Brown Owl/Wood-owl ("*newarensis* group"); Bartels's Wood-owl (*bartelsi*); Malaysian Wood-owl (*maingayi*)

Taxonomy. *Strix leptogrammica* Temminck, 1831, Borneo.

Probably a species complex rather than a single species. N forms living in montane habitats (*newarensis*, *ticehursti*, *laotiana*, *caligata*) larger, with different vocalizations, likely to represent a separate, polytypic species. Race *bartelsi* likewise vocally distinct and living at higher elevations, probably also specifically distinct. In addition, Sri Lankan *ochrogenys* sometimes considered synonymous with *indranei*; *chuseni* possibly synonymous with nominate; *myrtha* and *nyctiphasma* doubtfully distinct from *maingayi*. Additional races described are *connectens* (single specimen from C India), included in *indranei*, and *orientalis* and *shahensis*, both treated as synonyms of *ticehursti*. Fourteen subspecies recognized.

Subspecies and Distribution.

S. l. newarensis (Hodgson, 1836) - Himalayas, from Jammu and Kashmir E to NE India.

S. l. ticehursti Delacour, 1930 - N & C Myanmar E to SE China (NE to Anhui), S to N & W Thailand, N Laos and N Vietnam.

S. l. caligata (Swinhoe, 1863) - Hainan and Taiwan.

S. l. laotiana Delacour, 1926 - S Laos and C Vietnam (Annam).

S. l. indranei Sykes, 1832 - peninsular India.

S. l. ochrogenys (Hume, 1873) - Sri Lanka.

S. l. maingayi (Hume, 1878) - S Myanmar, S Thailand and Malay Peninsula.

S. l. myrtha (Bonaparte, 1850) - Sumatra; also reported from Mentawai Is (possibly this race).

S. l. nyctiphasma Oberholser, 1924 - Banyak Is, off W Sumatra.

S. l. niasensis (Salvadori, 1887) - Nias I, off W Sumatra.

S. l. chuseni Hoogerwerf & de Boer, 1947 - Belitung I, off SE Sumatra.

S. l. vaga Mayr, 1938 - N Borneo.

S. l. leptogrammica Temminck, 1831 - C & S Borneo.

S. l. bartelsi (Finsch, 1906) - Java.

Descriptive notes. 40-55 cm; 500-700 g (*bartelsi*). Whitish to light rufous-brown facial disc with broad black ring around eyes; whitish eyebrows, occasionally with rufous tint; crown dark brown; upperparts lighter chestnut-brown, with some white or pale barring on scapulars and on wings and tail; chin dark brown; throat and underparts white to buffy, breast often brown, all with thin, indistinct brown barring; tarsus fully feathered; iris dark brown; bill greenish-horn. Juvenile light rufous, barred rusty, wings darker with dark rufous bars, underparts pale buff with faint bars. Races vary in size, depth of coloration, and

markings: *indranei*, *ochrogenys* and *maingayi* richer and darker brown, with dark rufous facial disc, more chestnut in *ochrogenys*; *vaga* slightly bigger than nominate, and duller, greyer; *niasensis* smaller, chest bright chestnut; *bartelsi* with more tawny facial disc, dark brown above, pale chin; "*newarensis* group" much larger, facial disc whitish to pale fulvous-brown, large white throat patch, brown chest band. Voice. Brief series of 3-4 short hoots, first ones very soft, last one longer and louder; also deep, 4-syllable "goke-goke-ga-looo" with emphasis on final note; barking "wow wow" alarm call also noted. Race *bartelsi* a distinctive, loud, explosive, forceful, single "hooh", repeated at long intervals; "*newarensis* group" "lo" "to-hooh" not unlike Rock Dove (*Columba livia*).

Habitat. Forest, usually dense and undisturbed, generally avoiding areas of human habitation; in N Indian Subcontinent often evergreen and moist deciduous, generally at 750-2500 m, but also reported up to 4000 m; dense, broadleaved forest at 760-2700 m in Nepal; to 2750 m in China and Taiwan; plains to 1800 m in peninsular India, also densely wooded gardens in Sri Lanka; noted both in montane forest and in open country in Thailand; primary forest in lowlands in Borneo and Sumatra, where recorded at up to 1500 m; undisturbed mountain forest and forest edge in Java.

Food and Feeding. Small mammals, especially rodents but also some shrews, and Javan specimen contained remains of fruit bat (*Cynopterus*) in stomach; also small birds and reptiles, and large insects; some reports of fish being taken. Bird prey apparently more important in N of range, include not only smaller species such as doves and mynas but also some up to size of pheasants; preference for partridges (*Arborophila*, *Bambusicola*) evident.

Breeding. Lays Jan-Mar in S India and Sri Lanka; Feb-Apr in Himalayas. Nest in cavity of tree, sometimes with few feathers added; in Himalayas, also on rock ledge on cliff face, or in cave, or a scrape on ground, generally at base of tree or rock. 2 eggs, occasionally 1; incubation at 1 site 30 days.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Uncommon throughout most of range in Indian Subcontinent, and rare and local in Bangladesh; possibly more common, or locally com-

mon, in Sri Lanka; rare in Java, where ongoing clearance of mountain forest represents a major threat; in rest of range appears to be uncommon to rare, and again suffering from forest destruction. Occurs in several protected areas throughout its range, such as Chitwan National Park (Nepal), Nam Nao National Park and Khao Nor Chuchi Wildlife Sanctuary (Thailand), Way Kambas National Park (Sumatra), Gunung Mulu National Park (Sarawak), Danum Valley Conservation Area (Sabah), Barito Ulu National Park (Kalimantan) and Baluran National Park (Java).

Bibliography. Ali (1996), Ali & Ripley (1981), Ali *et al.* (1996), Deignan (1945), Delacour & Jabouille (1940), Échécopar & Hùe (1978), Grimmett *et al.* (1998), Holmes (1996), Inskipp & Inskipp (1991), Lekagul & Round (1991), MacKinnon & Philipps (1993), Majumdar *et al.* (1992), van Marle & Voous (1988), Medway & Wells (1976), Phillips (1978), Ripley (1938), Ripley (1977, 1982), Roberts (1991), Smythies (1981, 1986), Voous (1988), Wells (1999), Whymper (1906), Zhang Cizu *et al.* (1997), Zhao Zhengjie (1995).

97. Tawny Owl

Strix aluco

French: Chouette hulotte **German:** Waldkauz **Spanish:** Cárabo Común
Other common names: Eurasian Tawny Owl/Wood-owl, Tawny Wood-owl

Taxonomy. *Strix Aluco* Linnaeus, 1758, Sweden.

Probably forms superspecies with *S. butleri*; formerly considered to include latter as race. Geographical limits of races obscure; nominate *aluco* intergrades with *siberiae* and *sylvatica* with *sanctinicolai*. Several additional races named, but considered probably not acceptable because of species' considerable individual variation and polymorphism; populations from Iberia, Asia Minor and Middle East sometimes separated as *clanceyi*, those from SW Russia as *volhyniae*, and those from S Caspian as *obscurata*. Eleven subspecies recognized.

Subspecies and Distribution.

S. a. aluco Linnaeus, 1758 - N & E Europe E to W Russia (Ural Mts), S to Alps, Balkans and Black Sea; intergrades with .

S. a. siberiae Dementiev, 1933 - from Ural Mts to W Siberia.

S. a. sylvatica Shaw, 1809 - Britain, France and Iberia; probably this race also from S Italy and Greece E to W & C Turkey and Middle East; intergrades with *sanctinicolai*.

S. a. mauritanica (Wetherby, 1905) - NW Africa (Morocco to Tunisia).

S. a. willkenskii (Menzbier, 1896) - NE Turkey, Caucasus and NW Iran, E to Turkmeniya.

S. a. sanctinicolai (Zarudny, 1905) - NE Iraq and W Iran.

S. a. harmsi (Zarudny, 1911) - Turkistan.

S. a. biddulphi Scully, 1881 - Pakistan and NW India.

S. a. nivicola (Blyth, 1845) - Nepal E to SE China, S to N Myanmar and N Indochina.

S. a. ma (Clark, 1907) - NE China (Jilin) and Korea.

S. a. yamadae Yamashina, 1936 - Taiwan.

Descriptive notes. 37-39 cm; wingspan 94-104 cm; male average 440 g, female average 553 g (nominate *aluco*). Medium-sized owl with noticeably stocky body, large and round head; plumage polymorphic, with intermediates. Nominant race mostly grey-brown, facial disc generally pale with some darker concentric rings, crown with dark centre bordered by pale bands; upperparts heavily mottled brown with darker shaft streaks, outer webs of outer scapulars and upperwing-coverts with large white or cream spot at tip; underparts streaked dark and with variable thin cross-bars; tarsus and most of toes feathered; iris blackish-brown; bill horn-coloured to pale yellowish; toes grey. Morphs vary mostly in ground colour of plumage, from deep rufous-brown to dark grey: rufous morph rufous-chestnut to rufous-cinnamon above, facial disc deep rufous-cinnamon with contrasting white arcs from above each eye and from lower cheek joining at base of bill; intermediate birds have hindneck and crown buff to pale cream-yellow with broad black streaks, remainder of upperparts buff-brown to grey-brown with less distinct narrow dark bars and vermiculations, and facial disc off-white with grey concentric lines; grey morph pale buff to grey-buff above, sometimes mixed with white on crown and hindneck; dark grey morph has plumage dominated by narrow dense black bars on crown and hindneck, dense dark grey vermiculations on rest of upperparts, and pale grey facial disc with much dark grey barring and mottling. Juvenile paler, plumage noticeably looser, even shaggy, and more finely barred. Races differ in colour and size, but difficult to distinguish owing to large individual variation: *sylvatica* smallest, usually rufous-brown or tawny-chestnut; *mauritanica* larger, wingspan up to 20% greater than nominate and *sylvatica*, always grey-brown; *siberiae* distinctly paler, with much white; *nivicola* largest, longest-winged, more barred than streaked below. **VOICE.** Long, quavering hoot, followed by faint monosyllable, a short pause, and then extended soft tremolo which falls in pitch; during courtship also long trills; also soft "quii" calls probably as contact, and sharp "ke-wick" in excitement or aggression.

Habitat. Open and semi-open forest, woodland, farmland with trees, parks, larger gardens in villages and towns, and tree-lined urban avenues; also rocky areas with sufficient tree and bush cover; avoids large unbroken forest tracts, wetlands and treeless plains, as well as unduly windswept, frosty or arid climates; occurs from fringe of boreal zone through temperate regions and steppe to Mediterranean and related montane zones. For hunting, requires richly structured habitat with plenty of lookout posts, including sparse woodland, clearings, avenues, cemeteries, hedgerows and gardens, especially among mature trees, and with some preference for access to water. Mainly in lowlands, but ranges up to 2350 m in Turkey and to similar altitudes in Turkistan; even to 4250 m in Himalayas, where sometimes lives above tree-line.

Food and Feeding. Small mammals, from small rodents and shrews up to size of squirrels and young rabbits, and small birds up to size of pigeon; also amphibians, reptiles, earthworms, snails, beetles and other insects, occasionally fish; in urban areas, largely birds, small rodents and other prey taken as available; pellets often contain soil and plant remains, and sometimes composed of soft wood or sawdust. In pellet study in England, mice and voles found to constitute 56-4% of prey, and larger mammals 34-7% of diet; in Scotland, wood mouse (*Apodemus sylvaticus*) most commonly taken mammal prey and House Sparrow (*Passer domesticus*) most frequently identified bird prey. Diet shifts from mainly mammals in winter to primarily birds in breeding season, and from small prey to medium-sized (over 30 g) prey; in E Bohemia, fed mainly on *Microtus* voles, but in poor vole years switched to other food. Relative proportions of prey taken considered to reflect availability, rather than food specialization. Chiefly nocturnal, hunting between dusk and dawn; occasionally diurnal. Most prey located by sound. Hunts mostly from perch, turning body occasionally; makes frequent short flights, returning to same perch; glides or drops on to prey, extends

wings on impact to cover or strike prey; where habitat includes open ground, often flies slowly, with frequent intermittent glides, makes zig-zag searches, and hovers; reported to take fish from water surface while in flight, or by wading in shallows. Forages for earthworms by flying down to ground and waiting motionless until it appears to hear a sound, then rotating head and stretching neck, hopping forward, repeating head movements, and finally making 2-3 long leaps with wings partially spread to peck up worm. Bats and large insects also seized in flight. Usually consumes food on elevated perch.

Breeding. Season Feb-Jul; Jan-May in Himalayas. Monogamous, pairs for life; occasionally bigamous. Nest in hole in tree, also in cliff or building; often uses old nest of Magpie (*Pica pica*) or drey of squirrel (*Sciurus*); sometimes in hole in ground or among tree roots; readily accepts nestbox; fidelity to nest-site marked, although occasionally changes if site deteriorates or is disturbed; in Europe, average territory size from 10-12 ha in optimum habitat to 60-70 ha in poor habitat, and vocal responses to intruders found to be largely sex-specific. 2-9 eggs, usually 3-5, laying interval 2-4 days; female incubates and broods, fed by male; incubation 28-30 days; hatching asynchronous, chick with white down; young brooded until 15 days old; fratricide occurs when food short; fledging period 32-37 days, but will leave nest at 25-30 days and hide on nearby branches; independence 3 months after fledging. In Belgian study, of 256 eggs laid 24% did not hatch, of 195 young hatched 94% fledged, average brood size at fledging 2.06, varied depending on vole numbers; in Sweden, mortality in first year of life 71%, in second year 44%, in third year 48%; in Switzerland, mortality in first year 49%, in second and third years 25%. Age of first breeding 1-2 years. Oldest ringed bird 18 years 10 months.

Movements. Resident. Breeding adults remain in territory all year. Juveniles disperse by late autumn, in temperate areas usually within radius of a few km of natal site; in Fennoscandia, dispersal up to 20 km, but once 745 km into Lapland, and individuals disperse in all directions.

Status and Conservation. Not globally threatened. CITES II. Generally common throughout range. European population in mid 1990's estimated at c. 400,000-560,000 pairs, plus substantial numbers (up to 100,000 pairs) in W Russia and up to 20,000 pairs in Turkey; largest numbers in France and Germany, with c. 85,000 pairs in each, and c. 70,000 pairs in Poland and over 50,000 pairs in Spain; good numbers of pairs also in Croatia (20,000-25,000), Latvia (20,000), Sweden (15,000), Greece (15,000) and Belarus (10,000); British population estimated at around 20,000 pairs. Appears to be fairly stable or slightly increasing in C Europe, and possibly decreasing in N & S. In Britain, declined in 19th century through human persecution, but increased over much of that region from c. 1900 to 1930 (and in some areas to 1950), apparently stabilizing in mid 1970's at figure then put at 10,000-100,000 pairs (upper limit regarded as over-optimistic). Some expansion in range in Netherlands and Belgium, aided mainly by maturation of forest. Considered common in C parts of Russia, but less so in N, and scarce in Caucasus. Thought rather uncommon in China. In England, despite wide variations in numbers of prey and of fledged young produced, a studied population of adults remained notably stable; stability was maintained by those young which failed to find a territory either starving or moving outside area, which in most cases led to mortality; regulation of the population studied was thus due to territorial intolerance acting to produce subsequent mortality.

98. Hume's Owl

Strix butleri

French: Chouette de Butler **German:** Fahlkauz **Spanish:** Cárabo Árabe
Other common names: Hume's Wood-owl/Tawny Owl, Desert Owl

Taxonomy. *Asio butleri* Hume, 1878, Omara, Makran Coast, southern Baluchistan.

Probably forms superspecies with *S. aluco*. Formerly treated as conspecific with latter, but clearly different in plumage, eye colour and vocal patterns, and ecology, as well as DNA. Monotypic.

Distribution. E & S Israel, Jordan, Sinai Peninsula and E Egypt (Red Sea mountains), and patchily in Arabian Peninsula (Saudi Arabia, Yemen and Oman); possibly still S Pakistan (Makran Coast), perhaps also S Iran.

Descriptive notes. 30-35 cm; wingspan 95-98 cm; c. 214-220 g. Resembles *S. aluco* in proportions and plumage pattern. White facial disc; crown with dark central band; upperparts light sandy-grey or greyish-yellow with dusky brown spots and streaks; distinct golden-buff collar across top of mantle, extending as wash across chest; scapulars and wing-coverts tipped pale buff or white; light and dark brown bars on flight-feathers and tail; underparts cream-coloured with some dark mottling or thin brown shaft streaks, lightly vermiculated on breast and flanks; tarsi feathered white; iris orange; bill yellowish-brown; toes greyish. Differs from *S. aluco* in smaller size, paler appearance, lack of heavy dark streaking, orange eyes.

Juvenile very pale, barred, with yellowish eyes. Voice. Long soft hoot followed by two shorter double hoots, "hoooo, hoo-u hoo-u", without tremulous character, repeated after a few seconds.

Habitat. Rocky gorges or canyons in semi-desert and desert, usually with water source nearby; also near acacias and palm groves, and sometimes at ruined buildings; occasionally near settlements.

Food and Feeding. Rodents such as gerbils (*Gerbillus*), jirds (*Meriones crassus*) and spiny mice (*Acomys russatus*); also lizards, birds (small passerines), scorpions, and grasshoppers and other insects. Nocturnal and crepuscular. Hunts mostly from perch, often near roads and tracks; also hawks insects in air; probably forages occasionally by walking on ground.

Breeding. Mar-Aug. Nest in cavity or cave in wall of steep gorge. Up to 5 eggs; incubation 34-39 days, by female, but confirmed record of both parents incubating; chick with white down; fledging period 30-40 days.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Israeli population tentatively estimated at 200 pairs in late 1980's; no numerical data from elsewhere. Originally thought to be fairly rare, this based primarily on fact that until middle part of 20th century almost all information on this species was gleaned solely from the type specimen, collected in Pakistan in 1878. Between 1950's and 1970's, more extensive studies carried out in Middle East, and as a result now considered relatively common in Israel. Fragmented distribution possibly misleading; terrain difficult to census. Not recorded in Pakistan since 1920, although region little visited by ornithologists. Main cause of mortality, at least in Israel, appears to be road traffic.

Bibliography. Alfia (1988), Ali & Ripley (1981), Aronson (1979), Beaman & Madge (1998), Brooks *et al.* (1987), Clark & Mikkola (1989), Cramp (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Échécoar & Hüc (1964), Evans (1994), Fry *et al.* (1988), Goodman & Sabry (1984), Goodman *et al.* (1989), Grimmett *et al.* (1998), Heidrich & Wink (1994), Hollom *et al.* (1988), Hüc & Échécoar (1970), Jennings (1977, 1995, 1996), Kemp & Kemp (1998), Leshem (1980, 1981), Mendelssohn (1996), Mendelssohn *et al.* (1975), Mikkola (1983), Paz (1987), Porter, Christensen & Schiermacker-Hansen (1996), Ripley (1982), Roberts (1991), Shirihai (1984, 1996), Snow & Perrins (1998), Steinbacher (1979), Subah (1984), Voous (1988), Wrånes (1998).

99. Spotted Owl

Strix occidentalis

French: Chouette tachetée **German:** Fleckenkauz **Spanish:** Cábaro Californiano
Other common names: Mexican/Mountain Spotted Owl, Mountain Forest Owl (*lucida*)

Taxonomy. *Syrnium occidentale* Xántus de Vesey, 1860, Fort Tejon, California.

May be member of superspecies that includes *S. varia* and *S. fulvescens*. Occasionally hybridizes with *S. varia* in Mexico, where ranges overlap. Race *lucida* very pale, possibly specifically distinct. Three subspecies recognized.

Subspecies and Distribution.

S. o. caurina (Merriam, 1898) - SW Canada (British Columbia), S through W USA Coast Ranges to N California.

S. o. occidentalis (Xántus de Vesey, 1860) - C & S Californian Coast Ranges and W slope of Sierra Nevada, S to N Baja California.

S. o. lucida (Nelson, 1903) - from N Arizona, SE Utah and S Colorado S to N & C Mexico (S to Michoacán and Guanajuato).

Descriptive notes. 41-48 cm; male 520-700 g, female 550-760 g. Medium-sized brown owl; flight slow, quick wingbeats interspersed with gliding. Facial disc large, rounded, brownish, with indistinct concentric circles of darker brown around each eye; upperparts chocolate-brown to chestnut-brown with numerous round, elliptical or irregular white spots; remiges and rectrices dark brown, barred with light brown and white; underparts heavily barred brown and whitish; legs and feet fully feathered; iris almost black; bill yellowish-green. Differs from *S. varia* in smaller size, darker coloration, lack of vertical streaks on abdomen. Juvenile light

brown with dark transverse barring. Race *caurina* darker brown, with smaller white spots and markings; *lucida* lighter brown, with more white on facial disc and upper breast, more and larger white spots. VOICE. A 4-note "whoop hu-hu hoo", by both sexes, female somewhat higher and hoarser; also a hollow whistle, "cooo-weep", ending in upward inflection, mainly by female during breeding; rapid series of loud barking notes, "ow!-ow!-ow!-ow!-ow!", or single barks; apparently able to make fine adjustments to its own call to imitate that of neighbour.

Habitat. Mature coniferous and mixed forest, and wooded canyons; western hemlock (*Tsuga*), Douglas fir (*Pseudotsuga*), redwood (*Sequoia*), Douglas fir/hardwood, evergreen hardwood, pine-oak, ponderosa pine, western red cedar (*Thuja*) and other forest types, including riparian forest, as well as steep, rocky canyons in some parts of range. In one study, 98% of 636 occupied sites were in areas of old-growth forest, or mixtures of mature and old-growth timber, usually with uneven-aged and multi-levelled canopy; all individuals exhibited strong preference for foraging in old-growth conifer forest (at least 200 years old), with younger forest used progressively less, and forest cleared or burned in preceding 20 years used rarely or not at all; of 1600 roost-sites, 90% were in old-growth forest; of 47 nests studied, 90% in multi-layered old-growth forest, and remainder in stands 70-140 years old with scattered older trees. Possible reasons for species' high dependence on old growth include adequate nest-platform needs, broad temperature gradients and widely diverse roosting sites associated with multi-layered canopy, and associated prey-abundance or prey-availability variables. Occurs from sea-level to c. 2700 m.

Food and Feeding. Small and medium-sized mammals, including e.g. northern flying squirrels (*Glaucomys*), wood rats (*Neotoma*), mice (*Peromyscus*), tree voles (*Phenacomys*), voles (*Microtus*, *Clethrionomys*), snowshoe hares (*Lepus*); also birds, including smaller owls; also frogs, reptiles and insects. Nocturnal, although a roosting owl will opportunistically take prey during day. Hunts from perch, often changing perch several times within single night; detects prey by sight or sound, glides or swoops down and pounces on it, capturing with talons; also snatches arboreal prey from limbs or tree trunks; occasionally hawks for insects and bats. Prey killed on ground or nearby perch by severing cervical vertebrae with bill.

Breeding. Season Mar-Jun. Monogamous. Nest in natural cavity or broken top of tree, or pothole or other cavity in cliff or on cliff ledge, or cave entrance; also in mistletoe brooms or debris accumulation; or uses old squirrel drey or abandoned nest of raptor or corvid; once on ground, 1-4 eggs, usually 2; incubation 30 days, by female, fed by male; female leaves nest briefly to defecate, regurgitate pellets, defend against conspecifics, or receive prey from male; chick covered with white natal down; young brooded and fed by female, food brought by male; as nestlings grow older,

female roosts outside but near nest for more extended periods; fledging 34-36 days. In a summary of 14 studies, 0.25 young fledged/pair for females in their first year, 0.29 for females in their second year, 0.82 for females 3 or more years old; juvenile survival low (0.14-0.26), adult survival high (0.83-0.90). Occasionally breeds in first year; majority of pairs do not breed every year, some known not to breed over periods of 5-6 years. Generally long-lived; in Oregon, several ringed individuals at least 16-17 years old.

Movements. Mostly resident, with some short seasonal shifts. Nominate *occidentalis* sometimes makes short-range seasonal movements (range 15-65 km) or undertakes altitudinal migration (descent 500-1500 m), and *lucida* may also migrate (20-50 km) or move to lower or occasionally higher elevations. In Sierra Nevada, migrates Oct-Dec, spring return generally Feb-Mar; some individuals move back and forth between summer and winter ranges during same winter.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Races *caurina* and *lucida* listed as threatened under US Endangered Species Act, *caurina* as endangered in Canada, *lucida* as threatened in Mexico; *occidentalis* listed as species of special concern by state of California. Status of *caurina* based on historic loss of habitat, projected trends in habitat loss, large areas of low abundance, declining trends in survival rates, and failure of existing regulations to protect race; *lucida* considered threatened in USA owing to projected silviculture strategies and failure of existing regulations to protect it; extensive habitat loss has occurred for both races. In general, nest-sites and prey availability probably serve as limiting factors for population, and primary threats to species include extensive loss of habitat through clear-felling of forest and degradation of habitat due to even-aged tree management; in NW USA, habitat loss ranges from 54% to over 99%. Secondary threats to species include urban and suburban expansion, water development in riparian corridors, agricultural development, fuelwood and oak harvest, reservoir development, and mining activities. In USA, recent management plans for *caurina* criticized by scientists as inadequate; while comprehensive in protection of owl habitat, they lack specific details on owl recovery for either public or private land; in Canada, the Canadian Spotted Owl Recovery Team presented a series of options for *caurina*, most of which contain substantial extinction risk. In California, a current plan for nominate *occidentalis* includes protection of all known sites on federal forest land; however, 2 populations declining and others at serious risk because of low population size, and no listing petition to decrease erosion of habitat or reverse decline of populations. US recovery plan for race *lucida* recommends: protection of 243 ha around nest-sites (or roosting areas if nest-site not known); protection of habitat on steep slopes, natural areas and wilderness areas; changes in logging practices in other habitats (primarily to management for uneven-aged stands); and restoration of, as well as restrictions on use of, riparian zones. Evidence exists that forest selectively logged in past can be reoccupied within 40-100 years if residual elements (snags, coarse woody debris, large trees with cavities) present; however, no published data available for demographic stability in these areas. Also, expanding population of *S. varia* a potential threat to present species, both through predation and because of interbreeding.

100. Barred Owl

Strix varia

French: Chouette rayée **German:** Streifenkauz **Spanish:** Cábaro Norteamericano
Other common names: Northern Barred Owl

Taxonomy. *Strix varius* Barton, 1799, Philadelphia, Pennsylvania.

May form superspecies with *S. fulvescens*, possibly also including *S. occidentalis*. Has at times been considered conspecific with *S. fulvescens*, but bigger than nearby populations of latter and with different vocalizations. *S. occidentalis* in Mexico. Four subspecies recognized.

Subspecies and Distribution.

S. v. varia Barton, 1799 - from SE Alaska (possibly) and SW Canada S to N California, E to Nova Scotia, and C & E USA (S to N Texas and North Carolina).

S. v. helveola (Bangs, 1899) - Texas.

S. v. georgica Latham, 1801 - SE USA.

S. v. sartorii (Ridgway, 1874) - mountains of C Mexico (Durango to Oaxaca).

Descriptive notes. Male 48 cm, mean 630 g; female 51 cm, mean 800 g; wingspan 107-111 cm. Rather big owl with large, rounded head. Facial disc grey-white to pale buffy-grey with 4-5 concentric dark rings; crown, neck, chest and most of upperparts brown to grey-brown with narrow buff-white bars; primaries and secondaries barred; tail with 6-7 sharply defined bands of pale brown; belly and flanks buff-white, each feather with broad central stripe of dark brown, undertail-coverts with narrower stripes; tarsus and toes feathered buff-white, marked with numerous but faint bars or spots of brown; iris deep brown; bill pale greenish-

yellow; talons dark horn, deepening to black at tips. Differs from *S. occidentalis* in larger size, streaked (not barred) belly and flanks. Juvenile more red-brown than grey-brown, with buff rather than white barring on hindneck, more pale buff on underparts and on bars of wing and tail. Race *helveola* paler than nominate, especially tail and wings, while *georgica* and *sartorii* considerably darker; all have toes less feathered. Voice. Highly distinctive, far-carrying 9-syllable, 2-phased hoot, transcribable as e.g. "You cook today; I cook tomorrow"; also series of 6-7 barks rising in volume and ending with loud disyllabic hoot; extremely vocal, with shrieks, cries, trills, grumbles and squeaks.

Habitat. Coniferous and mixed deciduous-coniferous forest, usually heavy, mature wood with nearby open country: examples range from thick stands of dense tall pines and hemlock, and well-established hardwood forest, to isolated woodlots with mature and numerous trees, woodland bordering lakes, streams, swamps, marshes or low meadows, and large parks with old trees. In California, found also in coastal redwood (*Sequoiadendron*) and Douglas fir (*Pseudotsuga*) forest. Needs densely foliated trees for daytime roosting, and large trees (at least 50 cm in breast-height diameter) with suitable cavities for nesting; in study in E USA, found to breed significantly closer to forest openings than would be randomly expected, and tended to prefer well-developed understorey and fewer but larger overstorey trees. Apparently can use variety of habitats in both disturbed and undisturbed conditions; will hunt in close proximity to farm buildings, as well as in cities, town dumps and railway yards. From sea-level to upland areas; at 1500-2500 m in Mexico.

Food and Feeding. Mostly small mammals; also birds, fish, reptiles, amphibians and invertebrates; almost without exception, prey that can be swallowed whole. Mammals include e.g. mice, rats, chipmunks, rabbits, bats, moles and opossums; birds include woodpeckers, doves and sparrows, but also crows, domestic poultry and some owl species (*Otus asio*, *Asio otus*); reptiles include tortoises, lizards and snakes; frogs and salamanders known to be taken; also crayfish, scorpions, snails, beetles and grasshoppers. Race *georgica* known to eat young armadillos and baby alligators. Nocturnal, occasionally diurnal. Hunts mostly from perch, flying down on to prey; occasionally hovers; also flushes small birds from their roosts; can strike by sound alone: wades knee-deep in sluggish streams and ponds, snatching prey with the talons and dragging it ashore; occasionally catches bats in flight.

Breeding. Season c. Feb-Aug, depending on region. Monogamous; probably pairs for life. Prefers tree cavity for nest, but will also use abandoned hawk or crow nest, or squirrel drey; in S, nest sometimes between palm fronds; rarely, a scrape on ground; locally, nestboxes used; successful sites used for many years. 2-5 eggs, usually 2-3 (mean 2.41); replacement laid if first clutch destroyed, sometimes third laid if second similarly destroyed; incubation 28-33 days, by female, fed by male; hatching asynchronous; chick covered in fluffy white down; young brooded by female for 3 weeks, may move on to nearby branches at 4-5 weeks, fledge at 6 weeks, cared for by parents for further 2 weeks or more. In one study, 55 broods produced average of 2.02 young. Known to live over 20 years in captivity.

Movements. Mostly resident; more northerly populations sometimes move S, depending on prey availability. In one study, none of 158 ringing recoveries occurred more than 10 km from point of ringing.

Status and Conservation. Not globally threatened. CITES II. Status uncertain; not uncommon locally. Nominate *varia* has expanded W over past 6 decades; now found in W USA and SW Canada, where has successfully colonized a variety of forested and riparian habitats, including old-growth and mature forest; colonization probably facilitated by anthropogenic influences, such as establishment of riparian forest, tree-planting, and creation of mosaic of habitats through logging; expansion could have negative impact on *S. occidentalis* because of potential for hybridization, competition for food and habitat, and predation. Dependent on forest, requires at least some old-growth trees for nesting; has probably suffered in E & SE parts of range, where large stands of mature forest have been lumbered.

101. Fulvous Owl

Strix fulvescens

French: Chouette fauve **German:** Gelbkauz **Spanish:** Cárabo Guatemalteco

Taxonomy. *Syrnium fulvescens* P. L. Sclater and Salvin, 1868, Guatemala.

May form superspecies with *S. varia*, possibly also including *S. occidentalis*. Considered by some to be conspecific with *S. varia*, but differs in vocalizations, morphology and coloration. Monotypic.

Distribution. S Mexico (E Oaxaca and Chiapas), Guatemala, Honduras and El Salvador.

with rhythm "a'hoo a'hoo-hoo a'hoo, hoo"; also single hoots and nasal notes.

Descriptive notes. 38-48 cm. Facial disc pale grey-brown, rimmed dark brown, with short paler eyebrows; crown and upperparts dark brown, coarsely scalloped and spotted with ochraceous-buff; flight-feathers barred buffy and brown; breast buffy with chestnut-brown bars, rest of underparts pale fulvous with broad brown shaft streaks; tarsus and base of toes feathered; iris dark brown; bill bright yellow; toes yellow. Differs from *S. varia* in much smaller size, more rusty upperparts and more tawny underparts. Juvenile ochraceous-buff overall, faintly barred darker above, facial disc brownish. Voice. Loud, barking hoots, often

Habitat. Humid upper tropical and temperate pine-oak forest in mountain zones and cloudforest. Above 1200 m in Honduras; 2200-3100 m in El Salvador.

Food and Feeding. Little information. Diet mainly rodents and insects; also birds, frogs and lizards. Nocturnal; hunts mostly from perch.

Breeding. Young observed in May. Nest in tree hole. 2-5 eggs; incubation 28-30 days, from first egg, by female. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in North Central American Highlands EBA. Considered uncommon to locally fairly common; species poorly known, however, and status difficult to determine with any reliability. Little available information on species' ecology, but deforestation likely to have detrimental and possibly severe effect on its population size. Occurs in El Triunfo Biosphere Reserve, Chiapas, Mexico.

Bibliography. Anon. (1998a), Binford (1989), Howell & Webb (1995a), Land (1970), Monroe (1968), Ridgely & Gwynne (1989), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Thurber *et al.* (1987).

102. Rusty-barred Owl

Strix hylophila

French: Chouette dryade **German:** Brasilkauz **Spanish:** Cárabo Brasileño
Other common names: Brazilian Owl

Taxonomy. *Strix hylophila* Temminck, 1825, Ypanema, São Paulo, Brazil.

Thought probably most closely related to *S. chacoensis* and *S. rufipes*, all having vocalizations very different from other *Strix*, and possibly generically distinct. Monotypic.

Distribution. E & S Paraguay, SE Brazil (from Minas Gerais to Rio Grande do Sul) and extreme NE Argentina (Misiones).

Descriptive notes. c. 35 cm; male 285-340 g, female 345-395 g. Facial disc light rusty-brown with broad concentric brown rings and small white eyebrows; upperparts barred with white, brown and orange-buff, scapulars with whitish outer webs; chest and flanks orangish-buff with dark brown bars, belly whiter with similar barring; tarsus feathered; iris blackish-brown; bill greyish with yellow tip; toes pale yellow. Differs from *S. rufipes* in more orange-brown general tone and less uniformly barred breast and belly. Juvenile mostly buff, with diffuse barring. Voice. Deep grunting "grugruu-grugruugruu", first part sometimes

longer, especially in duet; also rolling "rrrrroo", and long-drawn "i-ew-eh"; similar to that of *S. chacoensis*.

Habitat. Montane and tropical lowland evergreen forest, and temperate forest, usually with dense undergrowth; also secondary growth; found both in forest and forest edge, sometimes close to habitation. Lowlands to at least 1000 m.

Food and Feeding. Small mammals, birds and insects; probably also reptiles and amphibians. Nocturnal. Forages in canopy.

Breeding. Season uncertain; possibly Aug-Oct in S, but said also to lay Dec-mid Mar. Nest a hole in tree. 2-3 eggs; incubation 28-29 days, by female, while male hunts for the pair; chick with white down, at 11 days eyes open and wing feathers begin to grow; male reported to help brood young; leave nest at 32-35 days, independent by 4 months. First breeding at 1 year.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. Generally rare; locally fairly common, e.g. in NE Argentina (Misiones). Major threat appears to be habitat loss, mainly through logging and burning of forest. Because of the scale of such habitat loss in all parts of its range, species should be carefully monitored. Occurs in several protected areas, such as Rio Doce State Park (Minas Gerais) and Aparados da Serra National Park (Rio Grande do Sul) in Brazil, and Iguazú National Park (Misiones) in Argentina.

Bibliography. Belton (1984), Canevari *et al.* (1991), Chebez (1994), Contreras & Contreras (1984), Grummt (1974), Hayes (1995), Lowen, Clay *et al.* (1997), Maurício & Dias (1998), Olog (1968, 1984, 1985), de la Peña (1994), do Rosário (1996), Saibene *et al.* (1996), Schubart *et al.* (1965), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Willis (1992).

103. Rufous-legged Owl

Strix rufipes

French: Chouette masquée **German:** Rotfußkauz **Spanish:** Cárabo Bataraz
Other common names: Chilean Spotted Owl, Patagonian Wood-owl

Taxonomy. *Strix rufipes* King, 1828, Port Famine, Straits of Magellan.

Thought probably most closely related to *S. hylophila* and *S. chacoensis*, all having vocalizations very different from other *Strix*, and possibly generically distinct. Usually considered to include *S. chacoensis* as a race, but differs in plumage, morphology and voice. Race *sanborni* described from single immature specimen, perhaps not acceptable. Two subspecies tentatively recognized.

Subspecies and Distribution.

S. r. rufipes King, 1828 - from C Chile and extreme WC Argentina S to Tierra del Fuego.

S. r. sanborni Wheeler, 1938 - Chiloe I, off SC Chile.

Descriptive notes. 33-38 cm. Compact, with large round head. Facial disc rusty with faint concentric dusky rings, white lores and eyebrows; upperparts dark rufous-brown, narrowly barred and spotted orange-buff and whitish; flight-feathers and tail barred buff; throat white, chin barred; underparts buffy-white, heavily barred with blackish, vent uniform orange-buff; tarsus and toes fully feathered buffish; iris dark brown; bill yellowish. Juvenile warm buff, obscurely barred dusky brown, face tawny, many white freckles on head. Race *sanborni* known only from immature specimen: smaller, eyebrows less

prominent. Voice. A series of 10-12 loud, somewhat nasal and high-pitched notes “ú AU ú ú ú...”, with a bouncing effect, introduced by c. 4 dry and low-pitched “brrrr” notes; very different from that of *S. chacoensis*.

Habitat. Dense, moist forest with mosses and lichens, and older secondary growth; more often found in old-growth forest with canopy cover exceeding 75% and heavy understorey, but also occurs in semi-open forest; typical tree species include *Aextoxicum punctatum*, *Gevuina avellana*, *Nothofagus* and *Podocarpus*, in more open habitats sometimes *Araucaria*. Occurs from lowlands to mountain slopes, to at least 2000 m.

Food and Feeding. Specializes on small arboreal mammals, e.g. arboreal mouse (*Irenomys tarsalis*), long-tailed mouse (*Oryzomys longicaudatus*), scansorial black rat (*Rattus rattus*), also colocolo opossum (*Dracopis australis*) and long-haired mouse (*Akodon longipilis*); less frequently, birds (e.g. Furnariidae), amphibians (e.g. Leptodactylidae) and insects (e.g. Blattidae, Scarabaeidae) recorded in diet. In study in S Chile, mammals comprised 94-7% of prey biomass, with birds of minor importance (1-5%) and amphibians negligible (0-5%); although insects outnumbered mammals in the diet during spring and summer, their biomass contribution was unimportant on year-round basis. Nocturnal. Mainly a sit-and-wait predator; probably takes some prey by hawking.

Breeding. Poorly known. Laying probably from Oct. Nest usually in tree hole, occasionally in old raptor nest, possibly rarely on ground beneath cover; 2-3 eggs.

Movements. Resident. Immatures may wander; recorded from Falkland Is (has possibly bred), and 1 report from South Georgia.

Status and Conservation. Not globally threatened. CITES II. Status uncertain, owing to rather elusive habits. 1986 report described species as once common, but appearing to be declining. In mid 1990's in S Chile, first quantitative study reported 0-13 pairs/km in secondary forest and 0-22 pairs/km in old-growth forest, with species closely associated with stands of old timber; predicted that, as forest continues to disappear through logging, the odds for species' long-term survival would decrease. Occurs in several protected areas throughout its range, such as Nahuelbuta and Cerro La Campana National Parks, Chile, and Tierra del Fuego National Park, Argentina. Further research required.

Bibliography. Canevari *et al.* (1991), Fjeldsá & Krabbe (1990), Grigera & Úbeda (1996), Humphrey *et al.* (1970), Johnson (1967), Martínez (1993), Martínez & Jaksic (1995, 1996, 1997), de la Peña (1994), Sayers (1998d), Stotz *et al.* (1996), Straneck & Vidoz (1995), Woods (1988).

104. Chaco Owl

Strix chacoensis

French: Chouette du chaco

German: Chacokauz

Spanish: Cárabo Chaqueño

Taxonomy. *Strix chacoensis* Cherrie and Reichenberger, 1921, Fort Wheeler, Paraguayan Chaco. Thought probably most closely related to *S. hylophila* and *S. rufipes*, all having vocalizations very different from other *Strix*, and possibly generically distinct. Usually treated as race of *S. rufipes*, but differs in plumage, morphology and voice. Monotypic.

Distribution. Chaco of S Bolivia (Santa Cruz), W Paraguay and N Argentina (S to Córdoba, San Luis and N La Pampa).

Descriptive notes. c. 35-40 cm; male 360-435 g, female 420-500 g. Facial disc white with dense dusky rings and dark rim; crown with white-bordered dark central band; upperparts cold dark brown, heavily barred and spotted with white; flight-feathers and tail prominently barred with rufous; underparts whitish, densely barred dark brown; tarsus and toes fully feathered creamy-buff, often with rusty barring; iris dark brown; bill pale yellowish. Differs from *S. rufipes* in longer wings and tail, much paler and colder appearance. Juvenile very pale, diffusely barred. Voice. Deep croaking song, “crucrucru crawl-crawl”, sometimes with extra

“crucru” in middle, last 2 notes louder; female slightly higher, often duets; also single “crawl” notes, and loud “creh-creh-creh” alarm; voice similar to that of *S. hylophila* and very different from that of *S. rufipes*.

Habitat. Dry chaco woodland, usually with large cacti and thorn scrub; avoids open country; said to prefer areas near water.

Food and Feeding. Small mammals, birds and insects (e.g. beetles); also scorpions, large spiders and centipedes; reptiles also recorded, e.g. blind snakes (*Leptotyphlops*). Nocturnal and crepuscular; forages during twilight hours. Hunts from perch.

Breeding. Poorly known; probably lays in Oct; nest in tree hole. In captivity: 3 eggs, incubation 35 days, hatching asynchronous, young left nest at c. 5 weeks.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. No information on population size; probably uncommon, but can be locally fairly common, e.g. Chancaní Provincial Park, Córdoba. Habitat conversion probably main threat. Requires study.

105. Ural Owl

Strix uralensis

French: Chouette de l'Oural **German:** Habichtskauz **Spanish:** Cárabo Uralense
Other common names: Ural Wood-owl

Taxonomy. *Strix* [sic] *uralensis* Pallas, 1771, Ural Mountains.

Probably forms superspecies with *S. davidi*; usually considered to include latter as a race. Race *liturata* intergrades with nominate *uralensis*. Several additional named races considered inseparable: birds described from Carpathians (*carpathica*) merged with *macroura*; those from L Baikal to W Amurland (*daurica*), from Sakhalin (*itabanae*) and from NE China and Korea (*corensis*) merged with *nikolskii*; those from C Honshu (*nomiyamae*) included in *hondoensis*. Eight subspecies recognized.

Subspecies and Distribution.

- S. u. liturata* Lindroth, 1788 - N Europe and NW Russia (E to about Arkhangel'sk region), S to N Poland, Belarus and middle R Volga.
- S. u. uralensis* Pallas, 1771 - from E European Russia E to Okhotsk coast.
- S. u. macroura* Wolf, 1810 - C & SE Europe (from Carpathian Mts S to Bulgaria, and in W Balkans).
- S. u. yenisseeensis* Buturlin, 1915 - C Siberian plateau.
- S. u. nikolskii* (Buturlin, 1907) - Transbaikalia E to Sakhalin, S to NE China and Korea.
- S. u. japonica* (Clark, 1907) - Hokkaido.
- S. u. hondoensis* (Clark, 1907) - N & C Honshu.
- S. u. fuscescens* Temminck & Schlegel, 1847 - S Honshu S to Kyushu.

whitish to pale grey-brown, streaked dark, vent plain white; tarsus and toes fully feathered; eyes relatively small, iris dark brown; bill yellow. Differs from *S. nebulosa* in smaller size, dark eyes, lack of facial rings. Juvenile facial disc pale, head feathers heavily tipped white, appearing pale-headed; underbody grey, barred brown. Racial variation mostly slight: *liturata* darker than nominate; *macroura* darker still, larger; *nikolskii* tinged brownish; *fuscescens* much smaller, rufous-brown; *japonica* very pale. **VOICE.** Usually fairly silent; male advertising call "Hu-ooo, Hooo hu-HOO-hoo", with c. 15-50 seconds between calls; female similar but much harsher; duets during courtship; also, harsh "craaw" and series of barks.

Habitat. Boreal forest and mixed woodland, with some open areas such as bogs, clearings or small fields; often found near human dwellings, either in use or abandoned, and also pastures; in S of range (C Europe), confined to deciduous woods, especially of beech (*Fagus sylvatica*), in mountain areas. Hunts in forest glades and fringes of woods; in winter also in other open areas, including parkland and occasionally in vicinity of villages. Generally in lowlands; in C Europe breeds at 450-850 m in Slovakia, to tree-line at 1100-1200 m in Carpathians, and to 1600 m in Romania; in Japan to 1600 m in Honshu, Kyushu and Shikoku, only in lowlands in Hokkaido.

Food and Feeding. Mammals, from size of small rodents such as mice and voles (Microtinae), to larger ones such as water voles (*Arvicola*) and young hares (*Lepus*); also birds, from size of finches (Fringillidae) to pigeons (*Columba*) and Black Grouse (*Tetrao tetrix*); occasionally amphibians, lizards and insects; will also take carrion. In Finland, mammals comprised 86% of prey by number and 87% by weight, vast majority being voles (*Microtus*); birds 9% of prey by number and 11% by weight, with passerines the most important; frogs constituted 5% of prey by number. Nocturnal, occasionally diurnal; most active around dusk and just before dawn. Most hunting from perch; probably also uses searching flight; prey detected by sound, can locate rodents under 20-30 cm of snow. Larger prey decapitated before given to nestlings; surplus food stored at or near nest.

Breeding. Season Feb-Jul. Monogamous; 1 known case of polygyny; pairs usually for life, divorce rate less than 3%. Nest in tree hole or hollow stump, sometimes cavity in cliff or building, often in nestbox; sometimes in old nest of raptor (*Accipiter*, *Buteo*, *Pernis*), crow (*Corvus*) or squirrel (*Sciurus*); rarely on ground; no material added; of 250 Finnish nests (1870-1969), 33% in nestbox, 28% in old nest of other species, 28% in stump, 9% in hole in tree, 1% in building, 0.5% on ground and 0.5% on rock face; high nest-site fidelity; large territory, c. 10 km² in ideal habitat. 2-4 eggs, occasionally 1-6, laying interval 1-3 days; incubation 28-34/35 days, by female, fed by male; hatching asynchronous; chick covered in white down; young brooded up to 2 weeks, by female, latter more fierce than male in nest defence; young leave nest at c. 35-40 days, can fly at c. 45 days, remain with parents for further 2-3 months. In Sweden, of 203 eggs, 80% hatched, with most losses due to food shortage causing female to cease incubation, and of 162 young hatched 98% fledged, giving overall productivity of 0.78 young/eggs laid; in Finland, factors affecting lifetime reproductive success thought to be female body size and nest defence, laying dates (more successful early in season), territory quality, prey populations, and snow cover (affecting access to prey). Age of first breeding usually 3-4 years, although individual ringed as nestling laid eggs at 11 months. Longevity record of ringed individual 20 years, but some probably survives longer.

Movements. Mainly resident, even sedentary. Nearly all males and 90-95% of females stay near previous nest-sites, even during least favourable years; in harsh winters, some females move 100-150 km away from territory and, if they survive, sometimes totally change their breeding area; autumn and winter wandering apparently more extensive in W & C Siberia. Young disperse Sept-Nov; in Finland, two-thirds of first-year birds dispersed within 30 km of natal site, although up to 200 km recorded.

Status and Conservation. Not globally threatened. CITES II. European population estimated at c. 11,000-14,000 pairs (excluding Russia) in mid 1990's, including 4000 in Finland, 4000 in Sweden and 2500 in Estonia; surprisingly high maxima elsewhere, e.g. 2000 pairs in Latvia, 1200 pairs in Belarus, and 1000 pairs in Romania where formerly thought rare. Modern forestry practice of removing old trees and chimney-like stumps a severe threat in Fenno-Scandia, causing decrease in

population, but provision of thousands of nestboxes has led to recovery and even increase; in S Finland current density up to 6-7 pairs/100 km² usual, but in optimum habitat up to 10 pairs/100 km²; considered relatively stable in Fenno-Scandia, but without such artificial sites will probably decline in the future. No reliable data from rest of range, but Russia probably holds substantial population; in former USSR, some fluctuation reported, with earlier decreases in Belarus (1967) and Bashkiriya (1979). In Japan, considered a fairly common resident, although at apparently low density. Population levels partly dependent on food supply, as shortages, especially of small mammals, inhibit breeding (and can provoke irruptive movements). Across range of nominate *uralensis*, reproduction runs fairly parallel to cyclic fluctuations of voles; after hatching, vole abundance perhaps less crucial since declining vole populations compensated for by increased predation on returning migratory birds; breeding success largely regulated by vole availability in winter and early spring; also, clutch size can be partly explained in terms of food limitation.

106. Sichuan Wood-owl

Strix davidi

French: Chouette du Sichouan **German:** Sichuankauz **Spanish:** Cárabo de Sichuán
Other common names: Pere David's Owl/Wood-owl

Taxonomy. *Syrnium davidi* Sharpe, 1875, Mupin, Sichuan.

Probably forms superspecies with *S. uralensis*; usually treated as conspecific with latter on basis of vocal similarities, but separated by morphological differences and geographical isolation; further study needed. Monotypic.

Distribution. C China: SE Qinghai and W & C Sichuan.

Descriptive notes. c. 58 cm. Facial disc with indication of dark concentric rings, and distinct dark border; upperparts rich brown, mottled with blackish-brown, grey and white, greater coverts tipped white and with broad black subterminal bar; flight-feathers and tail barred brown and dusky; breast and belly heavily streaked with black-brown; iris brown; bill pale yellow. Differs from *S. uralensis* in darker appearance, with markings much darker and better defined than any race of latter. Juvenile undescribed. **VOICE.** Long, quavering hoot; barking "khou-khou"; also harsh "ke-wick".

Habitat. Coniferous and mixed forest with

adjacent open areas, from 4000 m to 5000 m.

Food and Feeding. No information.

Breeding. No information.

Movements. Resident.

Status and Conservation. **VULNERABLE.** CITES II. Restricted-range species; present in West Sichuan Mountains EBA. Apparently rare, but no quantitative data on population. Occurs in Jiuzhaigou Reserve, Sichuan. Threatened by extensive deforestation occurring within its range. Further research urgently required.

Bibliography. Beaman (1994), Cheng Tsohsin (1987), Collar *et al.* (1994), Etchécopar & Hue (1978), Inskipp *et al.* (1996), Meyer de Schauensee (1984), Stattersfield *et al.* (1998), Wang Sung (1998), Zhao Zhengjie (1995).

107. Great Grey Owl

Strix nebulosa

French: Chouette lapone **German:** Bartkauz **Spanish:** Cárabo Lapón
Other common names: Dark Wood-owl; Lapland Owl/Striped Owl, Lapp Striped Owl (*lapponica*)

Taxonomy. *Strix nebulosa* J. R. Forster, 1772, northwestern Ontario, Canada.

Affinities uncertain. Population from Kentei Mts, in N Mongolia has been separated as *elisabethae*, but doubtfully separable from *lapponica*. Two subspecies recognized.

Subspecies and Distribution.

- S. n. nebulosa* J. R. Forster, 1772 - North America, from C Alaska E to SW Quebec, S to EC California, N Idaho and NE Minnesota.
- S. n. lapponica* Thunberg, 1798 - Eurasia, from Fenno-Scandia E to W Koryakland, S to Lithuania, N Mongolia, NE China and N Sakhalin.

Descriptive notes. 59-69 cm; male c. 800-1175 g, female 925-1700 g. Large owl, with big rounded head and small, "staring" eyes; slow, deep wingbeats in flight. Facial disc large, circular, light grey with 6 or more concentric rings of darker grey or brown, with whitish eyebrows and lores, and black chin with white at sides; upperparts dark grey to grey-brown, fading with age to brown, with transverse mottling of greyish-white and dark, and some dark streaks; wings and tail barred dark and light grey; underparts greyish with faint vermiculations, broadly streaked with dark grey; tarsus and toes thickly feathered grey; iris and bill yellow. Juvenile cryptic grey and white. Race *lapponica* often somewhat paler than nominate, underparts whiter and more clearly streaked, vermiculations very faint. **VOICE.** Series of low, evenly spaced "hoou" notes, deep and booming, accelerating and dropping slightly near end; female higher-pitched, hoarser; this call typically given most frequently during breeding and near nest; also low, soft double hoots, possibly contact call associated with territorial defence.

Habitat. Dense boreal or coniferous forest, favouring areas with openings; taiga interspersed with sphagnum bogs, muskeg or open fields; pine and fir forest adjacent to montane meadows; and tamarack, black spruce and aspen forest. Outside breeding season occasionally occurs in other habitats, too, sometimes near habitation. Forages mostly at forest edge or in open areas with clear view. Sea-level to c. 1000 m; in California to 2400 m. In Utah to 3200 m.

Food and Feeding. Small mammals, especially rodents; also birds up to size of grouse (Tetraonidae), and frogs and large insects. During breeding, largely voles (*Microtus*).

which often form 90% or more of diet; other mammals include mice, squirrels and hares, and shrews often taken in winter; recorded killing Sharp-shinned Hawk (*Accipiter striatus*). Nocturnal and crepuscular, sometimes diurnal. Hunts from perch, listening and watching ground; after detecting prey, flies up to 100 m to strike. Can detect prey beneath snow by sound alone; will hover, plunge face downward, break through snow cover with "clenched" feet, and grab prey with feet and talons; able to break through snow crust hard enough to support an 80-kg weight, and as deep as 45 cm. Small mammals swallowed whole; larger prey pulled into pieces.

Breeding. Season Mar-Jul in North America; Mar-Aug in Europe. Monogamous; occasional polygyny suspected; pair-bond not maintained over winter, but may nest with same mate in subsequent year if prey populations remain high; pairs form as early as Jan, or as late as 2 weeks prior to laying. Lays in abandoned nest of other bird of prey, or on broken tree snag, sometimes on mistletoe broom, or rarely in shallow depression at foot of tree; also uses artificial platforms; no material added; territory size variable depending on food and site, 0.5-25 km². Male sometimes performs aerial displays, 2-9 eggs, usually 3-5, depending on food supply, laying interval 2 days; clutch sometimes replaced if first lost; incubation c. 28-36 days, by female, fed on nest by male, females leaving very occasionally and briefly to defecate and regurgitate pellets; hatching asynchronous; chick with whitish-grey down; young leave nest at 25-30 days, unable to fly, readily climb leaning trees and roost off ground, capable of flight 7-14 days later; after fledging, young fed directly by male. In NE Oregon, of 67 nesting attempts monitored, 78% fledged young; in Idaho and Wyoming 70-5%, in Manitoba and Minnesota 81%; in Oregon, probability of juvenile surviving first year 0.53, first two years 0.3. Age of first breeding most commonly 3 years, rarely 1, occasionally 2. Can be long-lived: female ringed as adult recaptured 13 years later; has reached 27 years in captivity.

Movements. Resident and nomadic; movement patterns variable, stable in some areas and/or years, highly irruptive in others, influenced by prey availability. Both altitudinal and latitudinal movements occur. Birds probably move also to avoid deep snow, although known to winter well N (as well as S) of its taiga breeding range in Russia. Irrupts into areas with abundant food supply (voles), occasionally breeding in such places well outside normal range. In North America, wanders S to NE Wisconsin and N Michigan; in Europe, has reached N Germany and Ukraine. When migrating, can occur in loose concentrations, probably in response to abundant prey.

Status and Conservation. Not globally threatened. CITES II. Populations fluctuate widely, but generally scarce, with food supply likely critical factor regulating numbers: in Sweden, numbers of pairs breeding vary from 0 to 100 or more in any year, with highest total nests recorded 76 in 1981; in Finland after late 1930's, apparently almost extinct for over 20 years, but since mid 1960's population in peak years several hundreds of pairs, following 3- to 4-year rodent cycle. Population of Europe (excluding Russia) in "normal" years estimated at 500-1500 pairs in 1990's; in Finland minimum of 850 pairs, but possibly 1000-1600 pairs in good vole years. In Russia, marked fluctuations, often scarce: 1 pair/km linear density in Arkhangelsk area; typically 0.05-0.1 birds/km² in Komi Republic, but 0.3 birds/km² in peak vole year; mean overall density in Perm region found to be as low as 0.3 pairs/1000 km²; said to be common in E Siberia. Extremely rare in China. North American population estimated at minimum of 50,000 individuals. Potential threats identified in North America include timber-harvesting, which reduces number of large-diameter trees (live and dead) for nesting, leaning trees used by juveniles for roosting before they can fly, dense canopy closures used by juveniles for cover and protection, and perches required for hunting; also, collisions with automobiles a major cause of mortality in some years; strychnine poisoning of pocket gophers potential harmful; development of campgrounds and associated disturbances may have eliminated species' hunting areas in Yosemite National Park, in California; grazing could reduce prey populations; forestry, peat extraction and agriculture possible threats to preferred habitats in Manitoba. Provision of artificial nest structures (wire baskets or wooden platforms with sticks placed on top) enhances local breeding, with success 83% on artificial platforms versus 66% at natural sites (old stick nests); also allows occupation of new habitats, suggesting that nest-sites a key limiting factor. In USA, known nest-sites protected from logging (National Forest Service land); in some areas, recommended management guidelines include restricted harvest unit size, retention of hunting perches in cut-over areas, and irregularly shaped harvest units (Manitoba and Minnesota). Modified forest management could also enhance habitat by opening up dense forest stands.

108. African Wood-owl

Strix woodfordii

French. Chouette africaine **German:** Afrikanischer Waldkauz **Spanish:** Cárabo Africano
Other common names: Woodford's Owl

Taxonomy. *Noctua Woodfordii* A. Smith, 1834, Knysna, Cape Province.

This species, along with Neotropical *S. virgata*, *S. nigrolineata*, *S. huhula* and *S. albitarsus*, sometimes placed in separate genus *Ciccaba* on basis of differences in external ear structure compared with *Strix*, but DNA studies show that generic separation not warranted. Birds from Sokoke Forest in Kenya sometimes separated as *sokokensis*; populations described from Central African Republic to Sudan and S Zaire (as *bohndorffi*) considered not separable from other races. Four subspecies recognized.

Subspecies and Distribution.

S. w. nuchalis (Sharpe, 1870) - Senegambia E to S Sudan and Uganda, S to N Angola and Zaire (except S & E), including Bioko I.

S. w. umbrina (Heuglin, 1863) - Ethiopia and SE Sudan.

S. w. nigricantior (Sharpe, 1897) - S Somalia, Kenya, Tanzania, Zanzibar and E Zaire.

S. w. woodfordii (A. Smith, 1834) - S Angola and S Zaire E to SW Tanzania, S to N Botswana and the Cape.

Descriptive notes. 30-36 cm; wingspan 80 cm; male 240-270 g, female 285-350 g. Medium-sized owl with large, round head. Buff facial disc, darkest around eyes, prominent white eyebrows; rest of head dark rufous-brown, spotted with white; upperparts dark rufous-grey, spotted and streaked white and buff, scapulars with white outer webs; flight-feathers and tail barred; breast rufous with thin white bars, rest of underparts barred rufous and white; tarsus feathered buff, barred brown; iris dark brown, eyelids red; bill yellow; toes yellowish. Juvenile paler rufous with white bars, facial markings less pronounced; indistinguishable from adult by 5 months. Races

separated by tone of russet colour and by amount of barring on breast: *nuchalis* brightest russet, broadest white chest bars; *nigricantior* more blackish; *umbrina* more brown, with more extensive white barring below. **Voice.** Series of rapid hoots, "who-who who-uh-uh who-oo", first part louder, rest in varying rhythms; female higher-pitched; also high "wheow" by both, male and female; sometimes duets.

Habitat. Woodland and forest, from dense montane forest to bush and riparian areas, coastal forest and lowland rainforest; also inhabits plantations. From sea-level to 3700 m.

Food and Feeding. Varied diet: mainly insects, including katydids, grasshoppers, crickets, cicadas, mantises, cockroaches, moths and caterpillars; also reptiles, frogs and birds, the last including kingfishers (Alcedinidae) as well as small passerines; also small mammals, e.g. rodents and shrews. Nocturnal; occasionally seen by day. Hunts by dropping on to prey from low perch, often 1-2 m from ground; occasionally catches insects in flight, or gleans them from vegetation.

Breeding. Lays Jul-Oct, peak in Sept; Oct-Feb in W Africa. Nest in natural cavity or broken tree top, 2-30 m above ground, usually 2-4 m; rarely at base of tree, under log in leaf litter; 2 accounts of using old nest of goshawk (*Accipiter*); same site re-used even if pair-members change; territory small, c. 50 ha, defended vigorously, 1-3 eggs, usually 2, laying interval 2-4 days; incubation c. 31 days, by female, fed by mate; hatching asynchronous; chick with white down; nestlings brooded by female continuously for 3 weeks, female then helps male in hunting; young leave nest at 30-37 days, sometimes earlier, stay near nest in shelter, can fly at c. 46 days; young remain within parental territory up to 4 months, sometimes do not leave until onset of next breeding cycle, when parents evict them. Genets (*Genetta*) suspected nest predators; pairs with early failures may re-lay.

Movements. Resident.
Status and Conservation. Not globally threatened. CITES II. Commonest owl of forest and woodland throughout whole of sub-Saharan Africa. Occurs in a considerable number of protected areas in most countries throughout its extensive range. No known threats, although habitat destruction could possibly be a problem locally; often seen on roadsides after dark, so some traffic casualties likely.

Bibliography. Allen & Ballantyne (1980), Ash & Miskell (1998), Bannerman (1953), Barlow *et al.* (1997), Benson & Benson (1977), Benson *et al.* (1971), Carlyon & Meakin (1986), Cave & Macdonald (1955), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Cunningham-van Someren (1975), Dean & Macdonald (1971), Delpont *et al.* (1998), Dowsett (1990), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Field (1998), Fry *et al.* (1988), Gatter (1997), Ginn *et al.* (1989), Grimes (1987), Harrison *et al.* (1997), Harvey (1977), Haugaard (1996), Hockey *et al.* (1989), Kemp & Calburn (1987), Kemp & Kemp (1989, 1998), Lambour & Steyn (1986), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Manson (1982), Marchant (1948), Nieboer & van der Paardt (1977), Pakenham (1979), Penry (1994), Pickford *et al.* (1989), Pinto (1983), Scott (1980), Short *et al.* (1990), Snow (1978), Steyn (1982, 1984, 1994a), Steyn & Scott (1973), Vernon (1980), van der Weyden (1972), Zimmerman, D.A. (1972), Zimmerman, D.A. *et al.* (1996).

109. Mottled Owl

Strix virgata

French: Chouette mouchetée **German:** Sprenkelkauz **Spanish:** Cárabo Café
Other common names: American Wood-owl

Taxonomy. *Syrnium virgatum* Cassin, 1849, Bogotá.

This species, along with *S. nigrolineata*, *S. huhula*, *S. albitarsus* and sometimes Afrotropical *S. woodfordii*, often placed in separate genus *Ciccaba* on basis of differences in external ear structure compared with *Strix*, but DNA studies show that generic separation not warranted. W Colombian birds sometimes separated as race *minuscule*. Seven subspecies recognized.

Subspecies and Distribution.

S. v. squamulata (Bonaparte, 1850) - W Mexico (Sonora to Guerrero and Guanajuato to Morelos).

S. v. tamaulipensis Phillips, 1911 - NE Mexico (S Nuevo Leon and Tamaulipas).

S. v. centralis (Griscom, 1929) - E & S Mexico to W Panama.

S. v. virgata (Cassin, 1849) - E Panama, Colombia, Ecuador, Venezuela and Trinidad.

S. v. macconnelli (Chubb, 1916) - the Guianas.

S. v. supercilialis (Pelzelin, 1863) - NC & NE Brazil.

S. v. borelliana (W. Berton, 1901) - SE Brazil, E Paraguay and NE Argentina (Misiones).

Descriptive notes. 29-38 cm; 175-320 g. Occurs in light and dark morphs, found in drier and humid areas respectively. Light morph with brown facial disc with bold white eyebrows, lores and whiskers; dark brown above with faint whitish barring, scapulars with white outer webs; whitish to pale buff below, mottled dark brown on chest, rest of underparts streaked dark brown; tarsus feathered; iris dark brown; bill yellow-grey to blue-grey; toes grey to yellowish. Dark morph somewhat darker all over, upperparts vermiculated greyish-buff to ochraceous-buff, underparts with deep buff ground colour, some dark-morph individuals very black. Juvenile mostly buffy to cinnamon, barred with dusky above, facial area whitish, bill pinkish; like *Pulsatrix*, has series of immature plumages. Races vary in pattern of markings, those in N parts of range smaller with fine distinct barring above, those in Amazon larger and more reddish-brown: *squamulata* smaller than nominate, more spotted above; *centralis* more barred above; *macconnelli* somewhat barred below; *superciliaris* larger, more rufous; *borelliana* dark, pale

markings more buff. Voice. Common territorial call a series of deep, short, frog-like hoots, "gwho gwho gwho...", increasing in pitch and volume, then decreasing; sometimes single hoot, or 1-3 grunts alone; female call cat-like.

Habitat. Wide variety of forest and thickly edge: tropical rainforest, tropical dry lowland forest, pine-oak woodland, thorn forest, gallery forest, semi-open areas and second growth, coffee and cacao plantations, and areas with scattered trees; often close to towns and villages, even in cities. Sea-level to 2500 m.

Food and Feeding. Varied diet suggests opportunist: large insects such as beetles, cockroaches and grasshoppers; small mammals (*Oryzomys fulvescens*, *Sigmodon hispidus*, *Otiotylomys phyllotis*), also bats; small reptiles, including snakes, salamander, lizards (*Anolis*); also tree frog (*Hyla*); probably some small birds. Strictly nocturnal. Forages along forest edge; hunts from perch; probably takes some insects in flight; sometimes attracted to artificial lights.

Breeding. Lays Feb-Apr in Central America, nest with eggs found in Jun in S Mexico (Oaxaca); lays Feb-May in Colombia, Sept-Nov in S of range; juveniles Feb-Mar in NE Argentina. Nest usually in hole of live tree (*Pimenta dioica*, *Brossium alicastrum*) or palm stub; sometimes uses old nest of another bird. 1-2 eggs; no information on incubation or fledging.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Rather widespread, and considered fairly common to common in some places; reportedly common in S Mexico in lowlands, uncommon in Osa Peninsula (Costa Rica), and fairly common from Panama to Colombia and Venezuela; locally not uncommon in S of range; little information, however, on relative abundance in many places. Occurs in a considerable number of protected areas throughout its extensive range. Ecology fairly unknown for such a common species; needs at least patchy forest. Loss of habitat and further forest fragmentation may affect its population; road casualties not infrequent.

Bibliography. Binford (1989), Bonilla *et al.* (1992), Canevari *et al.* (1991), Gerhardt (1991), Gerhardt, Bonilla *et al.* (1994), Gerhardt, Gerhardt *et al.* (1994), Haverschmidt & Mees (1994), Hayes (1995), Herklots (1961), Hilty & Brown (1986), Howell & Webb (1995a), Land (1970), Lasley *et al.* (1988), Lowery & Dalquest (1951), Meyer de Schauensee & Phelps (1978), Miller (1963), Monroe (1968), Olrog (1985), de la Peña (1994), Ridgely & Gwynne (1989), Rowley (1984), Saibene *et al.* (1996), Schaldach (1963), Sick (1993, 1997), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Tostain *et al.* (1992), Voous (1988), Wetmore (1968a), Wyllie (1976).

110. Black-and-white Owl

Strix nigrolineata

French: Chouette à lignes noires **German:** Bindenhalskauz **Spanish:** Cárabo Blanquinegro

Taxonomy. *Ciccaba nigrolineata* P. L. Selater, 1859, Oaxaca, Mexico.

This species, along with *S. virgata*, *S. huhula*, *S. albitarsus* and sometimes Afrotropical *S. woodfordii*, often placed in separate genus *Ciccaba* on basis of differences in external ear structure compared with *Strix*, but DNA studies show that generic separation not warranted. Forms superspecies with *S. huhula*. Sometimes considered conspecific with latter, but bigger, with significant differences in plumage and voice. Monotypic.

Distribution. C Mexico to NW Venezuela, W Colombia and W Ecuador and extreme NW Peru.

Descriptive notes. 33-45 cm; male c. 435 g, female c. 535 g. Facial disc black with indistinct white-speckled border, eyebrows speckled white; crown blackish, broad white-spotted nuchal band; upperparts sooty-brown; tail thinly banded white; underparts white, all evenly and narrowly barred with dark brown; tarsus feathered whitish with dark bars; iris dark brown; bill yellow; toes orange-yellow. Juvenile face whitish, white closely barred with dark brown above, wing-coverts black with some white barring, below buffy-white with dark bars. Voice. Barking hoots, "hu whoOOO"; also series of 3-5 or more notes, last or penultimate note emphatic, "who-who-WHOW-woh".

Habitat. Humid forest, semi-deciduous and deciduous forest, edges and clearing, gallery forest, tall mangroves, plantations, woodland near rivers or swamps; sometimes near villages. Sea-level to 1200 m in Mexico, to 2100 m in Panama, and to 2400 m in Colombia.

Food and Feeding. Insects, such as coleopterans (most commonly Scarabaeidae), orthopterans (Blattellidae), Tettigoniidae, Curculionidae, Cerambycidae; also small vertebrates, including bats (*Artibeus jamaicensis*, *Myotis nigricans*, *Molossus ater*, *Centurio senex*, *Uroderma bilobatum*), rodents (*Oryzomys fulvescens*), possibly also birds. Nocturnal. Hunts from perch; also takes bats and insects in flight, sometimes near artificial lights.

Breeding. Lays late Mar-May, during dry season. Nest in tree hole, or sometimes among epiphytes (*Phylladendron*, *Tillandsia*) or orchids (*Mormolyca ringens*, *Trigonidium egeronianum*) on large and living trees; said occasionally to use old stick nest. 1-2 eggs.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Considered uncommon to fairly common in Mexico; apparently widely distributed but scarce in Honduras; reported as uncommon to rare in Costa Rica; rare in Panama; very local and rare in Colombia and Venezuela, but regularly recorded at Henri Pittier National Park (Aragua). Probably overlooked. Forest clearance a likely threat; extensive use of pesticides may also affect it.

Bibliography. Anderson *et al.* (1998), Beck (1990), Binford (1989), Blake (1958), Gerhardt, Bonilla *et al.* (1994), Gerhardt, Gerhardt *et al.* (1994), Hilty & Brown (1986), Howell & Webb (1995a), Ibañez *et al.* (1992), Kirwan & Sharpe (1999), Land (1970), McCarthy (1976), Meyer de Schauensee & Phelps (1978), Monroe (1968), Orians & Paulson (1969), Ridgely & Gwynne (1989), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Wetmore (1968a), Willis & Eisenmann (1979).

111. Black-banded Owl

Strix huhula

French: Chouette huhul **German:** Zebrakauz **Spanish:** Cárabo Negro

Taxonomy. *Strix huhula* Daudin, 1800, Cayenne.

This species, along with *S. virgata*, *S. nigrolineata*, *S. albitarsus* and sometimes Afrotropical *S. woodfordii*, often placed in separate genus *Ciccaba* on basis of differences in external ear structure compared with *Strix*, but DNA studies show that generic separation not warranted. Forms superspecies with *S. nigrolineata*. Sometimes treated as conspecific with latter, but differs in size, voice and plumage. Two subspecies recognized.

Subspecies and Distribution.

S. h. huhula Daudin, 1800 - E Colombia, S Venezuela and the Guianas to NE Brazil, S to E Peru, NW Argentina, N Paraguay and E Brazil.

S. h. albomarginata Spix, 1824 - SE Brazil, E Paraguay and NE Argentina (Misiones).

Descriptive notes. c. 34 cm. Facial disc blackish, eyebrows and margins of disc speckled white; entire body blackish-brown, upperparts with very narrow and wavy white bars, underparts with very regular bars that widen slightly downwards; tail black with c. 4 narrow white bars and broader white tip; tarsus feathered, barred; iris orange to brown, possibly related to age; bill and toes orange-yellow. Differs from *S. nigrolineata* in barred crown and upperparts. Juvenile browner, heavily barred. Race *albomarginata* tends to be darker, blacker, with white barring more prominent. Voice. Typical song an ascending series of 4 deep and low-pitched "bht"

notes, followed by a sharp and slightly descending "bUhu" note after a longer pause of c. 1-5 seconds; sometimes sounds very like *S. nigrolineata*, and the two will respond to one another's calls.

Habitat. Humid forest and clearings; also in *Araucaria* forest in S of range. In some areas has adapted to man-made habitats, occasionally found in coffee and banana plantations. From sea-level to 200 m, often to 500 m, rarely reported to 1400 m.

Food and Feeding. Primarily insects, especially beetles, locusts and mantids; some small vertebrates. Nocturnal; forages in canopy.

Breeding. No information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Appears to be scarce throughout entire range; no quantitative figures available. Nominate *huhula* was found to be locally not uncommon in mid 1950's, e.g. in N Argentina, but has declined since then. Occurs in several protected areas throughout its range, such as Amacayacu National Park (Colombia), Imataca Forest Reserve (Venezuela) and Manu National Park (Peru). Because it is essentially a forest owl, species is susceptible to habitat destruction by the transformation of rainforest into monocultures and ranchland. Conservation status perhaps merits re-evaluation.

Bibliography. Boesman (1998), Brooks, Barnes *et al.* (1993), Brooks, Clay *et al.* (1995), Canevari *et al.* (1991), Chebez (1994), Cohn-Haft *et al.* (1997), Eriksen & Amarilla (1997), Fjeldså & Mayer (1996), Haverschmidt & Mees (1994), Hayes (1995), Hilty & Brown (1986), Kirwan & Sharpe (1999), Lowen, Clay, Barnett *et al.* (1997), Lowen, Clay, Brooks *et al.* (1995), Meyer de Schauensee & Phelps (1978), Olrog (1985), Partridge (1956), de la Peña (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992).

112. Rufous-banded Owl

Strix albitarsis

French: Chouette fasciée **German:** Rötelskauz **Spanish:** Cárabo Patiblanco

Taxonomy. *Syrnium albitarse* Bonaparte, 1850, Bogotá.

This species, along with *S. virgata*, *S. nigrolineata*, *S. huhula* and sometimes Afrotropical *S. woodfordii*, often placed in separate genus *Ciccaba* on basis of differences in external ear structure compared with *Strix*, but DNA studies show that generic separation not warranted. Affinities uncertain; seems not to be closely related to other Neotropical *Strix*. Bolivian population sometimes separated as *tertia*. Species name often incorrectly spelled *albitarsus*. Monotypic.

Distribution. Andes from N Venezuela S to W & C Bolivia.

Descriptive notes. 30-36 cm. Mid-sized owl with rounded head and distinctive plumage pattern. Facial disc rufous, becoming blacker around eyes, with prominent buffy-white eyebrows and lores, black chin; rest of head and upperparts blackish-brown, barred and spotted buffy-rufous; flight-feathers and tail barred, primaries notched with rufous on outer web; throat white; chest dark brown, barred and spotted tawny and whitish, forming broad but rather diffuse chest band; rest of underparts with feathers edged silvery-white and with rufous-brown central area, producing large, squarish white spots that give ocellated appearance; tarsus feathered whitish;

iris orange-yellow; bill pale yellow; toes whitish to creamy. Juvenile uniformly buff, with blackish mask, brown eyes. Voice. Fast series of short, deep, deliberate notes, "hu, hu-hu-hu, HOOa", with pause after first note, next 3 quicker, and final note protracted and strongly emphasized, rhythm thus different from those of *S. huhula* and *S. nigrolineata*; repeated at intervals of 8-11 seconds.

Habitat. Humid montane evergreen forest and cloudforest, from c. 1700 m to 3700 m; in Venezuela, found in open areas with scattered trees between forested parts.

Food and Feeding. Diet uncertain; probably insects and small mammals. Nocturnal; also active shortly after dark and before dawn. Forages in canopy.

Breeding. Recently fledged bird found in third week Jun in Colombia; juvenile seen in Aug in Venezuela; no other information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Status uncertain; locally fairly common, but few reliable data. Has been recently recorded along the Mérida-La Azulita road and Páramo de Tamá (Venezuela), near Rio Blanco (Colombia), at Paschoa Forest Reserve and along the Nonomindo and Baeza-Tena roads (Ecuador). Probably adversely affected by cutting of forest habitat. Further study needed.

Bibliography. Baez *et al.* (1997), Fjeldså & Krabbe (1990), Fjeldså & Mayer (1996), Hilty & Brown (1986), Krabbe *et al.* (1997), Meyer de Schauensee & Phelps (1978), Olrog (1968), Ridgely & Gaulin (1980), Stotz *et al.* (1996), Vélez & Velázquez (1998).

Genus *JUBULA* Bates, 1929

113. Maned Owl

Jubula lettii

French: Duc à crinière

German: Mähneule

Spanish: Búho de Crin

Other common names: Akun Scops-owl

Taxonomy. *Bubo letti* Büttikofer, 1889, Passy District, Liberia.Affinities uncertain. Sometimes suggested that genus be merged with Neotropical *Lophotrix*; superficial similarities in appearance and similar ecology, however, probably due to convergent evolution. Monotypic.**Distribution.** Liberia, Ivory Coast and Ghana; and patchily from S Cameroon and N Gabon to E Zaire.**Descriptive notes.** c. 40 cm; 1 female 183 g. Highly distinctive. Elongated crown and nape feathers forming brown and white "mane", merging with bushy brown-and-white ear-tufts; rufous facial disc edged in brown, with contrasting white forehead, eyebrows and lores; mantle and back chestnut, scapulars with black-edged whitish outer webs; wing-coverts brown-rufous with creamy and dark vermiculations; flight-feathers and tail barred rufous and buff; throat white; upper breast light rufous, fading to buff or whitish on belly, with dusky brown streaks; tarsus feathered; iris yellow to orange-yellow; bill pale yellow; toesyellow. Sexes similar, female darker and more heavily patterned. Juvenile head and neck almost white, rest washed buff with faint rufous bars. Voice. Reported as mellow "who", followed after 10-12 seconds by similar but higher-pitched note; this vocalization, however, unconfirmed for present species, possibly made by *Scotopelia bouvieri*.**Habitat.** Lowland rainforest and gallery forest, especially with abundant creepers; reportedly associated with old forest, but little known. Often roosts in creepers.**Food and Feeding.** Little information. Insects such as grasshoppers and beetles possibly most important; green vegetable matter found in stomach of young bird. Small, weak feet and bill suggest incapability of capturing larger vertebrate prey; although birds not known to be taken, frequently mobbed by passerines. Strictly nocturnal; emerges at dusk.**Breeding.** Pair with full-grown young observed at Mt Nimba, in Liberia, in third week Feb; observations in Zaire suggest laying during Mar-May; fledglings seen in late Dec and Jan in Cameroon and Gabon. No other details known.**Movements.** Resident; presumed sedentary.**Status and Conservation.** Not globally threatened. CITES II. Very poorly known; status difficult to assess owing to species' secretive and nocturnal habits, and because of scant information on its biology. Reported as very scarce in Ghana, and rare in Liberia, but probably mainly overlooked; only few Cameroon records; no meaningful data from rest of range. Density estimated at 1 pair/1-1.5 km² of forest, so possibly more common than records suggest. Never recorded outside forest or forest clearings; possibly at some risk from habitat loss through harvesting of timber.**Bibliography.** Bannerman (1953), Brosset & Énard (1986), Christy & Clarke (1994), Clark & Mikkola (1989), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (1999), Dowsett-Lemaire (1992, 1996), Fry *et al.* (1988), Gatter (1988, 1997), Grimes (1987), Kemp & Kemp (1998), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1970), Snow (1978), Stephenson & Newby (1997), Thiollay (1985).Genus *LOPHOSTRIX* Lesson, 1836

114. Crested Owl

Lophotrix cristata

French: Duc à aigrettes

German: Haubenkauz

Spanish: Búho Corniblanco

Taxonomy. *Strix cristata* Daudin, 1800, French Guiana.Genus considered by some to be related to *Otus*, and by others to *Bubo*. Recent studies, however, also suggest that it may have some link with *Pulsatrix*. Superficial resemblance to Afrotropical *Jubula* considered probably due to convergence. Race *stricklandi* possibly specifically distinct. Three subspecies recognized.**Subspecies and Distribution.***L. c. stricklandi* P. L. Sclater & Salvin, 1859 - S Mexico to W Panama and W Colombia.*L. c. wedeli* Griscom, 1932 - E Panama to NE Colombia and NW Venezuela; possibly also N Venezuela (1 specimen from Aragua).*L. c. cristata* (Daudin, 1800) - S Venezuela and the Guianas to N Brazil (W Pará), S through Amazonia to N Bolivia and N Mato Grosso, then W to SW Colombia, E Ecuador and E Peru.**Descriptive notes.** 36-43 cm; 400-600 g. Highly distinctive; polymorphic. Pale morph with facial disc tawny to chestnut, white eyebrows continuing into very long, mostly white ear-tufts; upperparts rather plain buffy-brown to grey-brown, wing-coverts spotted with white; off-white below, darker on breast; tarsus feathered; iris dark brown; bill pale yellow; toes greyish to yellow. Dark morph dark brown above, pale brown below, facial disc dark rufous with blackish border. Juvenile with short ear-tufts, dark facial disc, white body plumage, mixed pattern on wing-coverts. Race *stricklandi* distinct, with blackish face and forehead, dark rufous around eyes, white-edged scapulars; eyes usually yellow-orange. Voice. Deep, emphatic growl, "k.k.k'k'k'kkrrrrr", repeated every c. 9 seconds. Race *stricklandi* shorter "gurr" or "kwarr" at irregular intervals.**Habitat.** Humid forest, tall second growth, gallery woodland and heavy forest; roosts by day in dense vegetation, often low down. Sea-level to 1900 m; reported from cloudforest at 1950 m in Honduras; to 1200 m in Guatemala.**Food and Feeding.** Primarily large insects (beetles, orthopterans, caterpillars); probably some small vertebrates. Strictly nocturnal. Little known of foraging behaviour; perches in gaps and at edges, and along streams.**Breeding.** Lays Feb-May, in dry to early wet season. Nest in tree hole; report of nesting in loft of house. Young thought possibly to accompany parents at least through Sept.**Movements.** Resident.**Status and Conservation.** Not globally threatened. CITES II. Very poorly known, and no reliable quantitative data on population level; considered uncommon to fairly common in

Mexico; rare to fairly common in Costa Rica; rare in Panama and Colombia. Has been recently recorded at Lagos de Montebello and Palenque, Chiapas (Mexico), along the Pipeline road (Panama), at Caura and Imataca Forest Reserve, Bolívar (Venezuela), and near Iquitos (Peru). Information required on population size, ecology and behaviour. Habitat loss and deforestation a likely threat to species, which needs at least patchy forest.

Bibliography. Binford (1989), Bousman (1998), Haverschmidt & Mees (1994), Hilty & Brown (1986), Howell & Webb (1995a), Kirwan & Sharpe (1999), Land (1970), Lentino *et al.* (1984), Meyer de Schauensee & Phelps (1978), Monroe (1968), Orians & Paulson (1969), Ridgely & Gwynne (1989), Sick (1993, 1997), Slud (1960, 1964), Snyder (1966), Stiles & Skutch (1989), Storer (1972), Stotz *et al.* (1996), Thurber *et al.* (1987), Tostain *et al.* (1992), Wetmore (1968a).Genus *PULSATRIX* Kaup, 1848

115. Spectacled Owl

Pulsatrix perspicillata

French: Chouette à lunettes

German: Brillenkauz

Spanish: Lechuzón de Anteojos

Taxonomy. *Strix perspicillata* Latham, 1790, Cayenne.Races *chapmani*, *trinitatis* and *boliviana* poorly differentiated, perhaps not valid. Six subspecies recognized.**Subspecies and Distribution.***P. p. saturata* Ridgway, 1914 - S Mexico (Veracruz and Oaxaca) to W Panama (Pacific Slope to Chiriquí).*P. p. chapmani* Griscom, 1932 - Caribbean slope of Costa Rica through E Panama to Colombia, W Ecuador and NW Peru.*P. p. trinitatis* Bangs & Penard, 1918 - Trinidad.*P. p. perspicillata* (Latham, 1790) - Venezuela, the Guianas, Brazil, and from E Colombia S to N Bolivia.*P. p. boliviana* L. Kelso, 1933 - S Bolivia and N Argentina.*P. p. perspicillata* (Wied, 1820) - E Brazil (Bahia S to Rio Grande do Sul) and Paraguay, probably also NE Argentina (Misiones).**Descriptive notes.** 43-52 cm; 590-980 g. 1050-1250 g (*pulsatrix*). Large owl. Facial disc very dark brown, with prominent white eyebrows and lores; head and neck blackish-brown, rest of upperparts paler, dark brown, flight-feathers and tail barred grey-brown; throat white; underparts pale buff, with broad chocolate-brown breast-band; tarsus and toes feathered; iris bright yellow; bill creamy-yellow. Juvenile with facial disc blackish, body completely white, wing-coverts barred grey-brown; several plumage stages before whiteness lost, can take up to 5 years to reach adult plumage. Race *saturata* darker, more sooty-black on head and mantle, finely barred below; *pulsatrix* with head and back uniform brown, chest band broken in centre, eyes more orange or brownish-yellow. Voice. Deep, descending sequence, "PUP-pup-pup-po" or "PUM-PUM-pum-pum", acceleration; female slightly higher, often duets; race *pulsatrix* slower, without acceleration; juvenile a loud whistle and gruff "juuiiu".**Habitat.** Dense tropical rainforest and edges, savanna woodland and dry forest; also areas with scattered trees, coffee plantations and gallery-forested streams; occasionally to 1500 m. Perches alone or in pairs; often along streams in gallery forest.**Food and Feeding.** Primarily vertebrates: small mammals up to size of opossums (Didelphidae), rabbits (Leporidae), skunks (Mustelidae), and rodents such as *Oryzomys bicolor* and agoutis (*Dasyprocta*, *Myoprocta*); sometimes bats, frogs, small reptiles such as lizards, and birds such as doves (Columbidae), motmots (Motmotidae), jays (Corvidae) and oropendolas (*Psarocolius*); also insects such as grasshoppers, large scarab beetles (Scarabaeidae) and large caterpillars, and small crustaceans such as crabs. Nocturnal. Hunts from perch, taking prey from ground or foliage.**Breeding.** Lays mostly Apr-Jun, in dry season and early wet season; some variation, e.g. Sept-Oct in Panama, Aug in Surinam; young observed in Sept in Costa Rica. Nest in large tree cavity. 2 eggs, rarely 3; incubation by female, c. 5 weeks; usually only 1 chick survives, brooded by female, leaves nest at 5-6 weeks, remains with parents for up to 1 year after fledging.**Movements.** Resident.**Status and Conservation.** Not globally threatened. CITES II. Very local, but often considered fairly common where it occurs. Fairly common to uncommon in Mexico; locally from rare to common (Palo Verde and Santa Rosa National Parks) in Costa Rica; fairly common locally in Colombia. Occurs in a considerable number of protected areas throughout its extensive range. Localized distribution due to forest destruction; needs at least patchy forest for nesting and roosting; habits much as *Lophotrix cristata*, but more tolerant of deforestation than latter. Little information regarding abundance, population ecology or behaviour.**Bibliography.** Belton (1984), Binford (1989), van Bockstaele (1977), Bohmke & Macek (1994), Canevari *et al.* (1991), Contreras *et al.* (1990), Fjeldså & Mayer (1996), Gómez de Silva *et al.* (1997), Haffer (1975),

Haverschmidt & Mees (1994), Hayes (1995), Herklots (1961), Hilty & Brown (1986), Howell & Webb (1995a), Land (1970), Lowery & Dalquest (1951), Meyer de Schauensee & Phelps (1978), Monroe (1968), Olrog (1985), de la Peña (1994), Ridgely & Gwynne (1989), do Rosário (1996), Short (1975), Sick (1993, 1997), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Tostain *et al.* (1992), Wetmore (1968a).

116. Tawny-browed Owl *Pulsatrix koeniswaldiana*

French: Chouette à sourcils jaunes **Spanish:** Lechuzón Acollarado Chico
German: Gelbbrauenkauz
Other common names: White-chinned Owl

Taxonomy. *Syrnium Koeniswaldianum* M. Bertoni and W. Bertoni, 1901, probably from near Puerto Bertoni on the Alto Paraná, Paraguay. Possibly forms superspecies with *P. melanota*. Sometimes treated as conspecific with latter, but morphology and vocalizations differ. Monotypic.
Distribution. E Paraguay, extreme NE Argentina (Misiones), and S Brazil (from Espírito Santo S to Santa Catarina).

Descriptive notes. c. 44 cm. Facial disc brown, encircled by ochre, with white rictal bristles near bill, small white chin patch and creamy eyebrows; uniform dark chocolate-brown above, flight-feathers faintly barred with whitish, tail more prominently barred white; breast dark brown, forming broad, distinct band; belly buff; rest of underparts light ochre, often with slight hint of vermiculations; tarsus feathered; iris brownish; bill yellow-horn; toes greyish. Differs from *P. perspicillata* in ochre and creamy (not white) "spectacles" and facial rim, and smaller size; from *P. melanota* in lack of obvious barring on breast and belly. Juvenile

similar to *P. perspicillata*, but eyes dark, face brown rather than black. **VOICE.** Low, descending sequence of ventriloquial "brrr brrr brrr brrr" or "ut ut ut ut" notes, accelerating and weaker at end; female responds with higher-pitched call.

Habitat. Humid, tropical forest and more open woodland; also *Araucaria*-dominated forest; in S Misiones, Argentina, recorded in degraded and marginal forest. From sea-level to 1500 m.

Food and Feeding. Small mammals, birds and large insects; probably also other small vertebrates. Nocturnal; forages in canopy; hunts from perch.

Breeding. Season uncertain. Nest in tree hole, usually 2 eggs; incubation c. 5 weeks, by female; nestling with white down and dark facial disc; young leave nest at 5-6 weeks, unable to fly; cared for by parents for some months further.

Movements. Probably resident.

Status and Conservation. Not globally threatened, CITES II. Restricted-range species; present in Atlantic Forest Lowlands EBA. Considered relatively rare, or at best uncommon; probably overlooked. Has apparently decreased in Argentina owing to timber-cutting in Misiones, although still regularly recorded and possibly locally not uncommon. In Brazil, occurs in several protected areas,

such as Sooretama Biological Reserve and Itatiaia National Park. Suffers some road casualties. Species should be monitored simply because of scale of habitat loss in its range, and because it is too poorly known to speculate on its true status.

Bibliography. Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez (1994), Hayes (1995), Lowen, Clay *et al.* (1997), Olrog (1968, 1984, 1985), de la Peña (1994), Pereyra (1950), do Rosário (1996), Saibene *et al.* (1996), Schubart *et al.* (1965), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

117. Band-bellied Owl *Pulsatrix melanota*

French: Chouette à collier **German:** Bindenkauz **Spanish:** Lechuzón Acollarado Grande
Other common names: Rusty-barred Owl(!)

Taxonomy. *Noctua melanota* Tschudi, 1844, Peru.

Possibly forms superspecies with *P. koeniswaldiana*. Sometimes considered to include latter as race, but morphology and vocalizations differ. Validity of race *philoscia* uncertain. Two subspecies recognized.

Subspecies and Distribution.

P. m. melanota (Tschudi, 1844) - possibly SE Colombia; E Ecuador, and N Peru to SE Peru.

P. m. philoscia Todd, 1947 - WC Bolivia.

Descriptive notes. c. 48 cm. Facial disc brown, with conspicuous white eyebrows and lores; head otherwise uniform dark brown; upperparts chocolate-brown with few buffy-white spots; flight-feathers and tail with widely spaced, thin white bars; throat brown, with distinct white collar below; upper breast rufous-brown, barred and mottled with buff; rest of underparts white, barred reddish-brown, fading to scattered brown bars on creamy belly; tarsus feathered; iris dark red-brown; bill pale, creamy-yellow; toes light greyish. Distinguished from *P. perspicillata* and *P. koeniswaldiana* in clearly barred underparts. Juvenile undescribed. Race

philoscia possibly larger. **VOICE.** Short, deep trill followed by very fast series of 4-5 popping sounds; several deep, muffled hoots recorded in Peru.

Habitat. Humid tropical rainforest; perhaps also more open woodland locally. Found from lowlands to c. 1600 m, mainly above 700 m.

Food and Feeding. Poorly known. Nocturnal.

Breeding. No information.

Movements. Probably resident.

Status and Conservation. Not globally threatened, CITES II. Very poorly known; considered relatively rare, and very few reliable records, although apparent rarity possibly due partly to species' nocturnal habits and seldom penetrated forest habitats. Has been recently recorded at Coca Falls and along the Loreto road, Ecuador. Single specimen possibly from Colombia, but lacks locality and date. In general, species could be threatened by habitat loss.

Subfamily SURNIINAE

Tribe SURNIINI

Genus *SURNIA* Duméril, 1806

118. Northern Hawk-owl

Surnia ulula

French: Chouette épervière

German: Spereule

Spanish: Cárabo Gavilán

Other common names: Hawk Owl

Taxonomy. *Strix Ulula* Linnaeus, 1758, Sweden.

Relationships uncertain; placed near *Glaucidium*, which with *Xenoglaux*, *Microathene* and *Athene* comprise tribe Surniini, on basis of osteology and DNA. Siberian populations, formerly separated as *pallasi*, included in nominate. Three subspecies recognized.

Subspecies and Distribution.

S. u. ulula (Linnaeus, 1758) - N Eurasia E to Kamchatka and Sakhalin, C Siberia S to Tarbagatay. *S. u. tianschanica* Smallbones, 1906 - C Asia and NW & NE China, possibly also N Mongolia.

S. u. caparoch (P. L. S. Müller, 1776) - Alaska through Canada to Newfoundland, S to extreme N USA.

Descriptive notes. 36-39 cm; wingspan 74-81 cm; male 270-314 g, female 320-345 g. Distinctive owl with long tail, broad head, thick-set body, and blackish, dark brown and white plumage pattern; flight and perching hawk-like, flight straight and unhurried, combining bursts of wingbeats with glides. Facial disc greyish-white, with almost black line from eye dividing at hindcrown to create black band around disc and another down nape side; black band may join with dull black-brown bars across upper breast and almost black chin to complete bold dark outline to face, posing strong contrast to relatively faintly barred white breast;

crown black-brown, thickly spotted white, sides of crown almost fully white; nape black-brown, with few white spots and lateral dusky patches opposing lower nape; mantle and back mostly dark brown; white spots on scapulars, appear as pale panels when wing folded; rump and tail black-brown with dull white bars, most obvious on spread tail; white below, closely and heavily barred black-brown; eyes yellow; bill yellow-horn; legs and toes fully feathered and white. Juvenile upperparts grey-brown (less blackish), less extensively marked white. North American race *caparoch* blacker above, tawny below, particularly on flanks and lower belly; slightly larger *tianschanica* even blacker above, with smaller white marks, somewhat intermediate below. **VOICE.** Male gives rapid, trilling "prullul-lullul" with burbling quality, lasting up to 14 seconds; corresponding call of female shriller, shorter and less sonorous; also harsh chattering "ke-ke-ke-ki" and other short, sharp and trilled calls.

Habitat. Occupies forest tundra and boreal taiga as far as tree-line and ranging S to edge of forest steppe and cultivated land. Seeks ready access to clearings, burnt areas, open peatland or muskeg, dry eminences or ridges, and sparse woodland, including birch, aspen and mixed woods, with some preference for pine (*Pinus*), larch (*Larix*) and stunted *krummholz* trees, especially if terminating in broken-topped stumps or bare branches; avoids dense coniferous forest. In winter in North America, inhabits open heathland and prairies, even perching on haystacks.

Food and Feeding. In breeding season, almost wholly small voles (*Microtinae*), with few small birds and larger mammals; also occasional amphibian, fish or insect. Cannibalism known to occur, adults eating own young. Mammals include but are not limited to voles (*Clethrionomys*, *Arvicola*, *Microtus*); birds up to size of thrushes (*Turdus*), but recorded up to size of Willow Grouse (*Lagopus lagopus*). May eat more birds in winter (up to 90% in Fennoscandia), perhaps taking fewer voles because of lower numbers and snow cover. North American race *caparoch* found to prey on juvenile snowshoe hares (*Lepus americanus*); for owls to breed successfully, hares contributed 40-50% of prey biomass during peak years of hare cycle; in general, hares, as well as squirrels (*Tamiasciurus*, *Spermophilus*), may be critical prey items when vole populations low. In China, diet mainly rats. Diurnal and nocturnal. Hunts from exposed perch; changes from one habitual perch to next; pounces on prey or skims down over ground; hovers frequently; can seize prey in flight; sometimes plunges into snow, hunting by sound.

Breeding. Season c. Mar-Sept. Presumably seasonally monogamous; occasional polygyny; no data available on possible incidence of monogamy persisting more than 1 breeding season. Nest in cavity, hole in trees, top of stumps, or nestbox, occasionally old nest of raptors or crow; no fresh material brought to nest. 6-10 eggs, clutch size sometimes increasing to 8-13 in good vole years; eggs laid at intervals of 1-2 days; 1 brood, with replacements laid after egg loss; female incubates and broods, male brings food to nest and sometimes covers eggs when female away; incubation 25-30 days; young altricial, scramble out on to nearby branches before capable of flight, fledge at 25-35 days; young remain in territory 6-8 weeks, cared for by both parents, which sometimes perform distraction-lure display of disablement type when intruder approaches, flying off with "sree" call, landing on ground or stump, drooping wings, and fluttering and calling on ground for several minutes; young independent at c. 75 days. In Canada, fledging success complete for 8 of 9 broods observed. Sexual maturity at 1 year.

Movements. Dispersive and irruptive; essentially nomadic; dependent largely on prey availability. When voles at normal levels, birds breed and winter in N; when vole numbers crash (usually every 4 years), irruptions occur, many individuals dispersing S, mostly juveniles; also, ringed birds have been recovered both NE and SE of ringing locality, at distances of up to 1860 km. Winters irregularly S to N USA, Kuril Is and C & SE Europe; vagrants of nominate race recorded in British Is and S to Yugoslavia and Romania; vagrants of race *caparoch* to Bermuda, Britain and Canary Is.

Status and Conservation. Not globally threatened. CITES II. Numbers fluctuate markedly with abundance of small rodents. Difficult to assess population status or trends; breeding range far removed from most human population centres; almost impossible to census visually in breeding areas. In Europe, believed to have declined markedly, since more recent periodic invasions in S have been on fairly small scale compared with earlier ones. Even in good vole years, nests are usually several kilometres apart; in Norway, population estimated at 1000-10,000 breeding pairs in mid 1990's, with 1 pair/50 km² typical; in Sweden, population estimated half that of Norway, but in exceptional rodent years (e.g. 1976) up to 10,000 pairs and density may increase locally to 1 pair/5 km². In Finland, population has declined since 19th century, as a result of disappearance of hollow trees and through human persecution; tentative estimate c. 3600 pairs, with marked annual fluctuations from almost absent to fairly common, and with some evidence of recovery since 1960's. In Russia, common in N taiga, numbers fluctuating with rodent populations. Rare in China. In North America, populations likely to have been stable over past 10-100+ years, but trends impossible to quantify owing to remote breeding range, low breeding densities, and erratic distribution and numbers during winter irruptions in inhabited areas. Diurnal habits and lack of fear of humans increase vulnerability. Also in North America, while more than 50% of breeding range is in N forests that are currently non-commercial, forestry activities in that region have expanded since c. 1970. Modification of clear-fell logging practices could enhance habitat; cuts of less than 100 ha, interspersed with forest patches and staggered over time, probably optimal; inclusion of suitable numbers of stumps, snags and trees for perching and nesting would provide year-round habitat. Also, fire suppression reduces availability of suitable nest-sites; population known to hunt and nest in old burnt areas.

Genus *GLAUCIDIUM* Boie, 1826

119. Eurasian Pygmy-owl

Glaucidium passerinum

French: Chevêche d'Europe

German: Sperlingskauz

Spanish: Mochuelo Alpino

Other common names: Pygmy Owl/Owlet, Northern Pygmy-owl(!), Old World Pygmy-owl: European Pygmy-owl (*passerinum*)

Taxonomy. *Strix passerina* Linnaeus, 1758, Sweden.

Sometimes considered to form superspecies with *G. brodiei*, *G. perlatum*, *G. californicum* and *G. gnoma* (including recently separated *G. cobanense* and *G. hoskinsii*), but DNA evidence clearly shows that present species and *G. californicum* are not closely related. Race *orientale* intergrades with nominate in W Siberia and Altai Mts. Two subspecies recognized.

Subspecies and Distribution.

G. p. passerinum (Linnaeus, 1758) - from Scandinavia and mountains of S, C & E Europe E across NW & C Russia and Siberia to Sakhalin and NE China.

G. p. orientale Taczanowski, 1891 - C & E Siberia.

Descriptive notes. 16-17 cm; wingspan 34-36 cm; male c. 50-65 g, female c. 67-77 g. Tiny, small-headed owl with flight bounding and dashing. Dimorphic, with brown and grey morphs and varying sharpness of marks: brown morph predominant in most of range, grey predominant only in C & E Siberia. Facial disc dusky with short, almost white eye-brows; bill dull white; indistinct grey-white half-circles on outer cheeks; eyes small and yellow, appearing close-set; upperparts dark dull brown, spotted white-buff overall; flight-feathers dark brown, narrowly barred white-buff; tail dark brown with narrow but distinct buff-white barring; underparts mostly white, upper breast and sides of chest barred dark brown; underwing-coverts noticeably white, contrasting with dark, faintly barred flight-feathers; legs and toes feathered white. When true size not evident, can be confused with *Aegolius funereus*, but distinguished by small head, lack of scapular spotting, and sharp white bars on rather long and square-cut tail; differs from dark races of *Athene noctua* in lack of bold white spots on scapulars, less white-buff spotting, narrower and relatively longer white-barred tail, and longer bill. Juvenile darker, with dusky brown, unspotted upperparts and wing-coverts, unbarred patches on chest sides, thinner streaks on pale underparts. Siberian race *orientale* has paler upperparts which show purer white and more sharply defined spots; breast and flanks more strongly marked brown.

VOICE. Flute-like "deu", repeated monotonously 5-10 times per 10 seconds; bouts of calling may last several minutes.

Habitat. Open coniferous and mixed forest: found in taiga and montane forest, mainly coniferous, sometimes to tree-line; commonly in forest of silver fir (*Abies alba*). In lowlands at upper and middle latitudes; in temperate zone ranging from 250-300 m in narrow cool and moist ravines to above 1000 m in Alps (highest 2150 m). Overall, mainly in tall forest interior, dominated by conifers and often interspersed with beech (*Fagus*), aspen (*Populus*), birch (*Betula*) and other broadleaved

trees used for nesting. Needs access to clearings, moors, meadows or avalanche pathways. Roosts largely in cover of foliage or by tree trunks.

Food and Feeding. Small mammals, especially voles (*Microtinae*), and small birds. In S Finland, during breeding season, voles comprised 58.7% of diet and birds 39.5%. Mammals also include e.g. shrews (*Sorex*), bats (*Myotis*) and mice (*Micromys*, *Apodemus*). Bird prey rarely larger than finches (*Fringillidae*), but occasionally up to size of full-grown woodpeckers (*Dendrocopos*) and thrushes (*Turdus*). In S Finland, towards end of breeding season, diversity of bird prey and proportion in diet increased, apparently because of reduced availability of small mammals (due to growth of vegetation) and increased availability of birds, especially fledglings: in first half of nestling period, young birds made up 18%, in second half 31%. Primarily crepuscular, occasionally diurnal. Prey located by sight; night vision poor. Relies on surprise; hunts mammals from open perch, dropping or gliding on to prey; hunts birds from concealed perch, snatching from branches or striking from below, and will hunt at birdtables. Strikes small mammals with feet and bites them on snout; birds apparently killed with feet and/or bites to head or neck. Prey carried in foot to concealed place for eating; items for delivery to nest or cache often first decapitated. Birds plucked; all prey eaten piecemeal, intestines rejected. Summer caches are small (1 item) and usually on branches or other open sites; in N Europe, caching peaks in Nov-Jan (200 items recorded) and usually in holes, occasionally nestboxes; large caches made only in years with dry and cold Nov and early Dec; apparently no link with prey availability.

Breeding. Season Apr-Jul. Monogamous; pair-bond lasts 1 season, though sometimes renewed after temporary severance in late autumn; pair-bonding involves alternating fear of and aggression towards mate, with pursuit and attacks occurring. Nest in tree cavity, either natural hole or one excavated by woodpecker; will make use of nestboxes; no material added, but debris may be removed; nest-showing begins 6-8 weeks before laying. 4-7 eggs; replacement clutch probably laid after egg loss; female incubates, broods and feeds young in nest, male hunts during incubation and most of nestling phase; female sometimes stimulates male to hunt by apparent attacks; incubation 28-30 days, beginning with last egg; hatching synchronous; fledging 27-34 days; young fed by parents for c. 4 weeks after fledging, at which point parents drive them out of territory. In W Germany, 57 young fledged from 17 nests, averaging 3.3 per nest; in SE Norway, average number of fledged young per egg 0.52-0.94, result of variations in clutch size (5.8-7.3) and food supply. Age of first breeding 1 year.

Movements. Mainly resident. In winter, may shift to broadleaved mixed woodland with some conifers or to neighbourhood of human settlements, with degree of dispersal higher in N than in C Europe. Irregularly irruptive in N Europe; probably triggered by combination of cold weather and rodent scarcity.

Status and Conservation. Not globally threatened. CITES II. In Fenno-Scandia, breeding densities and numbers fluctuate markedly with weather conditions and rodent cycles: in mid 1990's, estimated number of breeding pairs in Norway 2000-6000, in Sweden 10,000-20,000 and in Finland 5000-7000; highest densities up to 30 pairs/10 km² but varying locally over 100-fold. Finnish estimate of 200-300 pairs in 1958 undoubtedly too low; no evidence of decline in Finland, despite large-scale destruction of old forest. Population fluctuates much less in mountains of C Europe, where probably 4100-7200 breeding pairs with density generally 0.7-4.2 pairs/km². In W Germany, has disappeared from large parts of range, linked to deforestation and resulting changes in ecosystem, such as increase in population of *Strix aluco* at higher elevations. In Black Forest, extinct by 1967; captive-breeding programme begun in 1968, and 150 breeding territories in whole of Black Forest by 1995; in this reintroduction, birds used artificial nests only once, and woodpecker cavities very important for species. E German population fluctuates, probably 120-150 pairs (1980). In E Poland (Białowieża Forest) and Belarus, 1300-2600 breeding pairs; in Austria c. 2000 pairs, with fewer in SE France, Switzerland, N Italy, Slovenia, Czech Republic (some recent increase in S Bohemia), Slovakia, Romania and Ukraine. Small isolated population in Rodopi Mts of Bulgaria, and in 1986 species first found nesting in Greece at 1230 m above sea-level in Vardhousia Óri Mts. Probably over 1000 pairs in Baltic states (Estonia and Latvia), but greatly decreased by mid 1960's in Lithuania and now very rare. Russian population estimated at 10,000-100,000 pairs.

Bibliography. Augst (1990, 1992), Augst & Manka (1997), Axer (1977), Barruel (1950), Beaman & Madge (1998), Bergmann & Ganso (1965), Bergmann & Wiesner (1982), Bringeland (1981), Ceriani (1991), Cramp (1985), Creutz & Zschoke (1992), Crocq (1984), Duquet (1997), Étchécopar & Hüe (1978), Ficker (1990), Flint *et al.* (1984), Forsman (1998), Friedrich (1997), Galeotti *et al.* (1993), Gleixner *et al.* (1992), Gödecke & Rudat (1984), Golodushko & Samusenko (1961), Hagemeijer & Blair (1997), Handrinos & Akriotis (1997), Hormann & Menning (1997), Jakobsen (1978), Jedrzejewska & Jedrzejewski (1993), Kalberer & Kalberer (1980), Källander (1975), Kellomäki (1977), Klaus, Klaus & Bräsecke (1982), Klaus, Kucera & Wiesner (1976), Klaus, Vogel & Wiesner (1965), Kloubec (1992), König (1968, 1977, 1993, 1998), König *et al.* (1995), Korpimäki (1992a), Kullberg (1995), Laferrière (1952), Mattes (1981), Menning (1990, 1998), Mikkola (1983), Missbach (1976), Möckel & Möckel (1980, 1984), Möckel *et al.* (1992), Nadler (1994, 1996), Pacenovsky (1990, 1993), Pfennig (1995), Pühringer (1990, 1992), Rogacheva (1992), Rudat & Gödecke (1997), Rutgers & Norris (1972), Säman (1975), Scherzinger (1970, 1974a), Schöner (1976a, 1976b, 1980), Schulenberg (1992), Schulenberg & Wiesner (1986), Simeonov *et al.* (1990), Snow & Perrins (1998), Solheim (1984a, 1984b), Sonneborn & Daus (1995), Stepanyan (1990), Tonko (1992), Varga (1992), Voous (1988), Wendt (1997), Wiesner (1997a, 1997b), Wiesner & Rudat (1983), Wiesner *et al.* (1992), Ytreberg (1997), Zhao Zhengjie (1995), Zschoke (1982).

120. Collared Owlet

Glaucidium brodiei

French: Chevêchette à collier **German:** Wachtelkauz **Spanish:** Mochuelo Acollarado
Other common names: Pygmy Owl/Owlet, Collared Pygmy Owllet, Collared/Banded Pygmy-owl

Taxonomy. *Noctua Brodiei* Burton, 1836, Simla, Himalayas.

Sometimes considered to form superspecies with *G. passerinum*, *G. perlatum*, *G. californicum* and *G. gnoma* (including recently separated *G. cobanense* and *G. hoskinsii*), but DNA evidence clearly shows that *G. passerinum* and *G. californicum* are not closely related. Four subspecies recognized.

Subspecies and Distribution.

G. b. brodiei (Burton, 1836) - from N Pakistan through Himalayas to SE Tibet, N Indochina, S, C & E China (including Hainan), and S to Malaysia.

G. b. pardalotum (Swinhoe, 1863) - Taiwan.

G. b. peritum (Bonaparte, 1850) - Sumatra.

G. b. borneense Sharpe, 1893 - Borneo.

Descriptive notes. 15-17 cm; male c. 53 g, female c. 63 g. Tiny owl with rounded head, large for size of body. Rufous, chestnut and grey-brown morphs occur. Crown spotted creamy-buff, with staring "dorsal face" on nape; white eyebrows, white throat patch; back, tail and flight-feathers barred dark brown and buff; scapulars tipped white, forming interrupted lines down sides of mantle; breast sides and flanks barred, belly sides streaked; iris golden-yellow; bill greenish-horn; tarsi feathered white; feet greenish-yellow. Resembles a miniature version of the partially

Food and Feeding. Small birds, insects, rodents, lizards and skinks. Relative to size of owl, fairly large birds taken, including adult and nestling barbets (*Capitonidae*), woodpeckers (*Picidae*) and thrushes (*Turdidae*); often takes nestlings. One of most diurnal members of genus; active around dusk and at night, but also hunts all hours of day. Hunts from perch, such as fence post; swoops to catch insects in flight. Holds larger prey with foot while tearing at it with bill. Often mobbed by passerines.

Breeding. May-Jun in Nepal; Apr-May elsewhere in range. Nest unlined tree cavity; often kills woodpeckers or barbets to appropriate nest cavity. Usually 4 eggs (3-6); incubation c. 25 days; eggs hatch asynchronously; both adults feed nestlings.

Movements. Resident; some altitudinal movements suspected.

Status and Conservation. Not globally threatened. CITES II. Common to fairly common over most of range. Occurs in several protected areas throughout its range, such as Khao Yai and Kaeng Krachan National Parks (Thailand), Hsitung Forest Recreation Area (Taiwan), Kerinci-Seblat National Park (Sumatra) and Mount Kinabalu National Park (Borneo); frequently recorded at Fraser's Hill, Peninsular Malaysia. Mainly a forest bird, only occasionally observed near human habitation, so presumably vulnerable to effects of habitat destruction.

Bibliography. Ali & Ripley (1981), Ali *et al.* (1996), Bangs & Van Tyne (1931), Bates & Lowther (1952), Deignan (1945), Étchécopar & Hüe (1978), Glenister (1951), Grimmett *et al.* (1998), Holmes (1996), Hüe & Étchécopar (1970), Inskipp & Inskipp (1991), Lekagul & Round (1991), MacKinnon & Phillips (1993), Madoc (1976), Majumdar *et al.* (1992), van Marle & Voous (1988), Medway & Wells (1976), Riley (1938), Ripley (1982), Roberts (1991), Smythies (1981, 1986), Stepanyan (1995), Voous (1988), Wells (1999), Zhang Cizu *et al.* (1997), Zhao Zhengjie (1995).

121. Pearl-spotted Owl

Glaucidium perlatum

French: Chevêchette perlée **German:** Perlkauz **Spanish:** Mochuelo Perlado
Other common names: Pearl-spotted Owl

Taxonomy. *Strix perlata* Vieillot, 1817, Senegal.

Sometimes considered to form superspecies with *G. passerinum*, *G. brodiei*, *G. californicum* and *G. gnoma* (including recently separated *G. cobanense* and *G. hoskinsii*), but DNA evidence clearly shows that *G. passerinum* and *G. californicum* are not closely related. Population of E & NE Africa sometimes separated as *kilimense*, included in *licua*. Two subspecies recognized.

Subspecies and Distribution.

G. p. perlatum (Vieillot, 1817) - Senegambia to W Sudan; possibly also Liberia.

G. p. licua (Lichtenstein, 1842) - E Sudan, Ethiopia and Uganda S to N & E South Africa, Angola and Namibia.

Descriptive notes. 17-20 cm; wingspan c. 40 cm; male 36-86 g, female 61-147 g. Head cinnamon-brown with off-white facial disc, whitish eyebrows; nape has 2 black patches rimmed and interconnected with white, forming "false eyes"; upperparts also cinnamon-brown, with white spots; flight-feathers dark brown with light rufous bars; relatively long, brown tail showing incomplete white bars; breast and belly white with broad brown streaks, streaking denser on breast; yellow eyes and pale yellow-horn bill. Juvenile less rufous, with fewer spots on mantle and crown, shorter tail. Race *licua* greyer and more heavily spotted than

nominate. **VOICE.** Series of loud whistles rising in pitch and volume to climax of long, loud notes; female higher-pitched than male; vocal mainly after dark, often duetting.

Habitat. Commonest in bushveld and open woodland, but also occurs in grassland, forest and dense woodland.

Food and Feeding. Mainly arthropods; also bats, birds, rodents and lizards. Most diurnal African owl, especially in winter, but hunts mainly at night. Hunts from perch, watching ground for prey; flicks tail when excited or nervous; dives fast to strike; strong, powerful feet capable of killing birds larger than itself, such as doves (*Columbidae*). "False face" most prominent when head cocked forwards to look for prey beneath perch; may serve to discourage predators attacking from behind, or make small birds believe it is looking away, rendering them more vulnerable to surprise attacks. Also chases prey in flight, which is fast and undulating as in woodpeckers (*Picidae*). Once observed pirating food from wood-hoopoes (*Phoeniculus*) as they carried it to nest; suspected of robbing nest holes and eating carrion.

Breeding. Lays Aug-Nov, peak Sept-Oct. Territorial throughout year. Nest in cavity, especially old nest of barbet (*Capitonidae*) or woodpecker, 1.2-10 m above ground; will reuse nest-site; sometimes ravages nests of other species to gain site, but at other times itself usurped by bees or by other birds such as hornbills (*Bucerotidae*), rollers (*Coraciidae*) or starlings (*Sturnidae*). Female sometimes calls to solicit courtship feeding a month before laying, often followed by copulation; also sexes call in duet. 3 eggs (2-4), incubated by female while male feeds; incubation c. 29 days, eggs hatch asynchronously; fledging period c. 31 days; if disturbed at nest, female sits tight and lies flat on nest floor, looking like nest debris and showing "false face". Rarely raises full clutch to fledging; in 8 pairs, none had 100% success; no second broods recorded.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Widespread; locally common to rare in various parts of range. Most commonly observed owl in S Africa, probably as a result of diurnal habits. Less common in upper W edge of range; only report from Liberia was of adult with half-

grown nestling brought to Monrovia Zoo; in Ghana uncommon, confined to woodland savanna. Few records from L. Victoria Basin.

Bibliography. 122. Northern Pygmy-owl

Glaucidium californicum

French: Chevêchette des Rocheuses **German:** Kalifornienzwergkauz **Spanish:** Mochuelo Californiano
Other common names: Californian Pygmy-owl

Taxonomy. *Glaucidium californicum* P. L. Selater, 1857, Calaveras County, California. Sometimes considered to form superspecies with *G. passerinum*, *G. brodiei*, *G. perlatum* and *G. gnoma* (including recently separated *G. cohanense* and *G. hoskinsii*), but DNA evidence clearly shows that present species and *G. passerinum* are not closely related. Formerly treated as race of *G. gnoma*; split on basis mainly of vocalizations, DNA and ecology. Racial differences rather slight, based primarily on morphology; *pinicola* perhaps not valid. Four subspecies recognized.

Subspecies and Distribution.

G. c. grinnelli Ridgway, 1914 - SE Alaska through coastal British Columbia S to coastal W USA (Washington, Oregon, California).
G. c. swarthi Grinnell, 1913 - Vancouver I.
G. c. californicum P. L. Selater, 1857 - British Columbia and Alberta to W USA (S to Nevada and California) and NW Mexico (N Sonora, NW Chihuahua).
G. c. pinicola Nelson, 1910 - W USA (Idaho and Montana S to Arizona and New Mexico, E to Colorado).

Descriptive notes. 16-18 cm; male 62 g, female 73 g (*californicum*). Plump, with round head, short wings and long tail; fairly tame, easily approached; flight undulating, with distinct flapping and gliding. Grey and rufous morphs occur. Facial disc brownish-white, not well defined; upperparts grey-brown with fine whitish spots on head, nape, mantle, scapulars and wing-coverts; back of head shows pattern resembling eyes or face, showing "false eyes" of black centres and white borders and slight suggestion of bill; tail barred thinly white, separated by wider brownish bars; whitish underparts with brownish-black streaks, sides of

chest and flanks brownish, with fine white spotting; eyes yellow, bill whitish-yellow; tarsus fully feathered. Differs from *G. brasilianum* in distinct spotting on head; from *G. minutissimum* in streaking on back; from *Aegolius funereus* and *A. acadicus* in smaller head, indistinct facial disc, and longer tail extending past wings when perched. Sexual dichromatism reported, males averaging greyer than females; needs further study. Juvenile has incomplete spotting on head over eyebrows, little to no spotting on back, dark bill. Races differ slightly in tone of coloration and degree of spotting; *swarthi* very dark; *pinicola* perhaps more spotted. **VOICE.** Usually series of single and evenly spaced "toot" notes, often following staccato sequence; in Colorado, heard to produce extended series of hoots, about 2 per second for periods of up to 20 seconds.

Habitat. Coniferous and deciduous forest and forest edge; in Sierra Nevada of California, extends from blue oak (*Quercus*) savanna habitats in foothills to mixed montane conifer forest, becoming scarce above 1800 m and preferring sites with low to intermediate canopy coverage, such as edges of meadows, lakes and similar clearings. In Arizona, *pinicola* associated primarily with montane coniferous forest. In California, breeding males collected from forest of mature, residual and second-growth pine, especially ponderosa pine (*Pinus ponderosa*), incense cedar (*Calocedrus decurrens*), white fir (*Abies concolor*) and black oak (*Quercus velutina*), ranging from 1200 m to 2190 m in elevation.

Food and Feeding. Small to medium-sized birds, mammals and large insects; to lesser extent, amphibians and reptiles. Mammals include mice (*Microtus*, *Peromyscus*) and shrews (*Sorex*), and birds include grosbeaks (*Coccothraustes*) and swallows (*Tachycineta*); also California Quail (*Callipepla californica*) and red squirrel (*Tamiasciurus*) prey items of interest because of size in relation to that of species; insects include beetles and moths. One study found that sexes ate similar percentages of vertebrate prey (males 85%, females 76%); however, females ate significantly more small mammals than males, which fed more on birds. In Montana, prey deliveries to nest reported to comprise 65% mammals, 32% birds and 3% insects; in only comprehensive study of diet, fed on 36% birds; also, 2 individuals were caught in mist-nets with partially eaten Dusky Flycatcher (*Empidonax oberholseri*), Black-capped Chickadee (*Parus atricapillus*), MacGillivray's Warbler (*Opornis tolmiei*) and Common Yellowthroat (*Geothlypis trichas*). Diurnal and probably crepuscular; activity probably dictated by hunger, prey densities and nesting stage. When hunting, uses perch-and-pounce technique; appears to hunt by sight, but prey location by sound cannot be ruled out; when foraging, will focus on prey and switch tail from side to side in quick, jerky motion (significance unknown), then move closer to prey in zigzag pattern from branch to branch, until dropping straight down on prey. Captives concentrated on breast of birds and ate entire body of small mammals; most prey decapitated; usually half of prey eaten, then other half about 3-6 hours later; will cache and later retrieve food; observed picking and pulling road-killed Pine Siskins (*Carduelis pinus*) off highway and caching in nearby tree; caching may buffer and reduce food shortages during inclement weather, or increase foraging opportunities during activity periods.

Breeding. Season Apr-Aug. Apparent seasonal monogamy; no reports of polygyny. Nest in cavity, usually unlined, though nest cavity in Canada was lined with strip of western red cedar (*Thuja plicata*); recorded nesting with *Aegolius acadicus* in same snag, also with Pileated Woodpecker (*Dryocopus pileatus*); reuse of nest not well known. In courtship, female may solicit male with tooting call, hitherto generally thought to be male behaviour; further study needed. 2-7 eggs; incubation c. 28 days; hatching asynchronous, though some reports suggest more synchronous than in open-nesting strigids; chicks semi-altricial, dependent on female for food and thermoregulation; male feeds incubating and brooding female until nestlings c. 9 days old, when female begins hunting; fledging c. 23 days, all leaving about same time, lending support to suggestion of more synchronous hatching, though further study needed; fledglings observed to roost on same branch 75 m

from nest 8 days after leaving. Age of first breeding probably 1 year. Lifespan and survivorship unknown (no ringing recoveries, despite 318 birds ringed up to 1994).

Movements. Partly resident, also either migratory or wandering. Long-distance movements unknown; local movements apparent in W USA (Rocky Mts); e.g., in W Montana valleys, birds show up Nov and leave Mar; appears to be vertical migrant, but studies needed to confirm this.

Status and Conservation. Not globally threatened. CITES II. Non-significant decline in California; non-significant increase in Oregon; significant decline in interior Rocky Mts (Wyoming, Montana, Idaho, British Columbia and SE Alberta); on larger geographic scale, no significant increase for W USA or North American continent. In Canada, current population size ranges from 2000 to 10,000 pairs. Although much apparently suitable habitat throughout range, much of this unoccupied by species, perhaps indicating that factors beyond prey species important to distribution and abundance. Probably affected by predators, other forms of natural mortality, prey densities and catastrophic events such as weather, among other variables; also, possibility of secondary poisoning via pesticides (organochlorines) must be considered. As forest species and obligate cavity nester, probably vulnerable to some forestry practices and development; habitat alterations affecting cavity-excavators and prey species would be likely to affect species. Not known to use nestboxes. Management suggestions include long-term monitoring, research, defining and maintaining forest habitats, and public education.

Bibliography. Armstrong (1983), Babeock (1993), Bourcious (1987), Bull, Hohmann & Henjum (1987), Campbell *et al.* (1990), Eckert (1974), Gent (1984), Hayward (1983), Hayward & Garton (1988), Heidrich *et al.* (1995a), Heintzelman (1992), Hewkin (1993), Holt & Hillis (1987), Holt & Leroux (1996), Holt & Norton (1986), Holt *et al.* (1990), Howell & Webb (1995a), Johnson (1988), Kaufman (1996), Lundsten (1993), Marti (1986), Munn (1997), Norton & Holt (1982), Price *et al.* (1995), Righter (1995), Root (1988), Small (1994), Stotz *et al.* (1996), Tyler & Phillips (1978), Urban (1959), Voous (1988), Walker (1993), Walsh (1990), Webb (1982a), Wolfe & de la Torre (1990).

123. Mountain Pygmy-owl

Glaucidium gnoma

French: Chevêchette naine **German:** Gnomenkauz **Spanish:** Mochuelo Gnomo
Other common names: Northern Pygmy-owl(!), American/Mexican Pygmy-owl

Taxonomy. *Glaucidium Gnoma* Wagler, 1832, Mexico.

Sometimes considered to form superspecies with *G. passerinum*, *G. brodiei*, *G. perlatum* and *G. californicum*, and including recently separated *G. cohanense* and *G. hoskinsii*, but DNA evidence clearly shows that *G. passerinum* and *G. californicum* are not closely related. Formerly considered to include last 3 as races, but these split on basis of vocalizations and/or DNA evidence. Perhaps closely related to *G. costaricanum*, which has recently been considered conspecific with present species by some authors. Monotypic.

Distribution. From SE Arizona S through interior highlands of Mexico (from Chihuahua and Coahuila S to Oaxaca).

Descriptive notes. 15-17 cm; 54-73 g. Very similar to *G. californicum*. Differs in slightly smaller size, shorter tail, and voice. **VOICE.** Song of "toots" usually given in groups of 2 in series, interspersed with single notes; often starts with rapid sequence of short "hu" notes.

Habitat. Coniferous forest and forest edge in mountain regions, generally above 1500 m; in Arizona, however, typically on S-facing mountain slopes dominated by oaks (*Quercus*).

Food and Feeding. Similar to that of *G. californicum*. Mainly insects, especially beetles, grasshoppers and crickets; also small mammals, birds and reptiles.

Breeding. Season Apr-Aug. Apparent seasonal monogamy; no reports of polygyny. Nest in tree cavity, especially old hole of woodpecker. 2-4 eggs; incubation c. 28 days; hatching asynchronous; male feeds incubating and brooding female until nestlings about 9 days old, when female begins hunting; fledging probably c. 23 days. Age of first breeding probably 1 year; life span and survivorship unknown; no ringing recoveries.

Movements. Presumed resident.

Status and Conservation. Not globally threatened. CITES II. Apparently not uncommon locally. Has been recently recorded at Cerro El Potosi (Nuevo León), Barranca Rancho Liebre (Sinaloa), Volcán de Fuego (Jalisco), Temascaltepec (México), Sierra de Atoyac (Guerrero), and Cerro San Felipe (Oaxaca). Factors affecting populations, and suggestions for management, similar to those for *G. californicum*.

Bibliography. Baichich & Harrison (1997), Binford (1989), Eckert (1974), Heidrich *et al.* (1995a), Heintzelman (1992), Howell & Webb (1995a), Johnson (1988), Kaufman (1996), Root (1988), Schaldach (1963), Stotz *et al.* (1996), Tyler & Phillips (1978), Voous (1988), Walker (1993), Wolfe & de la Torre (1990).

124. Guatemalan Pygmy-owl

Glaucidium cohanense

French: Chevêchette du Guatemala **Spanish:** Mochuelo Guatemalteco
German: Guatemalazwergkauz

Taxonomy. *Glaucidium cohanense* Sharpe, 1875, Cobán, Alta Vera Paz, Guatemala.

Sometimes considered to form superspecies with *G. passerinum*, *G. brodiei*, *G. perlatum*, *G. californicum*, *G. gnoma* and *G. hoskinsii*, but recent DNA evidence clearly shows that *G. passerinum* and *G. californicum* are not closely related. Has usually been considered a race of *G. gnoma*, but separation from latter perhaps currently unwarranted, as vocalizations undescribed. Monotypic.

Distribution. S Mexico (Chiapas), Guatemala and Honduras.

Descriptive notes. 16-18 cm. Bright reddish-brown, with little mottling on head; wings spotted and barred; tail long with 5-8 white bars; rufous streaks below broad, rather diffuse; iris and feet yellow. Occurs also in brown

morph. Juvenile similar to adult, but head grey with forehead more mottled. Voice. No information available.

Habitat. Highland forest.

Food and Feeding. Insects, small rodents and occasionally birds.

Breeding. Little known. Nest in abandoned woodpecker hole; 3-4 eggs.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in North Central American highlands EBA. Little known about ecology and population status. Recently recorded in Mexico, near the towns of Unión Juárez and San Cristóbal de las Casas, Chiapas. Forest destruction possibly a threat.

Bibliography. Anon. (1998a), Heidrich *et al.* (1995a), Howell (1995), Howell & Webb (1995a), Land (1970), Monroe (1968), Ridgely & Gwynne (1989), Stotz *et al.* (1996), Voous (1988), Walters (1993).

125. Baja Pygmy-owl

Glaucidium hoskinsii

French: Chevêchette de Hoskins

Spanish: Mochuelo de Hoskins

German: Hoskinszwegkauz

Other common names: Cape Pygmy-owl

Taxonomy. *Glaucidium gnoma hoskinsii* Brewster, 1888, Sierra de la Laguna, Miraflores, Baja California.

Sometimes considered to form superspecies with *G. passerinum*, *G. brodiei*, *G. perlatum*, *G. californicum*, *G. gnoma* and *G. cobanense*, but DNA evidence clearly shows that *G. passerinum*

and *G. californicum* are not closely related. Formerly treated as race of *G. gnoma*; recently split on basis mainly of vocalizations. Monotypic.

Distribution. S Baja California (Mexico): Sierra Victoria, probably also Sierra de la Giganta.

Descriptive notes. 15-16 cm; c. 50-65 g. Tiny, like *G. gnoma*; apparently monomorphic. Sandy grey-brown overall, averaging redder in female; facial disc brownish, white eye-brows narrow; crown, nape and upperparts grey-brown to rufous-brown, spotted buffy. Juvenile undescribed; probably differs from adult in same way as do *G. californicum* and *G. gnoma*. Voice. Slow double hoots with occasional single hoots; also rapid, slightly quavering "huhuhu", which often precedes bouts of hooting.

Habitat. Pine and pine-oak forest, from 1500-2100 m; descends to 500 m in winter, prob-

ably also to deciduous woodland.

Food and Feeding. Insects and reptiles, as well as small mammals and birds.

Breeding. Little known. Lays May-early Jun; juvenile observed in late Jul. Nest in tree cavity.

Movements. Rare winter visitor Oct-Mar to N Baja California.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Baja California EBA. Considered fairly common. Has been recently recorded in Sierra de la Laguna and at the edge of the small town of Miraflores. Little known about ecology and population status.

Bibliography. Anon. (1998a), Heidrich *et al.* (1995a), Howell & Webb (1995a), Stotz *et al.* (1996), Wilbur (1987).

PLATE 15

126. Costa Rican Pygmy-owl

Glaucidium costaricanum

French: Chevêchette du Costa Rica

Spanish: Mochuelo Costarricense

German: Costa-Rica-Zwergkauz

Taxonomy. *Glaucidium jardinii costaricanum* L. Kelso, 1937, Costa Rica.

Formerly treated as race of *G. jardinii*, but clearly different from latter in vocal patterns. Has recently been considered by some authors as conspecific with *G. gnoma*; probably related to the recently discovered *G. nubicola*; further study required. Monotypic.

Distribution. C Costa Rica to W Panama, possibly to E Panama.

Descriptive notes. c. 15 cm. Strongly patterned tiny owl. Head brown, crown densely dotted white, face barred buff, eyebrows and lores white; back of head shows pattern of black "false eyes"; nuchal collar rufous; upperparts dark brown, scapulars and wing-coverts boldly spotted buffy-white; flight-feathers and tail barred; underparts white, streaked black, sides of breast rich brown with buff barring and whitish spots. Similar to *G. gnoma*; differs in somewhat smaller size, darker upperparts contrasting with heavily spotted paler crown, and darker tail. Occurs in brown and rufous morphs; latter with sparser buffy spotting, and some birds

nearly unspotted. **Voice.** Long series of whistled double "poop-poop" notes, sometimes 3 pairs of notes only; when excited, 5 higher-pitched "poop" notes in very rapid succession.

Habitat. Upland forest, mainly of pine-oak; prefers canopy and edge of forest; also in semi-open areas adjacent to forest, including pastures with scattered trees. Middle to high elevations, from timber-line down to c. 900 m on Caribbean slope, and to 1200 m on Pacific slope.

Food and Feeding. Mainly insects and small vertebrates, including birds and lizards. Perch-and-pounce predator, flying swiftly to perch in dense foliage, watching actively, and attacking in short, swift dash; if attempt fails, will usually return to perch rather than pursue.

Breeding. Lays Mar in Costa Rica; in cavity in tree, perhaps most often old woodpecker hole; 1 nest 2 m above ground in dead stub of pasture tree; 3 eggs recorded.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Costa Rica and Panama highlands EBA. Considered rare to locally (e.g. Cerro de la Muerte) fairly common in Costa Rica; rare in Panama.

Bibliography. Anon. (1998a), Heidrich *et al.* (1995a), Kelso (1937), Marín & Schmitt (1991), Ridgely & Gwynne (1989), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

127. Cloudforest Pygmy-owl

Glaucidium nubicola

French: Chevêchette des nuages

German: Nebelzwergkauz

Spanish: Mochuelo Ecuatoriano

Other common names: Ecuadorian Pygmy-owl

Taxonomy. *Glaucidium nubicola* Robbins and Stiles, 1999, south side of Quebrada San José de the Río Blanco, Carchi Province, Ecuador.

Recently discovered species; probably long overlooked as a result of morphological similarity and geographical proximity to *G. jardinii*, but vocally very distinct and also exhibits subtle but constant morphological differences. Probably most closely related to *G. gnoma* and *G. costaricanum*. Monotypic.

Distribution. W slope of Andes in Colombia (Cordillera Central) and Ecuador.

Descriptive notes. c. 16 cm; c. 76-80 g. Similar to *G. gnoma* and *G. costaricanum*. Differs in shorter tail, less extensive spotting on mantle and back, unspotted breast sides; has concealed white nuchal collar; most spots on scapulars and upperwing-coverts tinged with pale rufous. Irides yellow, bill greenish-yellow, tarsi and toes yellow, claws black. **Voice.** Series of paired whistled notes, each separated by c. 0.2 seconds, with intervals between pairs 0.32-0.37 seconds.

Habitat. Wet primary cloudforest, on steep slopes, at elevations of 1400-2000 m.

Food and Feeding. Stomach contents included insects (orthopterans and hemipterans) and a small lizard; probably also takes small birds.

Breeding. Season probably Feb-Jun. No other information.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Species little known, and no data on population level. Continuing forest destruction and degradation a major threat; most of W Ecuador, including species' type locality, completely deforested; major road construction in W Colombia is providing access to once remote areas and resulting in similar degree of deforestation. Several protected areas occur within geographical and altitudinal range of species, i.e. Los Farallones and Munchique National Parks, La Planada Nature Reserve and Río Nambi Community, in Colombia, and Cotacachi-Cayapas, Los Cedros and Maquipucuna Reserves, in Ecuador.

Bibliography. Robbins & Stiles (1999).

128. Andean Pygmy-owl

Glaucidium jardinii

French: Chevêchette des Andes

German: Andenzwergkauz

Spanish: Mochuelo Andino

Other common names: Jardine's Pygmy-owl

Taxonomy. *Palaeopsis jardinii* Bonaparte, 1855, Andes of Quito, Ecuador.

Suggested as forming superspecies with *G. bolivianum*. Has been treated as conspecific with *G. brasilianum*, or by some authors as race of *G. gnoma*; differs from both in voice, coloration and ecology. Formerly considered to include *G. costaricanum* as race, but latter now shown to be very distinct. Monotypic.

Distribution. From N Colombia and W Venezuela S through Ecuador to C Peru.

Descriptive notes. 14.5-16 cm; 65 g. Tiny, with small head and ill-defined mask; normally looks round-headed. Dimorphic, either dull dark brown with white marks, or dark chestnut with buff marks; crown has numerous small white dots (normally not streaks); short eyebrows, moustaches and broad throat patch white; nape shows conspicuous black-and-white face-like pattern; back and wings with large but scattered white spots; tail black with c. 5-6 white or buff bars; underparts boldly marked, dark breast sides with some short pale spots or bars, flanks and belly with coarse dark streaks; eyes yellow. Differs from *G. nanum* in

darker face, and shorter tail with fewer bars; from *G. brasilianum* in barring or spotting on chest sides. Juvenile with crown and nape unmarked, or has thin streaking in these areas. **Voice.** In Colombia, long series of whistled double "poop-poop" calls; in Peru, long series of evenly spaced single "poop" calls, often prefaced by c. 2 introductory whistles.

Habitat. Semi-arid to humid open cloudforest and elfin forest; montane or highland forest and adjacent semi-open land; wooded ravines with transition to swampy or grassy habitats; occupies forest canopy and middle levels, as well as forest edge; sometimes pastures with scattered trees. Occurs at 900-4000 m; in Colombia 2100-2800 m.

Food and Feeding. Birds and large insects; takes more birds than other pygmy-owls, sometimes of nearly its own size. Nocturnal and diurnal; frequently mobbed by other birds.

Breeding. In Colombia, male found in breeding condition in late Dec; nest and eggs observed in Mar. Nest in tree cavity, perhaps most often woodpecker hole.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Widespread; considered fairly common. Occurs in several protected areas throughout its range, such as Las Cajas National Recreation Area and Podocarpus National Park, both in Ecuador. Needs at least patchy forest, but little information available; probably vulnerable to forest destruction.

Bibliography. Baez *et al.* (1997), Coats (1979), Ejdlsá & Krabbe (1990), Heidrich *et al.* (1995a), Hilty & Brown (1986), König (1991b), Meyer de Schauensee & Phelps (1978), Miller (1963), Olrog (1968), Stotz *et al.* (1996).

129. Yungas Pygmy-owl

Glaucidium bolivianum

French: Chevêchette des yungas

German: Bolivienzwergkauz

Spanish: Mochuelo Boliviano

Taxonomy. *Glaucidium bolivianum* König, 1991, Salta, Argentina.

Suggested as forming superspecies with *G. jardinii*. Monotypic.

Distribution. E slope of Andes in SE Peru, WC Bolivia and NW Argentina.

Descriptive notes. c. 16 cm; male c. 55 g. Similar to *G. jardinii*. Differs in more densely spotted crown, usually more barred chest sides and shorter flank streaks. Occurs in brown, grey and rufous morphs. Juvenile with unmarked crown, flank streaks more diffuse. **Voice.** 2 or 3 whistled notes followed by trill, then rather slow series of equally spaced hollow notes; often omits first part, utters just the slow series for long periods.

Habitat. Montane forest and cloudforest; partial to *Alnus* groves with dense undergrowth and areas with heavy presence of thick moss and epiphytes; also *Podocarpus* forest. Usually high in the canopy or at middle levels. From 1400 m to 3000 m, locally down to 900 m.

Food and Feeding. Insects, small birds, possibly also reptiles. Nocturnal and diurnal, perhaps more so during cloudy wether.

Breeding. Nest in old woodpecker hole; no other information.

Movements. No information. Probably resident, though might perform some altitudinal movements.

Status and Conservation. Not globally threatened. CITES II. Appears to have declined in few years since first described. Forest destruction and degradation probably main threat, though inaccessibility of parts of range should afford some protection. Occurs in several protected areas through range, e.g. Cotapata National Park, La Paz (Bolivia), and Callegua National Park, Jujuy (Argentina); in latter, considered fairly common.

Bibliography. Canevari *et al.* (1991), Chebez (1994), Ejdlsá & Mayer (1996), Heidrich *et al.* (1995a), König (1991b), Krabbe *et al.* (1996), Martínez (1998), Stotz *et al.* (1996), Straneck, Ridgely & Rodríguez (1987)

130. Colima Pygmy-owl

Glaucidium palmarum

French: Chevêchette du Colima

German: Palmenzwergkauz

Spanish: Mochuelo de Colima

Taxonomy. *Glaucidium palmarum* Nelson, 1901, Tepic, Nayarit.

Considered member of *G. minutissimum* complex, which also includes *G. sanchezi*, *G. griseiceps*, *G. parkeri* and *G. hardyi*; further study needed to determine true relationships. Recently separated from *G. minutissimum* on basis of vocalizations. Racial differentiation uncertain, perhaps only individual variation or polymorphism. Three subspecies tentatively recognized.

Subspecies and Distribution.

G. p. oberholseri R. T. Moore, 1937 - S Sonora to S Sinaloa (NW Mexico).

G. p. palmarum Nelson, 1901 - Nayarit to Oaxaca (C Mexico).

G. p. grisei R. T. Moore, 1947 - SW Morelos and NE Guerrero (C Mexico).

Descriptive notes. 13-15 cm; male c. 45 g, female c. 50 g. Tiny; facial disc brownish, flecked white, with short whitish eyebrows; crown and nape greyish tawny-brown with extensive whitish to pale buff spotting, and slightly greyer than tawny olive-brown back; bars on wings formed by pale cinnamon to buffy-white spots; tail with 6-7 white bars. Juvenile has unspotted grey crown and nape contrasting with brown upperparts; forehead sometimes flecked whitish to buff, tail-bars pale buffy-cinnamon. **VOICE.** Song comprises 2-24 short hoots separated by long pauses; often successively increasing number of notes,

"hoo-hoo, hoo-hoo-hoo, hoo-hoo-hoo-hoo..."

Habitat. Tropical semi-deciduous forest (tropical forest), usually in foothills; locally pine-oak forest and coffee plantations from sea-level to 1500 m.

Food and Feeding. Birds, reptiles and large insects.

Breeding. Lays during May. Nest in tree cavity, often woodpecker hole; 2-4 eggs.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Fairly common to common within range, but little quantitative information available; data regarding status, population size and ecology required. Localities where species has recently been recorded include San Blas and Cerro de San Juan (Nayarit), Barranca El Choncho (Jalisco), Cañón de Lobos (Morelos), and La Soledad and Puerto Escondido (Oaxaca).

Bibliography. Anon. (1998a), Binford (1989), Buchanan (1964), Heidrich *et al.* (1995a), Howell & Webb (1995a), Schaldach (1963), Stotz *et al.* (1996), Voous (1988).

131. Tamaulipas Pygmy-owl*Glaucidium sanchezi*

French: Chevêchette du Tamaulipas

Spanish: Mochuelo Tamaulipeco

German: Sanchezzwergkauz

Taxonomy. *Glaucidium sanchezi* Lowery and Newman, 1949, San Luis Potosí, Mexico.

Considered member of *G. minutissimum* complex, which also includes *G. palmarum*, *G. griseiceps*, *G. parkeri* and *G. hardyi*; further study needed to determine true relationships. Recently separated from *G. minutissimum* on basis of vocalizations. Monotypic.

Distribution. NE Mexico (S Tamaulipas, SE San Luis Potosí and extreme N Hidalgo).

Descriptive notes. 13-18 cm; male c. 53 g. Sexual dimorphism unique in genus. Male has grey-brown crown and nape, with fine pale buff to whitish spots on forehead; nape with dark "false eyes", ground colour contrasts slightly with greyish olive-brown back; bars on wings formed by pale cinnamon to pale buff spots; tail has 6 whitish bars. Female has crown, nape and upperparts washed cinnamon, dorsally fairly uniform and distinctly redder than male; tail-bars buff to pale cinnamon. Juvenile with unspotted grey crown and nape contrasting with brown upperparts; forehead can be flecked whitish to buff; "false eye-spots" sootier, tail-bars

pale cinnamon. **VOICE.** Song comprises 1-3 long, slow-paced, high-pitched hoots with long pauses between; differs from others of genus in fewer, longer notes with long inter-note intervals.

Habitat. Subtropical, humid evergreen and semi-deciduous forest, pine-evergreen forest, typically cloudforest. Occurs at 900-2100 m.

Food and Feeding. Large insects and reptiles.

Breeding. Little information. Nest in tree cavity or hole, especially old woodpecker hole; 2-4 eggs.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Southern Sierra Madre Oriental EBA. Uncommon to fairly common. Regularly recorded around the towns of Gómez Farías (Tamaulipas) and El Naranjo (San Luis Potosí). Little information available; data on status, population size and ecology required.

Bibliography. Anon. (1998a), Heidrich *et al.* (1995a), Howell & Robbins (1995), Howell & Webb (1995a), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Voous (1988).

132. Central American Pygmy-owl*Glaucidium griseiceps*

French: Chevêchette à tête grise

Spanish: Mochuelo Centroamericano

German: Graukopf-Zwergkauz

Taxonomy. *Glaucidium griseiceps* Sharpe, 1875, tropical lowlands of Alta Vera Paz, Guatemala. Considered member of *G. minutissimum* complex, which also includes *G. palmarum*, *G. sanchezi*, *G. parkeri* and *G. hardyi*; further study needed to determine true relationships. Recently separated from *G. minutissimum* on basis of vocalizations. Racial differentiation uncertain, more study required. Three subspecies tentatively recognized.

Subspecies and Distribution.

G. g. occultum R. T. Moore, 1947 - S Mexico (SE Veracruz, N Oaxaca and Chiapas).

G. g. griseiceps Sharpe, 1875 - Guatemala, Belize and Honduras.

G. g. rarum Griscom, 1931 - Costa Rica and Panama.

Descriptive notes. 13-18 cm; male c. 51 g, female c. 10% larger. Crown and nape brown-grey to grey-brown, forehead with fine pale buff to whitish spots (can extend back to nape), nape with dark "false eyes"; tail brown, with 2-4 broken whitish to pale buff bars on upperside and 2 pale bars visible on undertail; underparts whitish with rufous-brown streaking. Juvenile with unspotted grey crown and nape contrasting with brown upperparts; "false eye-spots" sootier, tail-bars pale cinna-

mon. **VOICE.** Song begins with 2-4 equally spaced hoots, followed by very brief pause, then series of 6-18 very similar notes, "hoo-hoo, hoo-hoo-hoo..."; trills may precede hooting series.

Habitat. Humid forest and adjacent tall secondary growth, semi-open areas, old cacao plantations. In lowlands and foothills: from sea-level to 800 m in Costa Rica, to 1200 m in Mexico and to 1300 m in Guatemala.

Food and Feeding. Large insects, reptiles such as lizards, small birds such as tanagers and honeycreepers (Thraupidae), and small mammals. Often hunts by day.

Breeding. Lays Apr-May. Nest in tree cavity or old woodpecker hole; 2-4 eggs.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. In Mexico generally uncommon but locally fairly common, e.g. near Valle Nacional (Oaxaca), and around the Mayan ruins of Palenque and Bonampak (Chiapas). Fairly common in Caribbean lowlands of Costa Rica, e.g. at Finca La Selva; scarcer and locally uncommon in Panama. Generally little known; data regarding status, population size and ecology desired.

Bibliography. Anon. (1998a), Binford (1989), Heidrich *et al.* (1995a), Hilty & Brown (1986), Howell & Webb (1995a), Janzen & Pond (1976), Land (1970), Monroe (1968), Olrog (1968), Ridgely & Gwynne (1989), Stotz (1960, 1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Voous (1988), Wetmore (1968a).

133. Subtropical Pygmy-owl*Glaucidium parkeri*

French: Chevêchette de Parker

German: Parkerzwergkauz

Spanish: Mochuelo de Parker

Taxonomy. *Glaucidium parkeri* Robbins and Howell, 1995, Cerros del Sira (1550 m), Departamento Huánuco, Peru.

Considered member of *G. minutissimum* complex, which also includes *G. palmarum*, *G. sanchezi*, *G. griseiceps* and *G. hardyi*; further study needed to determine true relationships. Recently described species with highly distinctive song, possibly not closely related to others of that complex. Monotypic.

Distribution. E slope of Andes in Ecuador and Peru; possibly N to SW Colombia, possibly also extending farther S into N Bolivia.

Descriptive notes. 14 cm; c. 62 g. Tiny; crown and sides of face grey-brown, conspicuously spotted white; nape with prominent "false eyes" and concealed white nuchal collar; upperparts from mantle to rump dark brown; scapulars and upperwing-coverts dark brown, boldly spotted white, with dull olive-rufous wash to outer edges of wing-coverts and secondaries; primaries and secondaries dark brown with conspicuous, irregularly shaped white spots; tail blackish with 5 incomplete white bands; underparts from chin to undertail-coverts white, throat feathers tipped dark brown, and sides of chest medium brown;

broad, ill-defined, dull brownish olive-rufous streaks on lower chest, flanks and belly; bill greenish-yellow; eyes and toes yellow. Differs from other species of *G. minutissimum* complex in relatively large and distinct white spotting on crown, scapulars and upperwing-coverts, white (not buffish) wing-spots, less rufous ventral streaking. Juvenile undescribed. **VOICE.** Song consists of 2-4 relatively short, low-pitched hoots, with increasing length of inter-note pauses, especially between final 2 notes, "hu-hu, hu...hu", giving effect of hesitation before last note of each song; unique among New World *Glaucidium*.

Habitat. Subtropical evergreen forest at 1450-1975 m on Andean slopes; all known localities where species observed are on outlying ridges, so possibly restricted to such ridges; inhabits subcanopy.

Food and Feeding. Little known; probably large insects, small lizards and small birds.

Breeding. No information.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. Considered uncommon; easily overlooked. Predicted that species' range will be found to be more extensive than currently known.

Bibliography. Anon. (1995h), Heidrich *et al.* (1995a), Howell & Robbins (1995), Robbins & Howell (1995), Stotz *et al.* (1996), Williams *et al.* (1996).

134. Amazonian Pygmy-owl*Glaucidium hardyi*

French: Chevêchette d'Amazonie

German: Amazonaszwergkauz

Spanish: Mochuelo Amazónico

Other common names: Hardy's Pygmy-owl

Taxonomy. *Glaucidium hardyi* Vielliard, 1989, 20 km south-west of Presidente Medici, Rondônia, Brazil.

Considered member of *G. minutissimum* complex, which also includes *G. palmarum*, *G. sanchezi*, *G. griseiceps* and *G. parkeri*; traditionally considered race of *G. minutissimum*, but appears to differ in morphology, ecology and vocalizations; alternatively, considered more closely related to *G. jardini* and *G. bolivianum*; further study needed to determine true relationships. Monotypic.

Distribution. From SE Venezuela (Bolívar) E through the Guianas to N Brazil (Pará), and S to SE Peru, N & E Bolivia and S Mato Grosso.

Descriptive notes. c. 14 cm; c. 55-65 g. Tiny, with relatively small head and eyes and long wings, unmarked mantle and relatively dark, greyish rufous-brown plumage; dimorphic. Crown and nape brownish-grey with extensive white spotting, contrasting slightly with dark grey-brown back; nape with 2 black "false eye-spots", bordered by white; pale cinnamon spots on closed wings; 5 whitish bars on tail; sides of chest and streaking on underparts dusky cinnamon-brown; undertail with buffish bands. Rusty morph lacks light tail-bands. Differs from *G. parkeri* in much redder coloration and absence of bold white spots on wings; from *G. griseiceps* and *G. minutissimum* in paler and greyer head. Juvenile undescribed. **VOICE.** Rapid series of 12-36 notes running into quavering

roll or trill, at tempo of 10-13 notes per second but apparently varying across range; trill relatively loud and ringing, not analogous to the soft trills given by other members of *G. minutissimum* complex (which tend to give trill when agitated); female voice higher-pitched; frequently sings during day.

Habitat. Upper storey of humid evergreen rainforest, especially tall *terra firme*, transitional and *várzea* forest; forest edges and Amazonian lowlands; from sea-level to 850 m.

Food and Feeding. Mainly insects, probably also some small arboreal vertebrates, but little information.

Breeding. No information available.

Movements. No information. Probably resident.

Status and Conservation. Not globally threatened, CITES II. Generally considered uncommon, but may well be overlooked as it lives high up in forest; often kept as pet by native tribes. Vulnerable to forest destruction throughout range.

Bibliography. Bahr (1995), Heidrich *et al.* (1995a), Howell & Robbins (1995), Kirwan (1996a), König (1991b), O'Neill (1969), Olrog (1968), Parker & Remsen (1987), Pearson (1975), Robinson & Terborgh (1997), Sick (1993, 1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Viellard (1989).

135. Least Pygmy-owl

Glaucidium minutissimum

French: Chevêchette cabouré **German:** Kleinstzwerghauk **Spanish:** Mochuelo Mínimo
Other common names: Amazonian(!)/Brazilian Pygmy-owl

Taxonomy. *Strix minutissima* Wied, 1830, interior of the State of Bahia, Brazil.

Forms species complex with *G. palmarum*, *G. sanchezi*, *G. griseiceps*, *G. parkeri* and *G. hardyi*. All (except recently described *G. parkeri*) formerly treated as races of present species, but appear to have constant vocal differences; further research needed. Monotypic.

Distribution. E Paraguay, S & E Brazil and possibly NE Argentina (Misiones).

Descriptive notes. c. 14-15 cm. Very small; crown and nape dusky cinnamon-brown with whitish spots extending back to nape; prominent white-bordered black "eye-spots" on back of head; back rufous-brown; pale barring on wings; 5 pale bars on tail; rufous-brown to dark cinnamon-brown on chest sides, with streaks of same colour on flanks and belly; bill and cere greenish-yellow; iris and feet bright yellow. Distinguished from *G. gnoma* superspecies by smaller size and unmarked back; from *G. hardyi* by redder crown, upperparts and chest sides; from *G. parkeri* by paler, much redder plumage lacking bold white spots on scapulars

and wings; from *G. griseiceps* by more rufescent back and crown. Juvenile crown less heavily spotted, nape lacks "eye-spots". Southernmost populations palest and most rufous. **VOICE.** Song consists of series of double, low-pitched, long hoots, each separated by pause about equal to duration of note, and given in bouts that may last for long periods; also soft, quavering trill, sometimes repeated several times, usually prefacing hooting bouts; when excited, may utter up to 4 whistles; calls just before dawn, less often after dusk, only rarely during day.

Habitat. Tropical, humid evergreen forest canopy and edge to open bush canopy, from sea-level to 1100 m (mainly 500-800 m in SE Brazil).

Food and Feeding. Large insects, small lizards and small birds. Relatively short tail, similar to that of insectivorous *Micrathene whitneyi*, and fluttery, extremely manoeuvrable flight suggest less *Accipiter*-like hunting technique than *G. brasilianum* or *G. gnoma*, perhaps indicating larger proportion of insect prey in diet. Few data available indicate that species is both diurnal and nocturnal. Like other *Glaucidium*, hunts by perch-and-pounce technique.

Breeding. Little information. Presumed to breed in dry to early rainy season; nest in cavity in tree, probably most frequently woodpecker hole.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Possibly rare, though sometimes adopted as pet by native people; perhaps escapes attention because of less accessible, more forested habitat. Occurs at Estancia Itabo Private National Park, Paraguay. Habitat destruction probably represents a serious threat.

Bibliography. Allen (1995), Brooks *et al.* (1993), Dubs (1992), Forrester (1993), Hayes (1995), Heidrich *et al.* (1995a), Howell & Robbins (1995), Lowen *et al.* (1995), Olrog (1968), do Rosário (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Willis (1992).

136. Ferruginous Pygmy-owl

Glaucidium brasilianum

French: Chevêchette brune **German:** Brasilzwerghauk **Spanish:** Mochuelo Caburé

Taxonomy. *Strix brasiliana* J. F. Gmelin, 1788, Ceará, Brazil.

Considered by some authors to form superspecies with *G. tucumanum*, *G. peruanum* and *G. nanum*. Has been considered to include those as races, but recent studies have shown all to be vocally distinct and to differ in DNA. In past treated as conspecific with *G. jardinii*, but again differs in vocalizations and DNA. N populations (*cactorum*, *ridgwayi*, *saturatum*) recently proposed as forming separate species (*G. ridgwayi*); further study needed. Race *pallens* perhaps better placed in *G. tucumanum*. Twelve subspecies recognized.

Subspecies and Distribution.

G. b. cactorum van Rossem, 1937 - S Arizona S to SW Mexico.

G. b. saturatum Brodtkorb, 1941 - S Mexico (Chiapas) and Guatemala.

G. b. ridgwayi Sharpe, 1875 - S Texas through E & S Mexico to Panama.

G. b. medianum Todd, 1916 - N Colombia.

G. b. margaritae Phelps & Phelps, Jr., 1938 - Margarita I (Venezuela).

G. b. phalaenoides (Daudin, 1800) - N & E Venezuela, Trinidad and the Guianas.

G. b. duidae Chapman, 1929 - S Venezuela (Mt Duida).

G. b. olivaceum Chapman, 1939 - SE Venezuela (Mt Auyan-Tepui).

G. b. ucayalae Chapman, 1929 - Amazonian Colombia, Venezuela and Brazil. S to S Peru and N Bolivia.

G. b. brasilianum (J. F. Gmelin, 1788) - NE Brazil S to NE Argentina and N Uruguay.

G. b. pallens Brodtkorb, 1938 - E Bolivia, W Paraguay and N Argentina.

G. b. stranecki König & Wink, 1995 - C Argentina to S Uruguay.

Descriptive notes. 15-19 cm; wingspan c. 38 cm; male 46-78 g, female 64-90 g. Long, narrow tail and distinctive whistled "popping" call. Very small; facial disc brown and rufous, flecked whitish; white eyebrows often fairly bold; crown, nape and upperparts grey-brown to rufous, crown and nape spotted buffish-white, nape with white-bordered black "false eyes"; tail with 5-8 light bars; eyes lemon-yellow, and bill, cere and toes greenish-yellow to greyish-yellow; legs feathered to talons. Polymorphic, with enormous variation in streaking: grey-brown morph has brown upperparts with cinnamon or cinnamon-buff spotting, upperpart-

coverts suffused cinnamon-rufous, and 7-8 rufous tail bands; grey morph differs in having greyish-brown upperparts and white tail bands; rufous morph (less common) entirely rufous, with no bars on tail. Rufous morph differs from that of *G. gnoma* in absence of tail bands and in less cinnamon-rufous upperparts; distinguished from *G. nanum* by smaller size, less bold white spotting on wing-coverts and scapulars, and shorter tail with fewer and broader bars. Juvenile similar to adult, but probably generally darker; crown and nape often greyer, with few or no pale spots on crown, "false eye-spots" indistinct or lacking, streaking below paler and more blurred. Races differ in size, in colour tone and in strength of markings: *stranecki* significantly larger; *ridgwayi* greyish, well spotted, streaks below shorter. **VOICE.** Advertising call a prolonged series of 10-60 whistling notes, c. 3 per second, sounding like "whoop" or "poip", usually with slight jerk of tail as each note uttered; female slightly higher, becoming a twitter; also chirping and ticking notes in alarm and other contexts; calls in daytime as well as at night, often attracting mobbing from small birds.

Habitat. Tropical lowlands and foothills in primary and secondary forest, coastal and thorn scrub, bushes and scrubby second growth, open and scattered woodland, riparian woodland, deciduous and gallery forest and forest edges, coffee plantations and suburban areas; also mesquite (*Prosopis*) woodland and xero-riparian habitats. Northernmost race *cactorum* occurs in saguaro (*Carnegiea*) desert habitats, in shady riparian timberland of mesquite groves, in cottonwood-mesquite habitats, in saguaro desert forest and dry riparian scrub along desert washes, in remnant woodland of mesquite, ebony (*Pithecellobium*) and cane along rivers. In Mexico, abundant in desert-like thorn scrub and thorn-forest zones, but absent from tropical deciduous forest and higher vegetational zones; from sea-level to 300 m in E, 1200 m in W. In Guatemala, ranges from scrubby woodland to edge of evergreen forest; in Belize and Honduras, occupies transitional areas between open pine savanna and rainforest, second-growth forest, and arid to semi-humid lowland habitat; in Panama, mainly tropical zone; to 1900 m in Central America and 2250 m in Venezuela. In S of range, *stranecki* found in open country with small groves or groups of trees and bushes, sometimes in parks and larger gardens; *pallens* in dry Chaco woodland.

Food and Feeding. Mostly insects; also reptiles, birds, mammals and amphibians; examples of prey items include grasshoppers (Acrididae), Tettigoniidae, scorpions, lizards (*Sceloporus*, *Phrynosoma*), mice (*Mus*, *Baiomys*, *Dipodomys*) and flycatchers (*Myiarchus*); in S Texas study, insects comprised 58% of diet, reptiles 22.5%, birds 10.5% and mammals 8.6%; mammals and amphibians made up less than 1% of prey deliveries; also observed taking prey larger than itself, such as hispid cotton rats (*Sigmodon*) and Eastern Meadowlarks (*Sturnella magna*); also recorded attacking captive guans (*Penelope*), eventually wearing out and killing them. Diurnal and crepuscular. Peak periods of prey deliveries to nest in early morning, midday and evening perhaps reflect prey behaviour and nutritional need: in early morning, passerines preoccupied with courtship and feeding, diurnal reptiles and insects emerge, small mammals become conspicuous, making them more susceptible to predation; at midday, reptiles and insects forage more to meet increased metabolic requirements, increasing availability; during evening, small mammals emerge in dim light, visual acuity of prey diminishes, and species must sustain brood through night. May also forage excessively in early morning and cache to meet mid-afternoon nutritional needs. Hunts mostly from perch; also by dashing into thick foliage to surprise prey.

Breeding. Lays generally c. Mar-Jun, during dry to early wet season; eggs found in S Mexico (Oaxaca) in Apr-May; breeding late Jan and Apr in Yucatán Peninsula; juveniles in Mar and July in NE Venezuela; probably lays in Oct in S of range. Probably monogamous, pair-bond lasting 1 year. Nest in natural cavity of tree, stump or snag, in woodpecker hole, tree fork or depression, trees used include mesquite, pine, cypress (*Cupressus*), palmetto (*Sabal*); no known records of nesting in saguaro; occasionally in hole in sand bank or termite mound; also known to use nestboxes, and in Argentina and Brazil old mud nest of Rufous Horned (Furnarius rufus). 2-5 eggs, usually 3 (average of 43 nests, 3-3); incubation 22-30 days; young hatch with eyes closed; female incubates and broods, male collects food for female and young, both adults brought prey to nest-site 3 weeks after young hatched; intense brood competition over prey items, occasionally resulting in fatal injuries to young; fledging 27-30 days, young cared for by both parents for at least 3 weeks more; young in captivity observed to return to nestbox to sleep. Sexual maturity at 1 year.

Movements. Resident, at least in N of range; no evidence of movements elsewhere.

Status and Conservation. Not globally threatened, CITES II. In USA, has declined drastically during 20th century; in Texas (lower Rio Grande valley), once generally distributed in riparian trees, brush, palm and mesquite thickets, now limited to remnant mesquite thickets and listed as threatened; in Arizona, has suffered from loss of preferred saguaro and associated riparian habitats and listed as endangered; future in USA uncertain. In Central and South America, considered widespread; fairly common to locally common in Panama and Colombia, and fairly common in Costa Rica; in some countries the only common pygmy-owl. Occurs in a considerable number of protected areas in most countries throughout its extensive range. In South America, this species (and other *Glaucidium*) kept as cage-birds in belief that they bring luck and success in love.

Bibliography. Anon. (1988), Baicich & Harrison (1997), Belton (1984), Binford (1989), Brooks *et al.* (1993), Canevari *et al.* (1991), Contreras *et al.* (1990), Eckert (1974), Fjeldså & Krabbe (1990), Friedmann (1948), Haverschmidt & Mees (1994), Heidrich *et al.* (1995a), Heintzelman (1992), Herklotz (1961), Hilty & Brown (1986), Howell & Webb (1995a), Johnson (1988), Johnson (1967), Kaufman (1996), König (1991b), König & Wink (1995), Land (1970), Lowery & Dalquest (1951), Marin *et al.* (1989), Meyer de Schauensee & Phelps (1978), Millsap & Johnson (1988), Monroe (1968), Olrog (1985), de la Peña (1994), Proudfoot & Beasom (1996, 1997), Proudfoot & Radomski (1997), Ridgely & Gwynne (1989), do Rosário (1996), Rowley (1984), Saibene *et al.* (1996), Schaldach (1963), Short (1975), Sick (1993, 1997), Slud (1964), Snyder (1966), Siles & Skutch (1989), Stotz *et al.* (1996), Tyler & Phillips (1978), Voous (1988), Wauer *et al.* (1993), Wetmore (1926, 1939, 1968a), Wolfe & de la Torre (1990), Zimmer (1930).

137. Tucuman Pygmy-owl

Glaucidium tucumanum

French: Chevêchette de Tucuman German: Tucumanzwergkauz Spanish: Mochuelo Tucumano

Taxonomy. *Glaucidium brasilianum tucumanum* Chapman, 1922, Rosario de Lerma, 4800 feet [c. 1600 m], Salta, Argentina.Considered by some authors to form superspecies with *G. brasilianum*, *G. peruanum* and *G. nanum*. Formerly treated as race of *G. brasilianum*, but differs in vocalizations and DNA. Race *pallens* of latter, with adjacent distribution and occupying similar habitat, perhaps better included with present species. Monotypic.**Distribution.** NW Argentina from Salta and Tucumán to at least Córdoba.**Descriptive notes.** 16-17.5 cm; c. 55 g. Dimorphic. Grey morph dark grey-brown to slaty-brown above, crown with very small, fine pale streaks, head sides and nape spotted, nape also with indication of "false eyes", back generally completely dark; wing-coverts and scapulars spotted light buffish-white; tail blackish-brown with 5-6 thin white bars; underparts whitish, darker on chest sides, streaked dark on flanks; iris and feet yellow; bill greyish-yellow. Rufous morph with fewer streaks and spots on head. Distinguished from *G. brasilianum* by darker upperside. Tends to become smaller and paler towards N of range.**VOICE.** Series of 10-30 or more equally spaced upward-inflected notes, c. 2 per second, becoming louder towards end; also single "wik" and chirping notes.**Habitat.** Semi-open, dry thorn forest: Chaco thorn-scrub and dry Chaco woodland. Generally up to c. 1500 m, locally to 1800 m.**Food and Feeding.** Little information; takes small birds, also other small vertebrates, and insects. **Breeding.** Males in breeding condition (enlarged testes) taken in Oct and Nov. Nest in old woodpecker hole in tree or cactus. 3-5 eggs; incubation by female, fed by male.**Movements.** Presumed resident.**Status and Conservation.** Not globally threatened. CITES II. Status uncertain, but probably not uncommon locally. Habitat destruction the main threat.**Bibliography.** Canevari *et al.* (1991), Chapman (1922), Friedmann (1927), Heidrich *et al.* (1995a), Stotz *et al.* (1996).

138. Peruvian Pygmy-owl

Glaucidium peruanum

French: Chevêchette du Pérou German: Peruzwergkauz Spanish: Mochuelo Peruano

Taxonomy. *Glaucidium peruanum* König, 1991, Ninabamba (2100 m), Apurímac, Peru. Considered to form superspecies with *G. brasilianum*, *G. tucumanum* and *G. nanum*. Recently separated from *G. brasilianum* based on bioacoustical analysis and DNA evidence. Even more recent research suggests that populations currently included in present species actually constitute two species, one on Pacific slope and the other on Amazonian slope; they differ markedly in morphology and, particularly, vocalizations; name *peruanum* is applicable to birds of Amazonian slope; scientific description of form from Pacific slope currently in preparation (see page 84). Probably constitutes two species, both apparently monotypic.**Distribution.** W Ecuador (Manabí) S through W Peru to N Chile; also E of Andes in extreme SE Ecuador (Zamora-Chinchi) and Marañón drainage of Peru.**Descriptive notes.** c. 15-17 cm; c. 60 g. Amazonian slope birds have quite large, rounded pale vinaceous-buff spots on crown, and conspicuous "face pattern" on nape, with large black patches, bordered below by almost continuous buff band. Very similar to *G. tucumanum*; best distinguished by voice. Sexually dimorphic in size, with male tiny. Juvenile has unspotted crown. Pacific slope birds have abundant pale streaks on crown, and poorly marked "face pattern" on nape; more fulvous in coloration, some markedly rufous. **VOICE.** On Amazonian slope birds song has a sharply declining pitch and speed. On Pacific slope, song is long

sequence of equally spaced notes in rapid succession (6-7 notes per second) on a constant pitch.

Habitat. Riparian woodland, thickets, semi-arid woodland, mesquite, and elfin forest; also agricultural country with trees, and locally urban parks. From lowlands and foothills to c. 3000 m.**Food and Feeding.** Insects and small birds known to be taken. Forages in middle storey and canopy; hunts from perch.**Breeding.** Nest situated in tree hole, often of woodpecker; no other information.**Movements.** Probably resident.**Status and Conservation.** Not globally threatened. CITES II. Generally considered rare, but probably relatively common locally; difficult to observe. Only recently described, and conservation status may require reassessment, but as two species are probably involved, taxonomic clarification is immediate priority; research required on both forms.**Bibliography.** Becker & López (1997), Best *et al.* (1996), Heidrich *et al.* (1995a), König (1991b), Parker *et al.* (1995), Pople *et al.* (1997), Stotz *et al.* (1996), Taylor (1995), Williams *et al.* (1996).

139. Austral Pygmy-owl

Glaucidium nanum

French: Chevêchette australe German: Araukanerkauz Spanish: Mochuelo Patagón

Taxonomy. *Strix nana* King, 1828, Port Famine, Straits of Magellan.Considered by some authors to form superspecies with *G. brasilianum*, *G. tucumanum* and *G. peruanum*. Sometimes treated as race of *G. brasilianum*, but apparently some subtle differences in vocalizations exist; recently shown to differ also in DNA. Monotypic.**Distribution.** Breeds S Chile and S Argentina S to Tierra del Fuego, some wintering farther N in Chile and Argentina.**Descriptive notes.** 17-22 cm; male 55-75 g, female 70-100 g. Dimorphic. Grey-brown morph grey-brown overall, with white spotting; crown minutely streaked white, and black "false eye-spots" on back of head; numerous white spots on wing-coverts and scapulars; tail with 7-10 distinct rufous or rarely white bars; densely streaked below. Rufous morph similar, but with rufous replacing grey-brown. Differs from *G. brasilianum* in larger size and darker general coloration; rufous morph less fox-red than in latter species; differs from *G. jardiinii* in having more numerous and rufous tail-bars, and streaked (not dotted) crown. Juvenile has uniform brown crown.**nape, mantle and chest. VOICE.** Series of 22-66 short whistles repeated in rapid succession, at about 3 whistles per second, each with upward inflection; also chirping and ticking notes.**Habitat.** Warm desert areas, oases and puna, warm shrubland, temperate forest, and cold forest of southern beech (*Nothofagus*) interspersed with steppe areas; also open woodland, thorn scrub, and sometimes city parks and gardens. Found in evergreen shrubland in C Chile and in humid forest in S Chile; in southernmost Chile, southern beech forest and Patagonian scrub. Occurs from sea-level to 2000 m in Chile, and to 1500 m in Patagonia (Argentina).**Food and Feeding.** Primarily birds, such as Plain-mantled Tit-spinetail (*Leptasthenura aegithaloides*), White-crested Elaenia (*Elaenia albiceps*), Common Dicaea-finch (*Dicaea dicaea*), Austral Blackbird (*Curaeus curaeus*), Moustached Turca (*Pteroptochos megapodius*), juvenile Chilean Tinamou (*Nothoprocta perdicaria*), Rock Dove (*Columba livia*) and domestic fowl; often takes prey considerably larger than itself, even twice its size; average prey weight 45% of owl's size. Other prey includes insects, reptiles, arachnids, small mammals and many nocturnal tenebrionid beetles; in NC Chile found to be better depicted as small-mammal eater that secondarily preys on birds, this probably reflecting mouse outbreak that occurred during study and suggesting that species is opportunistic. Most often described as nocturnal and diurnal, but in Patagonia observed as mostly crepuscular and diurnal. A perch-and-wait predator; will attack passerines in mist-nets; remains found under plucking sites indicate that only wing and tail feathers removed; caches surplus prey in rock crevices.**Breeding.** Lays in Sept-Nov (austral spring). Nest in hollowed tree trunk, tree crotch, rock bank, ground cavity, rodent burrow or building; also uses cavities of Dark-bellied Cinclodes (*Cinclodes patagonicus*), Chilean Flicker (*Colaptes pitius*) and Striped Woodpecker (*Picoides lignarius*); nest may be reused several times, but unclear whether by same pair; pairs generally nest c. 200 m or more apart, report of 2 pairs sharing same tree considered highly unlikely. Single clutch of 3-5 eggs; incubation period 26-28 days, report of 15-17 days (shortest incubation reported for any owl) requires corroboration.**Movements.** Partial migrant. Southernmost populations migrate N in late autumn to N Argentina (Buenos Aires, Santa Fe, Entre Ríos and Tucumán) and N Chile; population in Chile's southernmost Magallanes region resident.**Status and Conservation.** Not globally threatened. CITES II. In Chile, considered most abundant owl; common in C & S in summer, autumn and winter, and either leaves or becomes secretive in spring; appears to be increasing in C Chile, despite being killed by rural people because believed to be bird of ill omen. In Argentina, abundant in region S from Neuquén and Río Negro. Seems generally tolerant of human-induced habitat changes, and gardening may increase avian prey (passerine) abundance. Occurs in a number of protected areas, e.g. Tierra del Fuego National Park, where it can be fairly common and very tame.**Bibliography.** Canevari *et al.* (1991), Chebez & Bosso (1992), Ejelds & Krabbe (1990), Heidrich *et al.* (1995a), Hellmayr (1932), Humphrey *et al.* (1970), Jaksic *et al.* (1992), Jiménez & Jaksic (1989, 1993), Johnson (1967), König (1987, 1991b), Marin *et al.* (1989), Meyer de Schauensee (1966, 1982), Narosky & di Giacomo (1993), Nellar (1993), Norez *et al.* (1983), Olrog (1984), de la Peña, M.R. (1994, 1997), Stotz *et al.* (1996), Wetmore (1926).

140. Cuban Pygmy-owl

Glaucidium siju

French: Chevêchette de Cuba German: Kubakauz Spanish: Mochuelo Sijú

Taxonomy. *Noctua siju* d'Orbigny, 1839, Cuba.

Affinities uncertain. Two subspecies recognized.

Subspecies and Distribution.*G. s. siju* (d'Orbigny, 1839) - Cuba.*G. s. vittatum* Ridgway, 1914 - I of Pines.**Descriptive notes.** 16-17 cm; 55-90 g. Tiny; crown, head sides and back greyish-brown with white spots; eyebrows whitish to cinnamon; nape with white-edged dark "eye-spots", mantle barred; tail with 5-6 white bars; throat brown; breast sides and flanks brownish, barred darker, breast centre plain white, rest of underparts off-white with dark brown spots and streaks; bill, iris and tarsus yellow. Rufous morph also occurs. Juvenile with unspotted crown. Race *vittatum* larger, upperparts more clearly barred.**VOICE.** Whistle-like "jiu" at short intervals, or repeated "jiu, jiu, jiu, jiu", starting softly and increasing in frequency and tone.**Habitat.** Coastal, deciduous and montane forest, forest edges, second growth, and open areas with scattered trees and cultivated fields; locally, plantations and larger parks. From sea-level to 1500 m.**Food and Feeding.** Insects; also lizards, frogs, small mammals and birds. Hunts from perch.**Breeding.** Breeds in dry season. Lays in abandoned nest of other bird or in natural tree cavity; 3-4 eggs; incubation by female.**Movements.** Resident.**Status and Conservation.** Not globally threatened. CITES II. Considered fairly common to common, although little information on species' biology, and no conclusive comments can be made regarding status. Also, race *vittatum* has restricted distribution. Adversely affected by destruction of small patches of woodland; conservation problems the same as those that face island species generally.**Bibliography.** Allen (1961), Anon. (1998a), Barbour (1943), Bond (1985), Criado *et al.* (1995), Gundlach (1873), Heidrich *et al.* (1995a), Raffaele *et al.* (1998), Stotz *et al.* (1996), Sulley & Sulley (1992), Wotzkow (1990).

141. Red-chested Owlet

Glaucidium tephronotum

French: Chevêchette à pieds jaunes **German:** Rotbrustkauz **Spanish:** Mochuelo Pechirrojo
Other common names: Yellow-legged Owlet

Taxonomy. *Glaucidium tephronotum* Sharpe, 1875, South America; error = Mampong, Ashanti, Ghana.

Relationships uncertain. Proposed races *lukolelae* from CW Zaire and *kivuense* from E Zaire included within race *medje*. Four subspecies currently recognized.

Subspecies and Distribution.

G. t. tephronotum Sharpe, 1875 - Liberia, Ivory Coast and Ghana.

G. t. pyrafrati Bates, 1911 - Cameroon.

G. t. medje Chapin, 1932 - Congo Basin, E Zaire and SW Uganda.

G. t. elongense Granvik, 1934 - E Uganda and W Kenya.

with pale spots on head sides, heavy spotting below, including breast sides. **Voice.** Series of 2-20 high whistles given at 2-second intervals, "teu, teu, teu, teu,..." or yelping "wook wook wook..."; sometimes double note, "wu wook, wu wook"; breaks of 2-5 seconds between series; female may give series of faster, higher whistling notes.

Habitat. Dense primary forest and forest-scrub mosaic; also recorded in logged forest. In lowlands and at up to 2150 m.

Food and Feeding. Varied; eats insects such as mantises, cockroaches, crickets, earwigs and cicadas; pursues moths and other winged insects in forest canopy; also some small mammals and birds. Mainly nocturnal, hunting in forest openings and edges. Reports of diurnal activity: recorded active on rainy afternoon, one observed flying at midday, another seen catching passerine in daylight, but usually roosts in cavities by day.

Breeding. Little known. In Liberia, a female with enlarged ovaries and having laid recently in late mar; in Ghana, a collected female finished laying in Feb. Nest in tree cavity or hollow; 2-4 eggs.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Rare and hard to locate. Nominate race rare to not uncommon in Liberia, e.g. Mt Nimba; race *elongense* uncommon in Kenya at Mt Elgon, N Nandi, Kakamega, Mau and Trans-Mara Forests; only 1 fully confirmed nesting record in Kenya. Species occurs in several protected areas, such as Impenetrable (Bwindi) Forest National Park, Uganda, and Mount Elgon National Park, Kenya. In Central African Republic, up to 4 singers heard from same station in exploited forest may suggest that species can be locally common and that it can tolerate some degree of habitat alteration.

Bibliography. Bannerman (1953), Bowden & Andrews (1994), Brown (1977), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dowsett (1989b, 1990), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (1999), Field (1998), Fry *et al.* (1988), Gatter (1988, 1997), Grimes (1987), Kemp & Kemp (1998), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1957, 1970), Short *et al.* (1990), Snow (1978), Thiollay (1985), Zimmerman, D.A. (1972), Zimmerman, D.A. *et al.* (1996).

142. Sjöstedt's Owlet

Glaucidium sjöstedti

French: Chevêchette à queue barrée **German:** Prachtkauz **Spanish:** Mochuelo del Congo
Other common names: Sjöstedt's Barred Owlet, Chestnut-backed Owlet(!)

Taxonomy. *Glaucidium sjöstedti* Reichenow, 1893, Mount Cameroon.

Affinities uncertain. Monotypic.

Distribution. Cameroon, Gabon, N Congo, S Central African Republic and NW & C Zaire.

accelerating notes that drop in pitch and volume at end, "kroo kroo krookrookrookroo"; calls mainly at dawn and dusk.

Habitat. Restricted to primary lowland forest, ascending somewhat higher on Mt Cameroon; avoids forest edge or damper places where vine-palm flourishes.

Food and Feeding. Mainly insects such as grasshoppers and dung beetles; also spiders, mice, small snakes, crabs and nestling birds; known to attack small birds caught in mist nets. Nocturnal hunter;

Descriptive notes. c. 20-25 cm; c. 140 g. Head and neck brown with white barring; facial disc brown with buff-white barring; eyes and bill yellow; distinct white throat and eyebrows; upper back barred brown and white, rest of upperparts deep chestnut; flight-feathers conspicuously barred brown and white; tail brown with thin white bars; underparts cinnamon, uniformly barred brown. Juvenile paler, with buffy underparts and chestnut wash across throat, faint dark barring on upper chest, also barred buff on scapulars. **Voice.** 2-4 notes uttered over 2 seconds, "kroo-kroo-kroo", with 1-second interval between series; sometimes male gives

sometimes mobbed by small birds if disturbed from daytime roost. Hunts in understorey, within 2 m of ground.

Breeding. Lays in Jul in Gabon; nestlings found in Cameroon in Feb, May, Aug, Nov and Dec. Nest in cavity or natural tree hollow c. 1-5 m above ground; based on spacing of calling males in Gabon, territory c. 10-12 ha, 2 nestlings collected once, so clutch size at least 2; incubation c. 28 days; fledging period unknown.

Movements. Probably resident, making only local movements.

Status and Conservation. Not globally threatened. CITES II. Uncommon in most of range; most frequent in Gabon, where locally not uncommon, e.g. at La Lopé Reserve. Some authors give status as uncertain, possibly endangered; habitat destruction almost certainly a threat. Much needs to be learned of species' breeding biology and distribution before accurate assessment of its status can be made.

Bibliography. Bannerman (1953), Bowden & Andrews (1994), Brosset & Éard (1986), Christy & Clarke (1994), Dowsett (1989a, 1989b), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (1999), Elgood *et al.* (1994), Fry *et al.* (1988), Kemp & Kemp (1998), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1970), Snow (1978).

143. Asian Barred Owlet

Glaucidium cuculoides

French: Chevêchette cuculoïde **German:** Kuckuckstrillerkauz **Spanish:** Mochuelo Cuco
Other common names: Barred Owlet, Cuckoo Owlet(!), Cuckoo Owl

Taxonomy. *Noctua cuculoides* Vigors, 1831, Simla-Almora district, Himalayas.

Possibly forms superspecies with *G. castanonotum*. Sometimes considered to include latter and *G. castanonotum* as races. Eight subspecies recognized.

Subspecies and Distribution.

G. c. cuculoides (Vigors, 1831) - Himalayas from NE Pakistan and Kashmir E to W Sikkim.

G. c. austerum Ripley, 1948 - E Sikkim, Bhutan, NE Assam and NW Myanmar.

G. c. rufescens Stuart Baker, 1926 - NE India, Bangladesh and N Myanmar.

G. c. bruegeli (Parrot, 1908) - S Myanmar and S Thailand.

G. c. delacouri Ripley, 1948 - N Indochina.

G. c. deignani Ripley, 1948 - SE Thailand and S Indochina.

G. c. whiteleyi (Blyth, 1867) - W, C & SE China and NE Vietnam.

G. c. persimile Hartert, 1910 - Hainan.

Descriptive notes. 22-25 cm; 150-175 g, female slightly larger. Head grey-brown, barred buff, with whitish eyebrows; upperparts dark brown, barred buff to fulvous; scapulars edged buff-white, forming row of spots down sides of back; tail and wings dark brown, barred; below, white patches on throat and middle breast, rest of underparts barred dark and light; iris yellow; bill yellow-green, darker on cere; feet greyish-yellow or dull horn-green. Distinguished from *Athene brama* by barred instead of spotted upperparts; from *G. radiatum* by larger size and darker coloration. Juvenile has breast streaked, not barred, and is more rufous on crown and mantle. E races more rufous, with lower underparts and flanks broadly streaked rufous on white. **Voice.** Trill, lasting 7-14 seconds; series of squawks, rising to crescendo, then ending abruptly; during breeding season, more musical, bubbling whistle, "wowowowowowowow"; territorial song varied series of barking high notes; loud, clear "hooloo hooloo hooloo", broadening to violent "kok kok", ending with short, shrill "chiurr".

Habitat. Open forest of pine and oak, subtropical evergreen jungle, scrub; sometimes near human habitation. From lowland plains to 1800 m; to 2700 m in Himalayas of N Pakistan.

Food and Feeding. Mainly insects, including beetles and grasshoppers; also lizards, rodents, small birds and frogs. Mostly diurnal. Hunts from perch, with undulating flight; catches birds such as quail (*Coturnix*, *Perdula*) in air; insects caught in flight or on ground.

Breeding. Lays Apr-Jun in Nepal, Apr-May elsewhere; pair observed together throughout Mar-Aug; fledgling found early Jul. Nest in unlined tree cavity; may kill barbets (*Capitonidae*) and woodpeckers (*Picidae*) for cavity. 4 eggs (3-5); both sexes said to incubate and to feed young, requires confirmation.

Movements. Mainly resident. Makes elevational movements on S Himalayan slopes; may also make vertical movements in W Chinese mountains, descending to lowlands of Sichuan and river bottoms of W Hubei; possibly more extensive movements in NC China, where winter climate severe.

Status and Conservation. Not globally threatened. CITES II. Common over most of range. Tolerates human proximity; nests in fruit gardens near Bangkok, Thailand, and in coconut plantations; in China, occurs close to farmhouses and footpaths in rice fields.

Bibliography. Ali & Ripley (1981), Ali *et al.* (1996), Bangs & Van Tyne (1931), Cheng Tsohsin (1987), Deignan (1945), Dudgeon (1901), Étchécopar & Hue (1978), Grimmett *et al.* (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Lekagul & Round (1991), Majumdar *et al.* (1992), Riley (1938), Ripley (1982), Roberts (1991), Smythies (1986), Stepanyan (1995), Voous (1988), Wells (1999), Zhao Zhengjie (1995).

144. Javan Owlet

Glaucidium castanonotum

French: Chevêchette spadicee **German:** Trillerkauz **Spanish:** Mochuelo de Java
Other common names: Javan Barred/Chestnut-winged/Spadiced Owlet, Cuckoo Owlet(!)

Taxonomy. *Strix castanonotera* Horsfield, 1821, Java.

Possibly forms superspecies with *G. cuculoides*. Formerly treated as isolated race of latter. Monotypic.

Distribution. Java and Bali.

Descriptive notes. c. 24 cm. Indistinct facial disc barred rufous and orange-yellow, with white eyebrows; head brown with fine pale orange-yellow barring; upperparts rufous-chestnut, scapulars

edged with broken white line; wings and tail barred orange-yellow and brown; below, rufous breast sides barred orange, flanks and belly sides broadly streaked brownish-rufous; iris yellow-brown; bill greenish with yellow tip; feet greenish-yellow. Voice, Rapid trill, descending in pitch while increasing in volume; given at dawn and dusk.

Habitat. Primary and secondary forest, from lowlands to 900 m, locally higher, to 2000 m.

Food and Feeding. Insects, mice and small birds; occasionally reptiles. Mainly nocturnal, but sometimes active by day. Hunts from perch, pounces on prey.

Breeding. Probably similar to that of *G. cuculoides*; presumed to nest in woodpecker hole or other tree cavity; 4 eggs. No other information available.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Considered common locally in forest fragments and hills. Little information available; ecology and tolerance of human activities may be similar to those of *G. cuculoides*; detailed information much desired. Habitat loss probably main threat.

Bibliography. Andrew (1992), van Balen (1991), Hellebrekers & Hoogerwerf (1967), Hoogerwerf (1949a), Inskipp *et al.* (1996), MacKinnon (1988), MacKinnon & Phillips (1993), Mees (1971), Voous (1988).

145. Jungle Owlet

Glaucidium radiatum

French: Chevêchette de jungle **German:** Dschungelkauz **Spanish:** Mochuelo de Jungla
Other common names: Barred Jungle Owlet

Taxonomy. *Strix Radiata* Tickell, 1833, jungles of Borahum and Dholbhum.

Possibly forms superspecies with *G. castanonotum*, with which has been considered conspecific; although both present in Sri Lanka, they occupy different habitats. Two subspecies recognized.

Subspecies and Distribution.

G. r. radiatum (Tickell, 1833) - Himalayas from Himachal Pradesh E to Bhutan, Bangladesh and possibly W Myanmar, and S through India; also Sri Lanka.

G. r. malabaricum (Blyth, 1846) - SW India.

Descriptive notes. 20-24 cm; 90-114 g. Small, squat, round-headed owl. Facial disc barred brown and cream, with distinct white eyebrows, chin and moustachial streak; dark brown above, wings more rufous, all barred uniformly with pale rufous; below, barred dark olive-brown and white; rufous patch on underwing conspicuous in flight; iris bright yellow; bill greenish-white; feet greenish-yellow. Differs from *G. cuculoides* in smaller size, paler general appearance and rufous primaries. Juvenile undescribed. Race *malabaricum* much darker, more rufous overall.

VOICE. Long, monotonous, musical "cur-cur-

cur-cur-ur", fading towards end; uttered for up to 15 minutes at a time; also "kao" repeated 2-3 times, followed by quickening series of fading double notes, resembles Red Junglefowl (*Gallus gallus*).

Habitat. Both dense and sparse deciduous forest, scrub, *terai* and dun in Nepal; sometimes near cultivation; also secondary growth from cleared forest; avoids wet forest. From lowlands to 915 m in Nepal; up to 2000 m in rest of range.

Food and Feeding. Mostly insects, including beetles, locusts, grasshoppers and cicadas; also lizards, rodents and small birds. Largely crepuscular; most active hour before dusk and hour after sunrise. Flight swift and direct, similar to small hawk (*Accipiter*).

Breeding. Mar-Jun in Nepal, Mar-May elsewhere. Nest in unlined tree cavity, 3-8 m above ground. Usually 3 eggs (2-4); in Sri Lanka, only 2.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Status poorly known. Common in Nepal and India; common in Sri Lanka, but suffering under deforestation. Occurs in several protected areas such as Chitwan National Park, Nepal, Corbett and Periyar National Parks, India, and Yala National Park, Sri Lanka. Attempts at captive breeding unsuccessful: copulation occurred but no eggs laid.

Bibliography. Ali (1996), Ali & Ripley (1981), Daniels (1997), Gokula & Vijayan (1997), Grimmett *et al.* (1998), Henry (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Lamsfuss (1998), Majumdar *et al.* (1992), Mohan (1997), Neelakantan (1971), Phillips (1978), Ripley (1982), Saha & Dasgupta (1992), Smythies (1986).

146. Chestnut-backed Owlet

Glaucidium castanonotum

French: Chevêchette à dos marron **German:** Kastanienmantelkauz **Spanish:** Mochuelo de Ceilán
Other common names: Sri Lanka Chestnut-backed Owlet

Taxonomy. *Athene castanonota* Blyth, 1852, Sri Lanka.

Possibly forms superspecies with *G. radiatum*; although both present in Sri Lanka, they occupy different habitats. Formerly treated as race of either *G. cuculoides* or *G. radiatum*. Monotypic.

Distribution. Sri Lanka.

Descriptive notes. 19 cm. Small owl, similar in shape and size to *G. radiatum*. Differs from latter in darker and greyer head; entire upperparts barred chestnut and blackish; and underparts white, barred dark on breast and flanks, but streaked olive-brown on belly. Juvenile undescribed. Voice, Far-carrying "krraw krraw krraw": calls during day.

Habitat. Dense forest of wet zone, from lowlands to 1950 m. Has been recorded at edge of rubber plantation. Frequents tops of tall trees, usually on steep hillsides.

Food and Feeding. Mostly insects; also mice, lizards and small birds; takes larger prey primarily when young being fed. Often hunts in daytime.

Bibliography. Ali (1996), Ali & Ripley (1981), Grimmett *et al.* (1998), Henry (1998), Hoffmann (1998), Inskipp *et al.* (1996), Kotagama & Fernando (1994), Lamsfuss (1998), Phillips (1978), Ripley (1982), Stattersfield *et al.* (1998), Wijesinghe (1994).

147. African Barred Owlet

Glaucidium capense

French: Chevêchette du Cap **German:** Kapkauz **Spanish:** Mochuelo de El Cabo
Other common names: Barred Owl(!), Ngami Owlet (*ngamiense*); Scheffler's Owlet, Eastern Barred Owlet (*scheffleri*)

Taxonomy. *Noctua Capensis* A. Smith, 1834, 17 km west of Bathurst, eastern Cape Province.

Has been suggested as forming superspecies with *G. castaneum* and *G. albertinum*. Some authors have considered present species conspecific with *G. castaneum*, or, alternatively, to include only disjunct W African race *etcheopari* of that species. Recent studies have indicated that *ngamiense* (including intergrade forms "*clanceyi*" and "*robertsi*") and *scheffleri* should both be regarded as distinct species, on basis of morphology, geographical distribution, habitat preferences and slight vocal differences, but more research needed. Three subspecies recognized.

Subspecies and Distribution.

G. c. scheffleri Neumann, 1911 - extreme S Somalia and E Kenya to NE Tanzania.

G. c. ngamiense (Roberts, 1932) - C Tanzania and SE Zaire across to S Angola, S to N Namibia, N Botswana, E Transvaal and SC Mozambique; also Mafia I.

G. c. capense (A. Smith, 1834) - from S Mozambique S to E Cape.

Descriptive notes. c. 20-22 cm; wingspan c. 45 cm; male 83-132 g, female 93-139 g; male 93-100 g, female 95-113 g (*scheffleri*). Small owl with large, round head. Head and nape grey-brown with fine white spots; facial disc white with light grey bars; upperparts brown, barred paler; scapulars and wing-coverts with broad white edges; flight-feathers brown with broad rufous bands; tail similarly banded; upper breast cinnamon, barred buff; lower breast and belly white with large brown feather tips, giving spotted appearance; eyes yellow, bill greenish-yellow. Juvenile browner on head and neck, with less barring and spotting on breast.

Race *ngamiense* smaller than nominate, head brown with white bars (not fine white spots), facial disc with broad white bars, upperparts light brown with distinct narrow buff bars, tail bands broader, belly with smaller dark spots; *scheffleri* has brown head evenly spotted white, facial disc with faint greyish barring, more prominent white eyebrows, darker brown upperparts with less barring, upper breast creamy-white with rusty-brown bars, and juvenile resembles adult. Voice, Nominative race gives 5-8 notes at 1 per second, rising in pitch and falling slightly with third note, "cow, cow, cow..."; sequence repeated 15-20 seconds later. Race *ngamiense* gives series of 6-10 low, whistled notes with half-second intervals between; may rise and fall in volume; also series of 35-55 fast purring trills; calls mainly at night. Race *scheffleri* utters 6-10 loud notes that increase and decrease in volume, "kerr-kerr-kerr-KERR-KERR-kerr", often followed by purring whistle; also repeats monotonous single note, "weu-weu-weu-weu...".

Habitat. Woodland and riparian trees in open country, usually below 1200 m; *ngamiense* inhabits lowland and montane forest and dense secondary growth; *scheffleri* coastal forest and woodland, again mainly below 1200 m.

Food and Feeding. Insects such as beetles, grasshoppers and caterpillars; small mammals and birds. Most details recorded for *ngamiense*; mainly insectivorous, also taking scorpions and occasionally small birds and amphibians such as skinks and frogs; preference for small prey may be due to weak feet (smaller than those of *G. perlatus*). Presence of leaf litter to support ground insects may limit distribution. Active during day, often hunting at dusk and early morning, but more nocturnal than *G. perlatus*; frequently mobbed by passerines; bathes regularly. Hunts by searching ground from perch, and dropping to catch prey. Like congeners, flies low and fast with dipping woodpecker-like flight, but does not flick tail back and forth when excited. Race *scheffleri* also recorded taking small reptiles and probably arthropods; perches in fairly open sites during day; mainly diurnal but also nocturnal; most active at dusk and early morning.

Breeding. Little information. Lays Sept-Nov in E & S Africa. Only few nests found, none studied in detail, and much of biology unknown: nest in cavity 3-6 m above ground; 2-3 eggs; both parents may feed young, which fledge at c. 32 days.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Nominative race very rare in E Cape, where first specimen collected in 1824, with another in 1826; speculation that locality may have been mislabelled or, if correct, owl extinct; rediscovered in 1980, when one found dead next to house in Kenton-on-Sea; in Aug 1981 one photographed during daytime at Hluleka Nature Reserve on Transkei coast. Threatened by habitat destruction, bush clearance for agriculture occurring at alarming rate; especially dangerous to survival since ecology and exact habitat affinities so poorly understood. Race *ngamiense* localized but common in parts of range; reported as common at Moremi Wildlife Reserve in Botswana, and also in riparian forest along Okavango R in Caprivi Strip, Namibia. Race *scheffleri* uncommon; scattered inland records from Kondoa, Mombasa, Itala and Kibwezi; rare in N Tanzania; few records from S Somalia, where status uncertain but possibly commoner than the handful of records imply.

Bibliography. Alexander (1997), Anon. (1985b), Ash & Miskell (1998), Benson & Benson (1977), Benson *et al.* (1971), Brooke (1984), Brooke *et al.* (1983), Carlyon (1985), Carlyon & Meakin (1985), Dowsett & Dowsett-

Lemaire (1993), Dowsett & Forbes-Watson (1993), Fanshawe & Ngala (1994), Fry *et al.* (1988), Ginn *et al.* (1989), Harrison *et al.* (1997), Kemp & Calburn (1987), Kemp & Kemp (1998), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Malherbe (1996), Penry (1994), Pickford *et al.* (1989), Pinto (1983), Prigogine (1983, 1985b), Short *et al.* (1990), Snow (1978), Steyn (1979, 1982, 1984, 1994b), Vincent (1990), Zimmerman, D.A. *et al.* (1996).

148. Chestnut Owlet

Glaucidium castaneum

French: Chevêchette châtaine **German:** Kastanienkauz **Spanish:** Mochuelo Castaño
Other common names: Chestnut Barred Owlet; Lake District/Ituri Owlet (*castaneum*)

Taxonomy. *Glaucidium castaneum* Neumann, 1893, Andundi, Zaire.
Has been suggested as forming superspecies with *G. capense* and *G. albertinum*. Has been treated as conspecific with *G. capense*; or sometimes disjunct race *etcheopari* alone placed with latter or even treated as separate species on grounds of distribution and ecology. Two subspecies recognized.

Subspecies and Distribution.

G. c. etcheopari Éard & Roux, 1983 - patchily in Liberia and Ivory Coast.

G. c. castaneum Neumann, 1893 - NE Zaire (Semliki Valley) and SW Uganda (Bwamba Forest).

Descriptive notes. 20-22 cm; c. 100 g. Pale facial disc with few darker rings, white eye-brows; head dark brown, densely spotted buffish; upperparts dark chestnut-rufous, scapulars and lesser wing-coverts with broad white edges; flight-feathers barred buff, 9-10 pale bars on tail; upper chest white with brown barring; belly with numerous dark spots; yellow eyes and bill. Differs from *G. albertinum* in usually more white on scapulars and wing-coverts. Juvenile undescribed. Race *etcheopari* smaller, upperparts dark with paler bars. **Voice.** Series of whistled "kyurr-kyurr-kyurr" notes, accelerating at end.

Habitat. Humid lowland, transitional and montane forest, at 1000-1700 m above sea-level; in W Africa (*etcheopari*), not uncommon in old secondary forest and even heavily logged forest.

Food and Feeding. Small vertebrates and large insects. Hunts mostly from perch.

Breeding. No information.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. Status of nominate race uncertain. W African population isolated; considered uncommon to locally not uncommon in Liberia, and widespread and common in Ivory Coast; likely to occur in Ghana, requires investigation.

Bibliography. Brown (1977), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1998a), Éard & Roux (1983), Fry *et al.* (1988), Gatter

(1988, 1997), Grimes (1987), Kemp & Kemp (1998), Lippens & Wille (1976), Mackworth-Praed & Grant (1970), Morel & Chappuis (1992), Prigogine (1983), Snow (1978), Thiollay (1985).

149. Albertine Owlet

Glaucidium albertinum

French: Chevêchette du Graben **German:** Albertseekauz **Spanish:** Mochuelo del Alberto
Other common names: Prigogine's Owlet

Taxonomy. *Glaucidium albertinum* Prigogine, 1983, Musangakye, Zaire.

Has been suggested as forming superspecies with *G. capense* and *G. castaneum*. Monotypic.

Distribution. Albertine Rift in E Zaire and N Rwanda.

Descriptive notes. c. 20 cm; female 73 g. Upperparts maroon-brown; forehead and nape with cream spots, leading to cream bars on upper mantle; scapulars with beige edges; back and uppertail-coverts unmarked; flight-feathers brown with pale brown bars; dark tail with c. 7 narrow cream bands; upper chest maroon-brown with broad cream bars, rest of underparts white with maroon-brown spots. Differs from *G. capense* in distinctly spotted head, plain back; and from *G. castaneum* in less white on scapulars and wing-coverts. Juvenile undescribed. **Voice.** No information.

Habitat. Montane forest, from c. 1000 m to 1700 m.

Food and Feeding. Stomach of 1 bird contained a beetle and a grasshopper.

Breeding. No information.

Movements. Unknown; probably resident.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species; present in Albertine Rift Mountains EBA. Surviving numbers not known, but small number of specimens collected from an area well explored by ornithologists suggests that it is rare. Known from 5 specimens: 2 collected at Lundulu in E Zaire, and 1 each from Nyungwe Forest in Rwanda, Musangakye and Munga in Itombwe Mts. Presumably declining as result of forest clearance. Mountain forest W of L Edward and Nyungwe Forest in Rwanda have both been reduced in size. Kamituga has become an important mining centre, and possibility of clearance and economic exploitation in Itombwe Mts could become a major threat. Forest conservation plans have been prepared to protect mountains W of L Edward and Nyungwe Forest, although whether local authorities will implement them is uncertain.

Genus *XENOGLAUX* O'Neill and Graves, 1977

150. Long-whiskered Owlet

Xenoglaux loweryi

French: Chevêchette nimbée German: Peruanerkauz Spanish: Mochuelo Peludo

Taxonomy. *Xenoglaux loweryi* O'Neill and Graves, 1977, 10 km northeast of Abra Patricia (1890 m), Departamento San Martín, Peru. Relationships unclear. Monotypic.

Distribution. N Peru (Río Mayo valley, NW San Martín).

Descriptive notes. 13-14 cm; one male 47 g, two females 46 g and 51 g. Distinctive, tiny, very short-tailed owl. Unique long "whiskers" around base of bill and on sides of facial disc, extending well beyond edge of face; plumage mainly warm brown, with few whitish spots above, short white eyebeams; belly with numerous thin whitish vermiculations; eyes orange-brown, bill greyish with yellow tip; tarsus and toes bare, pinkish. Juvenile undescribed. **VOICE.** No definite information; recent records suggest song possibly short, mellow whistles followed by faster, higher notes.

Habitat. Humid cloudforest with epiphytes and dense undergrowth, at c. 1900-2200 m.

Food and Feeding. Presumably insects. Apparently active at dusk.

Breeding. No information.

Movements. No information. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Andean Ridge-top Forests EBA. Currently considered Near-threatened. Perhaps not uncommon within restricted range; no data on current numbers, which assumed to be small. Only 3 specimens known. Major threat comes from habitat loss; forest destruction in restricted area in which species found appears to be continuing. With nothing known about this owl's ecology and biology, conservation measures difficult to determine; much further research needed.

(1977), Cardiff & Rensen (1994), Clark & Mikkola (1989), Collar *et al.* (1992), Davies *et al.* (1994, 1997), Fjeldså & Krabbe (1990), O'Neill & Graves (1977), Parker *et al.* (1982), Shuker (1993), Stattersfield *et al.* (1998), Stephens & Traylor (1983), Stotz *et al.* (1996), Wege & Long (1995).

Genus *MICRATHENE* Coues, 1866

151. Elf Owl

Micrathene whitneyi

French: Chevêchette des saguaros German: Elfenkauz Spanish: Mochuelo de los Saguaros

Taxonomy. *Athene whitneyi* Cooper, 1861, Fort Mojave, Arizona.

Relationships unclear. Races *whitneyi* and *sanfordi* appear to intergrade in NW Mexico and S Arizona. Four subspecies recognized.

Subspecies and Distribution.

M. w. whitneyi (Cooper, 1861) - breeds SW USA (extreme S Nevada, SE California, C Arizona, SW New Mexico and SW Texas) S to NW Mexico (Sonora).

M. w. idonea (Ridgway, 1914) - S Texas S to C Mexico (S to Puebla, W to Guanajuato).

M. w. sanfordi (Ridgway, 1914) - S Baja California and parts of Mexican mainland.

M. w. graysoni Ridgway, 1886 - Revillagigedo Is (Socorro I).

Descriptive notes. 13-14 cm; 41 g. Distinctively small. Face and throat cinnamon to cinnamon-buff, supercilia white with narrow black tips; upperparts brownish-grey to greyish-brown with distinct buff or pale tawny spotting, spots bigger and somewhat darker on forehead; lower hindneck with narrow white collar; outer webs of scapulars mostly white, margined terminally with black; flight-feathers and wing-coverts spotted; tail with usually 4-5 pale brown-buff or buff-white bands; underparts mixed white, grey and dull pale cinnamon or buffy-brown; bill and legs pale horn; eyes lemon-yellow. Distinguished from

Glaucidium brasilianum by shorter tail, rufous-brown upperparts, and inactivity during daylight hours. Juvenile has crown deep brownish-grey, lacks warm cinnamon-buff tone on face or throat, underparts lack buff-brown and are marbled or clouded white and light brownish-grey and barred dark brown. Race *idonea* greyer above; *sanfordi* darker below; *graysoni* tinged olive above, with more cinnamon below and on tail. **VOICE.** High-pitched calls, 5-15 or more, reminiscent of yelping puppy; may be repeated for long periods (male advertisement).

Habitat. Cactus desert, riparian woodland, dry oak woodland, wooded canyons, mesquite; most abundant and widespread in riparian broadleaf forest. In SC Arizona, shows wide habitat tolerance, occurring in nearly all plant communities with arborescent vegetation, at up to 2000 m elevation;

elsewhere in SW USA, mainly in wooded or forested riparian corridors and adjacent arid hillsides, below 1900 m.

Food and Feeding. Entirely arthropods, primarily insects. In Arizona, noctuid moths and crickets (Orthoptera) dominated diet until summer rains, when beetles (*Phyllophaga*) became primary food; scorpions (*Jevois*) also important prey there, eaten after stingers removed; arachnids may be significant component of food of nestlings, perhaps comprising as much as half of total; diet varies seasonally with changes in insect availability. Obtains sufficient water from prey. Mainly crepuscular, with some nocturnal foraging. Hunts by flying over open ground, hovering above ground and capturing prey as they take flight; also pursues prey on ground, or hawks flying insects, making capture with feet. **Breeding.** Season May-Jun in USA, Mar-Aug in Mexico. Pair formation begins as soon as female arrives back; little known of bonding patterns or pair-forming behaviour. Nest almost exclusively in cavity excavated by woodpecker, such as Acorn and Gila Woodpeckers (*Melanerpes formicivorus*, *M. uropygialis*) and flickers (*Colaptes auratus*, *C. chrysoides*), in various trees and cacti, including sycamore (*Platanus*), cottonwood (*Populus*), walnut (*Juglans*) and saguaro (*Carnegiea gigantea*); frequently selects cavity in dead branches; cavity apparently offers some refuge from high temperatures, particularly in deserts. 1-5 eggs; incubation 21-24 days; first 2 eggs usually hatch about same time and third a day later, suggesting that incubation normally begins with laying of second egg; female incubates and broods; male feeds female, who passes food to young; fledging period 28-33 days; young apparently able to capture insects, such as crickets, as soon as they can fly. In Arizona, of average clutch size 2-6 eggs, 1-9 eggs hatched and 1-8 young fledged. First breeding at c. 1 year. **Movements.** N populations migratory, leave by mid Oct, winter in N & C Mexico in areas with abundance of insects and other arthropods; males precede females on spring migration, arriving in breeding areas from mid Feb to Apr. Resident in Baja California and on Socorro I.

Status and Conservation. Not globally threatened. CITES II. In Mexico, fairly common to common, but local; no indication of numbers. Almost extirpated in California, where classed as endangered by California Department of Fish and Game; however, species not included on federal or state lists of endangered and threatened species, nor under review for such listing. In California, desert habitat heavily damaged by damming of Colorado R and subsequent agricultural development, with disappearance of many old trees and cacti in which birds nested; by 1978, estimated 10 pairs remained in desert. Attempt has been made to replace lost habitat by planting native sycamores, cottonwoods and mesquite along new banks of Colorado R; also, in 1983-87 owl project, 13 individuals bred in captivity and total of 21 released into California; population in 1987 probably did not exceed 25 pairs. Considerable decline along Rio Grande valley in S Texas since late 19th century, although in SW Texas range expanding N. In Arizona, populations around metropolitan areas have probably decreased. In general, these distributional changes reflect human-induced loss of habitat, compounded in Texas by long-term climatic changes. Species may become endangered throughout US range in near future because riparian forest rapidly declining in SW as result of overgrazing, flood scouring, dewatering and streamflow regulation; clearance of riparian woodland for agriculture and homes particularly extensive in SE Texas. Population depends directly on availability of insect prey and woodpecker nest holes; competition for cavities with Common Starlings (*Sturnus vulgaris*) may negatively affect some populations. Research and management recommendations include surveys to locate additional breeding areas; developing a co-ordinated programme to monitor populations; acquiring conservation easements or obtaining landowner conservation agreements for Colorado R and Rio Grande Basin and restoring riparian forest along these rivers; maintaining riparian woodland in W Arizona drainage areas; maintaining instream flow, regulating or excluding livestock grazing and timber cutting, and seasonally closing sensitive areas to public access; and incorporating natural landscaping in housing developments in Arizona.

Genus *ATHENE* Boie, 1822

152. Little Owl

Athene noctua

French: Chevêche d'Athéna German: Steinkauz Spanish: Mochuelo Europeo

Taxonomy. *Strix noctua* Scopoli, 1769, Krain, Carniola.

Probably forms subspecies with *A. brama*. Race *lilith* shown in recent studies to differ in DNA and vocal patterns, may be separate species. Many races considered probably intermediate populations or reflection of individual variation, while geographical subspecific boundaries obscure, with intergrading populations: *vidalii* and *indigena* intergrade over wide area in NW Russia; *noctua* intergrades with *vidalii* over wide area from S France E to Czech and Slovak Republics and with *indigena* in former Yugoslavia; *indigena* and *vidalii* intergrade in N Ukraine, Belarus and C Russia; *lilith* intergrades with *saharae* in Saudi Arabia and with *bactriana* in Iraq, Corsican and Sardinian birds perhaps warrant subspecific status (as *sarda*). Proposed races *kesleri* and *caucasica* synonymous with *indigena*; *solitudinis* synonymous with *saharae*. Thirteen subspecies recognized.

Subspecies and Distribution.

A. n. vidalii A. E. Brehm, 1857 - W & N Europe (S Baltic S to Iberia, including Balearic Is) E to NW Russia.

A. n. noctua (Scopoli, 1769) - C Europe (from about S Germany) S to Sardinia and Sicily, E to Romania.

A. n. indigena C. L. Brehm, 1855 - Albania, SE Yugoslavia, S & E Romania, S Ukraine, S Russia, Caucasus and SW Siberia, S to Crete, Turkey (except SE) and Middle East (S to Haifa).

A. n. glaux (Savigny, 1809) - N Africa, and coastal Israel S from Haifa.

A. n. saharae (Kleinschmidt, 1909) - N & C Sahara (S to Mauritania, Mali, Niger, Chad and Sudan). E discontinuously into Arabian Peninsula.

A. n. spilogastra (Heuglin, 1869) - E Sudan, N Ethiopia.

A. n. somaliensis Reichenow, 1905 - E Ethiopia, Somalia.

A. n. lilith Hartert, 1913 - Cyprus, and inland Middle East from SE Turkey S to S Sinai.
A. n. bactriana Blyth, 1847 - from SE Azerbaijan, E Iraq, Iran and Afghanistan E through C Asia to L Balkhash.
A. n. orientalis Severetzov, 1873 - extreme NW China and adjacent Siberia.
A. n. impasta Bangs & J. L. Peters, 1928 - Kokonor, W Gansu.
A. n. ludlowi Stuart Baker, 1926 - SC China and S & E Tibet, S to N Himalayas.
A. n. plumipes Swinhoe, 1870 - NE China, Mongolia and Ussuriland.
 Introduced (*vidalii*), just outside natural range, to Britain; also introduced (*vidalii*) to New Zealand.

Descriptive notes. 21-23 cm; wingspan 54-58 cm; male c. 162-177 g, female c. 166-206 g (*vidalii*). Compact, plump and relatively small, with wings broad and rounded; flight undulating, with alternating bouts of flapping and closing wings. Plumage colour variable, from grey-brown or rufous-brown to ochre-buff; upperparts spotted white, underparts splashed; facial disc obvious on dark birds; eyes bright yellow; bill pale yellow; legs proportionately long, feathered, pale yellowish to white. Distinguished from *A. brama* by slightly larger size, absence of bold barring on underparts; from *Glaucidium passerinum*, *Aegolius*

funereus and smaller *Otus* species by more boldly spotted appearance, lack of ear-tufts or sharp corners to head, and distinctive calls and flight. Juvenile distinctly paler and much more uniformly patterned than adult; spots buff, not white, and streaking narrower and paler brown. Races differentiated by colour and size: *vidalii* darkest, dark umber-brown above with white flecking on crown and white spotting on mantle, scapulars and larger wing-coverts, sepia flight-feathers, ground colour of underparts white but with black-brown band across throat and broad dark brown splashing and streaking on lower breast and body, better-marked facial disc with white on edges of crown, around outer cheeks and under bill and eyes, but dusky from bill through eye and in half-circle in centre of cheeks; *lilith* palest, pattern similar to *vidalii* but with pale buff upperparts and extensive white markings; other races intermediate. Voice. Male advertising call a mellow hoot, "goook", rising sharply in pitch at end, but that of *lilith* without upward inflection; loud "hoo", sometimes in crescendo series of 4-10 (up to 60), about 12-20 calls per minute; various other calls.

Habitat. Wide variety of semi-open habitats from steppes and stony semi-desert to farmland and open woodland, villages and urban areas, but extending to boreal and tropical areas; tends to avoid tall and dense stands of trees and any dense vegetation, even margins or enclaves between forests; frequently perches on post, tree or telegraph wire, or even building, particularly isolated one.

Food and Feeding. Largely small mammals and birds, reptiles, amphibians, beetles, crickets (Orthoptera), earwigs (Dermaptera) and earthworms (Lumbricidae). In Germany, insects and other invertebrates comprised 72% of diet, in Netherlands 89-2%, in France 94%, in Spain 96%, and in Italy 98%; proportion of invertebrate food increases gradually from C Europe to Mediterranean, probably result of increasing scarcity of vole (*Microtus*) prey in Mediterranean community. Perhaps deliberately takes plant material, chiefly grass and other leaves but including small fruits, berries and maize (*Zea*). Hunting essentially nocturnal and crepuscular, mainly dusk to midnight, then break of 2 hours before resumption to dawn; rarely diurnal. Hunts by perching on post or similar vantage point, dropping on prey; occasionally hovers; also hunts on ground, can run rapidly while chasing prey; larger prey taken with feet, smaller prey with bill. Beetles swallowed whole or sometimes held up in foot to be bitten 2-3 times; earthworms swallowed in single snap; prey accumulations presumed to be true caches of 30 or more items recorded.

Breeding. Season Mar-Aug. Monogamous, pair-bond often persisting all year and perhaps until partner dies. Nest in cavity, hole cleaned and hollow scraped; recorded sharing nest tree with Common Barn-owl (*Tyto alba*), also sharing hollow tree with Common Kestrel (*Falco tinnunculus*) and Common Wren (*Troglodytes troglodytes*); accepts nestboxes; some nest-sites in Britain used for over 25 years. 3-6 eggs, usually laid at 2-day intervals; lost clutches not often replaced; incubation 28-33 days, by female, reports of male incubating require confirmation; hatching either asynchronous or nearly synchronous; chick with grey-mottled down; female broods until young 14 days old, leaving nest only for brief periods, relying on male for food, both sexes leading after 14 days; young sometimes leave nest before fledging, hide in surrounding vegetation, fledge generally at 30-35 days, cared for and fed by both parents for 1 month after. In Germany, average 4.2 eggs/clutch recorded, average 2.4 young left nest hole, breeding success 58%; in Germany and Netherlands, mortality in first year of life 70%, annual adult mortality 35%; second broods rare.

Movements. Essentially resident; first-year birds disperse somewhat, but most settle within 20 km of natal site. Accidental Ireland (from introduced British population), Norway, Sweden, Finland, Estonia, Malta and Canary Is.

Status and Conservation. Not globally threatened. CITES II. Best current (mid 1990's) population estimates for Europe, expressed as number of breeding pairs: Iberia 88,000; Italy and France each 22,000; Britain 9000; Netherlands 11,000; Germany 7000; E & SE Europe 90,000; Russia up to 100,000; Turkey perhaps 20,000. In prime habitats such as in the French Massif Central and around the Black Sea, densities may reach 2-2 pairs/km². No reliable data for rest of range. Population fluctuates, especially in N of range, where marked decreases recorded after severe winters. Range has contracted locally in many parts of Europe, ascribed mainly to habitat changes, including loss of suitable nest-sites and, less often, pesticides; decreases reported in Britain, France, Belgium, Netherlands, Luxembourg, Germany, Denmark, Poland, Czech Republic, Slovakia, Austria, Switzerland, Italy and Greece. Numbers in Netherlands declined by probably over 50% during 1970-90, qualifying species for national Red List; industrialized farming practices largely responsible, reducing foodstocks such as voles and earthworms. In Britain, humans caused 35 of 52 breeding failures (67%) by various means, including taking eggs, shooting, deliberately blocking nest chambers, and disturbance by machinery. In C Europe, pastures and meadows flanked by pollard trees afford ample nest-sites and hunting lookout posts, and year-round short herbage with plenty of invertebrate prey provides optimal habitat; however, carrying capacity can be prejudiced by intensification of agricultural methods, ground clearance, reduced availability of nest holes through tree-felling and demolition or repair of old buildings, excessive use of toxic chemicals, and road-traffic deaths; such injurious factors can be partially offset by conservation, and where necessary by regular pollarding of old nesting trees and provision of nestboxes (as e.g. in Belgium and Germany) to replace lost natural holes. Species will adopt alternative nesting places, including crevices in ruins, windmills and adobe buildings.

Bibliography. 153. Spotted Owlet

Athene brama

French: Chevêche brame

German: Brahmakauz

Spanish: Mochuelo Brahmán

Other common names: Spotted Little Owl

Taxonomy. *Strix brama* Temminck, 1821, Pondicherry.

Probably forms superspecies with *A. noctua*. Birds from NE Assam sometimes separated subspecifically as *ultra*. Putative Tibetan form "*poikila*" apparently referable to *Aegolius funereus*. Four subspecies recognized.

Subspecies and Distribution.

A. b. albida Koelz, 1950 - S Iran and S Pakistan; possibly also S Afghanistan.

A. b. indica (Franklin, 1831) - N & C Indian Subcontinent.

A. b. brama (Temminck, 1821) - S India.

A. b. pulchra Hume, 1873 - Myanmar, Thailand (except S half of peninsula), S Laos, Cambodia and S Vietnam.

Descriptive notes. 19-21 cm; c. 115 g. Rounded head, with heavily spotted crown, darkish facial disc bordered white around sides; curved white eyebrows; above, grey-brown with scattered white spots; flight-feathers and wing-coverts mottled or spotted white; short tail narrowly and rather indistinctly banded, lacking conspicuous white tip; breast creamy-white with short dark grey to brownish bars; broad white gorget; tarsi long and thin, with short feathers to base of toes; iris golden-yellow; bill greenish-horn, yellow on culmen; feet yellowish-green. Differs from *A. noctua* in boldly barred underparts and slightly

smaller size. Races distinguished by colour intensity and size: *pulchra* small, dark, with heavier spotting; *indica* paler and browner; *albida* palest. Voice. Medley of harsh screeches, chatters and chuckles; breeding call "chiurr chiurr chiurr..." interspersed with "cheevah cheevah cheevah..."; sometimes discordant duets; territorial call plaintive double whistle, "plew plew"; non-breeding call "chevak-vak-cheevak-vak-vak-vak...", separately or interspersed with "chev-vuv-vuv-chev-vuv-vuv...", and "sev-sev-sev..."; aggressive call sounds like normal call but higher-pitched; alarm loud screeches.

Habitat. Towns, agricultural fields, open forest, desert and semi-desert, and mango groves, from lowlands to 1500 m; avoids dense forest.

Food and Feeding. Mainly small insects; also small roosting birds, mice, shrews (Soricidae) and geckos (Gekkonidae). Rodents comprise 61% of biomass but only 15% of prey items. Leaves roost c. 15 minutes after sunset. Hunts mainly from perch; occasionally hovers before swooping on prey; several individuals sometimes congregate at night while hunting insects near electric lights.

Breeding. Lays Dec-Apr; peak months vary annually, probably dependent on food availability or photoperiod. Nest in tree cavity, chimney, under ceiling or roof, in loft or eaves; appropriates cavities from mynas (Sturnidae), especially *Acridotheres*, parakeets (*Psittacula*) and rollers (*Coracias*); reported sometimes to line nest with feathers of other species; copulation occurs in twilight. Incubation behaviour begins before eggs laid. Usually 2-3 eggs (up to 5); female incubates, sits tight when nest approached, male also said to incubate but confirmation required; incubation period 28-32 days; eggs hatch synchronously; both male and female feed nestlings; no evidence of nest sanitation, faecal sacs and broken eggs left in nest; fledging period c. 32 days, young remain with adults for 3 weeks after fledging, often seen in family groups of 3-4. Nest success 50-65%.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Tolerates human activity and habitation, calling from roofs of houses and hunting around street lights. Common over most of range, though rare in S Vietnam.

Bibliography. Ali (1996), Ali & Ripley (1981), Allen (1920), Balasubramanian (1990), Brahmachary *et al.* (1972), Daniels (1997), Deignan (1945), Delacour & Jabouille (1940), Dubale & Rawal (1968), Eates (1939), Evans (1994), Grimmett *et al.* (1998), Hue & Échécopar (1970), Inskipp & Inskipp (1991), Jain & Advani (1983), Khajuria (1971), Kumar (1983, 1984, 1985), Kumar & Ramana Rao (1984a, 1984b), Lamba & Tyagi (1976), Lekagul & Round (1991), Mahabal & Lamba (1987), Majumdar *et al.* (1992), Mukherjee (1995), Porter, Christensen & Schiermacker-Hansen (1996), Ripley (1938), Ripley (1976, 1982), Roberts (1991), Scherzinger (1990), Smythies (1986), Stocks (1996), Suresh Kumar & Ramana Rao (1984), Voous (1988), Yang Lan & Li Guiyuan (1989), Zhao Zhengjie (1995).

154. Forest Owlet

Athene blewitti

French: Chevêche forestière

German: Blewitkauz

Spanish: Mochuelo de Blewitt

Other common names: Indian Forest Owlet, Forest Spotted Owlet/Owl, Forest Little Owl, Blewitt's Owl

Taxonomy. *Heteroglaux Blewitti* Hume, 1873, Busnah, Phooljan State, India.

Relationships uncertain; possibly more closely related to *Glaucidium*. Monotypic.

Distribution. WC & EC India: plains and low foothills of Akran Range (W end of Satpura Mts) near Tapi (Tapti) R in NW Maharashtra (formerly W Khandesh), and probably in E Madhya Pradesh and W Orissa (no records in 20th century from last two).

Descriptive notes. 20-23 cm. Facial disc mostly white with fine light brown barring; crown grey-brown with faint, sparse pale spots (appears unspotted); mantle and back unspotted dark grey-brown, with obsolete hind-collar; brown scapulars marked with large white spots; flight-feathers and tail with broad bars of dark brown and white, tail broadly tipped white except in worn plumage; below, mostly white, with dark brown bar across throat; breast almost uniform grey-brown, upper flanks broadly barred dark brown, lower breast, belly, lower flanks, heavy tarsal feathering and undertail-coverts white; iris yellow; bill yellowish or

greenish-horn. Flight direct, not undulating. Differs from other *Athene* in relatively short broad wings, very heavy tarsi, large claws; distinguished from adult *A. brama* by lack of spotting on head, and from all ages of latter by plumage more uniform above and more contrasting below and on wings and tail, different face pattern and heavily white-feathered toes. Juvenile undescribed. Voice. Primary song a series of quick, sweet, plaintive well-spaced notes of 1-2 syllables, given by day; also hissing and screeching calls.

Habitat. Dry to dense moist lowland deciduous forest at 200-500 m; once found in a streamside mango grove. Often perches in shady middle stratum of forest in hot weather.

Food and Feeding. Little information; 1 of 2 individuals seen in Nov 1997 had blood on bill, indicating that vertebrates (mammals or birds?) probably form part of diet, although not much harassed by small birds, which show little fear of it; also observed eating a fair-sized lizard by day, and foraging on rain-soaked ground, presumably for insects. Strongly diurnal; perches in bare tree-tops in full sun, flicking tail.

Breeding. No information.

Movements. Apparently resident; birds were still present at the Nov 1997 rediscovery site in Jun 1998 and subsequently.

Status and Conservation. CRITICALLY ENDANGERED. CITES I. Only 7 skin specimens, indicating historical rarity; last collected in 1884 from Taloda (Khandesh); claim of specimen collected in 1914 recently shown to be fraudulent. Presumed extinct until claim of 1 photographed in 1968 near Nagpur, Madhya Pradesh, but this subsequently rejected as misidentified *A. brama*; several other photographs and sight records since 1950's from S Rajasthan and S Bihar either misidentified or unsatisfactory. Unsuccessful searches in 1975-76 in 3 areas along Tapi (Tapti) R and 2 in Orissa, and in 1997 in 4 areas in E of range. No indisputable records until 2 birds (possibly pair) seen, photographed and videotaped in Nov 1997 near Shahada, N of Tapi R. Clearly threatened by habitat destruction, as it is thus known only from lowland forest in areas with increasing human pressure.

155. Burrowing Owl

Athene cunicularia

French: Chevêche des terriers **German:** Kaninchenkauz **Spanish:** Mochuelo de Madriguera

Taxonomy. *Strix Cunicularia* Molina, 1782, Chile.

Sometimes placed in separate monotypic genus *Speotyto* on basis of morphological and karyotypic differences, but osteological features and DNA support inclusion in *Athene*. Some of the races described could reflect merely individual variation or intergrading populations, and thus probably not acceptable; subspecific taxa and delimitations require critical re-evaluation with modern systematic methods, although some certainly appear distinct. Lesser Antilles races *amaura* and *guadeloupensis* extinct. Nineteen extant subspecies recognized.

Subspecies and Distribution.

- A. c. hypugaea* (Bonaparte, 1825) - from S Canada, W of E edge of Great Plains, S to El Salvador.
- A. c. rostrata* (C. H. Townsend, 1890) - Clarion I in Revillagigedo Is (off W Mexico).
- A. c. floridana* (Ridgway, 1874) - Florida (also, marginally, Georgia) and Bahamas; also (possibly this race) Cuba and I of Pines.
- A. c. troglodytes* (Wetmore & Swales, 1931) - Hispaniola, including Gonâve I and Beata I.
- A. c. arubensis* (Cory, 1915) - Aruba (Netherlands Antilles).
- A. c. brachyptera* (Richmond, 1896) - Margarita I, off N Venezuela.
- A. c. apurensis* (Gilliard, 1940) - NC Venezuela.
- A. c. minor* (Cory, 1918) - S Guyana and extreme N Brazil (Roraima).
- A. c. carrikeri* (Stone, 1922) - E Colombia.
- A. c. tolimae* (Stone, 1899) - W Colombia.
- A. c. pichinchae* (von Boetticher, 1929) - W Ecuador.
- A. c. punensis* (Chapman, 1914) - SW Ecuador, NW Peru.
- A. c. intermedia* (Cory, 1915) - W Peru.
- A. c. nanensis* (Berlepsch & Stolzmann, 1892) - SW Peru.
- A. c. juninensis* (Berlepsch & Stolzmann, 1902) - C Peru to W Bolivia and NW Argentina.
- A. c. boliviana* (L. Kelso, 1939) - Bolivia.
- A. c. grallaria* (Temminck, 1822) - C & E Brazil.
- A. c. partridgei* Olog, 1976 - NE Argentina (Corrientes).
- A. c. cunicularia* (Molina, 1782) - S Bolivia and S Brazil S to Tierra del Fuego.

Descriptive notes. 19-25 cm; male 130-185 g, female 120-250 g. Head round; distinct oval facial ruff, broad buff-white eyebrow to malar stripe; upperparts brown, with crown, back and scapulars spotted pale brown-buff to buff-white; wings long and rounded, with 10 brown and buff-white barred primaries; tail short, with 12 similarly barred rectrices; underparts buff-white with broad brown barring, throat and undertail-coverts white; eyes lemon-yellow, bill cream; legs long, with white to beige feathers, toes bristled. Sexes similar; female more heavily barred below, male slightly lighter and dorsally more grey-brown during summer. Juvenile brown above, streaked or spotted buff-white, with band of unspotted brown feathers between

nape and back; dark brown ground colour on anterior wing and tail contrasts with lighter median secondary coverts, producing light band on upperwing; chest dark brown. Races vary mainly in biometrics, in depth of coloration and in strength and extent of markings; suggested that W North American races larger than Caribbean and tropical ones, but datasets for *floridana* and *hypugaea* show little difference; *grallaria* with much buff in plumage. Voice. "Coo coooo" given exclusively by male; male also gives series of 5-8 high-pitched and raspy "chéh" notes, first longer, followed by longer pause, and the rest close together, rather rhythmically, lasting c. 1-2 seconds in total; female copulatory call is series of downslurred notes or warble.

Habitat. Dry and open habitats: treeless plains, grassland, prairie, savanna, desert or farmland; golf courses, cemeteries, road verges (even within cities), airports, vacant lots in residential areas, campuses and showgrounds; from sea-level to 4500 m. Often associated with burrowing animals: for most populations, burrow a critical habitat requirement, though some excavate own burrow (e.g. in Florida). **Food and Feeding.** Primarily arthropods and small mammals; also amphibians and reptiles. In Oregon, invertebrates made up 91.6% of diet by number but only 22% by weight; small vertebrates, mostly mammals, comprised 8.4% of individuals and 78% of biomass. In Arizona, scorpions (Scorpionida), beetles (Coleoptera), cicadas (Cicadidae) and small rodents (Heteromyidae) most frequent in summer pellets. In California, beetles, crickets (Orthoptera) and meadow voles (*Microtus*) most frequent, and earwigs (Dermaptera) common both winter and early summer; however, pellets can be poor indicators of food habits, given differences in way prey consumed or rate at which remains decomposed. In Florida, amphibians and reptiles especially important. Crepuscular, though hunting over 24 hours observed; insects taken during daylight, small mammals after dark. Hunts by walking, hopping or running along ground; also flies from perch, hovers over tall vegetation, and flycatches in air; hunting style connected to type and activity of prey, time of day and vegetative substrate. Prey caught with feet; may be transferred to bill for carrying or presentation to young; food items also sometimes found in nest burrow or tunnel during breeding season, or in food caches scattered through hunting area.

Breeding. Season Mar-Aug. Monogamous, occasionally polygynous; both pair-retention and pair-splitting observed; duration of pair-bond varies among races. Nest in burrow, either isolated or near other burrows, sometimes close to road, can be surrounded by bare ground or in grazed and level pasture, sometimes high perches nearby; in Florida often excavates own burrow, and sites concentrated in residential and industrial areas where development occupies 25-75% of landscape, with burrows typically in elevated areas, presumably to protect from flooding; in Caribbean too, will excavate hole where burrowing animals absent; in general, however, uses burrow dug by mammal such as ground squirrel (*Spermophilus*), American badger (*Taxidea*), prairie dog (*Cynomys*), marmot (*Marmota*), skunk (*Mephitis*, *Spilogale*), armadillo (*Dasypus*), kangaroo rat (*Dipodomys*), or by gopher tortoise (*Gopherus*); burrow renovated and maintained by digging and kicking backwards with feet, and digging with bill. Courtship displays include circular flights by male, mutual billing and preening of head and facial areas, presentation of food by male to female, and male song. Clutch c. 6-11 eggs; incubation 28-30 days; female does all incubating and brooding, male does all hunting, female begins to hunt as young become less dependent; chick partly covered with down (tilopaedic), altricial; fledging period c. 44 days; young stay in area of nest burrow and join parents on foraging flights at dusk. Fledging success in old burrows 63%, in newly excavated ones 19%; reproductive success varies from 100% of attempts (New Mexico) to 33% (California), 1.6-4.9 fledged per nest attempt; no information on lifetime reproductive success, though in California reproductive extinction observed in a population in half time predicted by population models. Age at first breeding 1 year. Longest known lifespan observed in ringed wild individual 8.6 years.

Movements. Most N populations migrate or disperse; little information on routes, times and wintering areas; those breeding in S Canada and N USA probably migrate S, those in SW & SC USA (New Mexico, Colorado, Texas, Oklahoma) migrate or disperse widely. Remaining populations breeding S from California and Florida essentially non-migratory.

Status and Conservation. Not globally threatened. CITES II. Listed as endangered in Minnesota and Iowa, and species of special concern in Washington, Oregon, California, Montana, Idaho, Wyoming, Utah, North and South Dakota, Oklahoma and Florida; designated as endangered in British Columbia and Manitoba, and threatened in Alberta and Saskatchewan. Still relatively numerous in parts of North American range (e.g. of 24 jurisdictions in W USA, 46% reported a population size between 1000 and 10,000 pairs in early 1990's), but declining seriously in many areas. Considered common to fairly common in Mexico; locally common in Cuba and Hispaniola, and fairly common in most of the Bahamas, but declining in Grand Bahama and New Providence; widespread and locally common in South America, though reported as virtually extinct in Tierra del Fuego. Race *amaura* of Nevis, St Kitts and Antigua and *guadeloupensis* of Guadeloupe and nearby Marie Galante extirpated c. 1890. In Florida, however, where population estimated 3000-10,000 adults in late 1980's, range expansion N to Georgia since 1950's; human activities actually beneficial where mowing, cattle grazing and wetland drainage have increased range, residential and industrial areas supporting largest concentrations. Activities causing decline include intensive cultivation of grassland and native prairies, resulting in 21% loss of habitat over 7 years in Saskatchewan; intensive agriculture, resulting in loss of burrows and foraging areas, degradation of nesting habitat, greater vulnerability to predation, and potential impeding of pair formation; collisions with vehicles; disturbance at nest- and roost-sites from dogs, people and construction work; shooting and trapping; and pesticides and other contaminants and toxins, resulting in either direct toxicity or indirect mortality from contaminated prey, though latter effect needs further study. Proposed management strategies include protecting burrowing-mammal populations, placing wood or plastic nestboxes in ground, providing artificial perches for hunting and predator observation, and managing vegetation through fire or grazing. In Canada, use of carbofuran insecticide already prohibited within 250 m of occupied nest burrows, though prohibition appears to be ineffective despite promotion; some Canadian provinces protect private land from cultivation and reseeded through monetary and voluntary lease agreements. In Florida, signs placed near burrows to educate public, but action did not significantly affect fledging and territory-reoccupancy rates. Reintroductions attempted in British Columbia, Manitoba and Minnesota; in British Columbia, 91 fledglings produced as of 1986, but no returns of reintroduced young recorded in either Manitoba or Minnesota.

Tribe AEGOLIINI

Genus AEGOLIUS Kaup, 1829

156. Boreal Owl

Aegolius funereus

French: Nyctale de Tengmalm **German:** Rauhfußkauz **Spanish:** Mochuelo Boreal
Other common names: Tengmalm's Owl

Taxonomy. *Strix funerea* Linnaeus, 1758, Sweden.

Races *pallens* and *magnus* intergrade in Yakutsk area; these populations sometimes separated as race *jakutorum*. Nominative and *pallens* intergrade in W Asia. Proposed race *sibiricus* included within *pallens*. "*Athene brama poikila*" apparently referable to present species. Six subspecies recognized.

Subspecies and Distribution.

A. f. funereus (Linnaeus, 1758) - Europe from N Scandinavia S to Pyrenees and then E to Urals, excluding Caucasus.

A. f. caucasicus (Buturlin, 1907) - Caucasus; possibly this race or nominate in N Turkey.

A. f. pallens (Schalow, 1908) - W Siberia, Tien Shan, and S Siberia E through NE China (Heilongjiang) to Russian Far East (including Sakhalin).

A. f. magnus (Buturlin, 1907) - NE Siberia, from Kolyma to Kamchatka.

A. f. heickianus Stresemann, 1928 - NW India (Lahul) and W China (Qinghai).

A. f. richardsoni (Bonaparte, 1838) - North America (from C Alaska S to W USA, and E through Canada to Labrador).

Descriptive notes. Male 21–25 cm, 90–115 g; female 25–28 cm, 120–195 g. Conspicuous grey-white facial disc, framed by brown-black border and highlighted by white raised eyebrows; crown umber-brown with numerous small white spots; upperparts brown, with large white spots on scapulars and small white spots on back and rump; primaries with no more than 5 rows of white spots; tail with 3 rows of spots remaining isolated even when tail closely folded; underparts creamy-white, broadly streaked brown to russet; eyes yellow; bill waxy yellow to horn; legs and toes thickly feathered to claws. Distinguished from *A.*

acadicus by larger size, yellow bill, stronger border to facial disc. Juvenile with upperparts completely dull chocolate-brown, underparts brown, facial disc dark brown with black fringe along border. Races differ mainly in coloration: in Eurasia, *magnus* largest and brightest; Nearctic *richardsoni* darkest race. **VOICE.** Male's primary advertisement a "staccato song", series of trills that increase in volume, resembling winnowing of Common Snipe (*Gallinago gallinago*); singing bouts frequently last 20 minutes but may extend to 2–3 hours.

Habitat. Boreal and subalpine forest and mixed woodland. In Europe, breeds in montane pine (*Pinus*), pine-spruce (*Picea*) and birch (*Betula*) forest, old forest stands with beech (*Fagus*), and coniferous forest with mature trees; in North America, occurs in forest characterized by black and white spruce (*Picea mariana*, *P. glauca*), aspen and poplar (*Populus*), birch and balsam fir (*Abies balsamea*), old aspen and mixed-forest sites, and subalpine forest characterized by subalpine fir (*A. lasiocarpa*) and Engelmann spruce (*Picea engelmannii*). In winter favours mature forest, where uncrusted snow facilitates access to prey; likewise, in summer, mature forest sites have less herbaceous cover than open sites, allowing greater access to prey. Following spring thaw, shifts to openings where vole densities exceed those in forested stands; sometimes hunts over clear-felled areas and agricultural fields.

Food and Feeding. Small mammals, birds and insects; diet includes shrews (*Sorex*), red-backed voles (*Clethrionomys rutilus*) and other voles (*Microtus*), Common Chaffinch (*Fringilla coelebs*), Nearctic thrushes (*Catharus*) and beetles. Nocturnal, except in N regions without summer darkness. A sit-and-wait predator, not a pursuer; moves through forest in zigzag pattern, flying short distances between perches; after detecting prey, waits 10 minutes or more before attacking (if prey not in vulnerable position); usually attacks prey within 10 m of perch. Can capture prey under snow or vegetation; ability to locate aurally attributed to extreme asymmetry of skull, which permits localization of sounds in vertical as well as horizontal direction. Smaller prey consumed whole (head first) or piecemeal; larger ones also eaten piecemeal, with head consumed first, beginning with rear of cranium and brain; sometimes discards stomach and intestines of red-backed voles before consumption.

Breeding. Season Mar-Jul. Monogamous, polygynous and polyandrous; cases of polygyny and polyandry coincide with peaks in vole numbers; pair-bond usually lasts 1 season. In North America, nest primarily in hole of Pileated Woodpecker (*Dryocopus pileatus*) or Northern Flicker (*Colaptes auratus*); in Europe, uses Black Woodpecker (*D. martius*) cavities and nestboxes; also natural site in stand of mature or older forest, but owing to removal of large trees and snags many populations now rely almost entirely on nestboxes (more than 90% in Fennoscandia). Male sings from 1–5 potential nest cavities; after attracting female to area, demonstrates from each cavity and apparently female chooses one. 3–6 eggs, occasionally up to 11, average clutch size from 3–25 (Idaho) to 5–6 (Finland); multiple clutches common in good vole years; incubation period 29 days; female incubates and broods; male feeds female during incubation, but rarely remains near nest while roosting or foraging, brings all food to nest for first 3 weeks, then female may help supply food; chicks hatch with short white down, eyes closed, cannot lift head or stand on feet; fledging period 28–36 days; fledglings remain within 100 m of nest in loose group for 1 week or more, utter begging calls after dark and fed by parents, with time move farther from nest, but fed by adults for at least 2 more weeks, reach independence 3–6 weeks after leaving nest cavity. In 2 good vole years,

bigamous males reared average 7.8 and 9.5 fledglings/male compared with 4.2 and 5.1 for monogamous males, but no difference in number of eggs or nestling mortality for biandrous versus monoandrous females; in Idaho, 10 of 16 nests produced no young, and successful nests produced average of 2.3 fledglings; in Finland, lifetime reproduction of 141 males averaged 5.2 fledglings, first-year male annual survival was 50% and adult male annual survival 72%. Sexual maturity and breeding within 1 year of hatching. Breeding males remain in breeding population 1.5 years, have lifespan of 3–5 years.

Movements. Generally year-round resident within stable home range, but disperses in years when prey scarce. May partially migrate: adult males resident, females and young migratory. In Finland, adult females disperse up to 580 km between successive breeding seasons, while males rarely move more than 5 km; during prey declines, more than half of all females in Sweden nomadic. Accidental in Britain; NE Siberian race *magnus* accidental in Alaska.

Status and Conservation. Not globally threatened. CITES II. Population estimates largely conjectural, even in Europe, owing to species' elusive nature and mostly nocturnal habits, and primary association with relatively inaccessible areas of coniferous forest. European strongholds in Sweden (10,000–40,000 pairs) and Finland (8000–20,000 pairs), with somewhat fewer in Norway, Baltic States and Belarus, and lesser numbers in scattering of countries from Spanish Pyrenees (discovered in late 1880's) to Poland and SE as far as Turkey (5–50 pairs) and Caucasus; no major declines reported. Russian population estimated at 10,000–100,000 pairs. Fluctuations in breeding populations increase to N and E, perhaps dependent not only on vole cycles (more important and more marked in N and E regions) but also on depth of annual snow cover, since feeding inhibited by deep snow. Nestboxes employed extensively in Europe to monitor demographic characteristics, e.g. by ringing nestlings, as well as to mitigate loss of nest-sites; c. 11,000 boxes installed in Finland from which fledglings ringed annually. In North America, lack of information on demography, local and regional populations and responses to habitat change makes assessment of conservation status difficult; designated "sensitive species" in USA (USDA Forest Service Regions 1, 2, 3 and 4). Indirect effects of forest-cutting probably greatest human influence: timber-harvesting can reduce primary prey populations, remove forest structure necessary for foraging, and eliminate nest cavities, but selective harvesting may allow tree removal while maintaining suitable habitat; current management in USA involves retaining large-diameter snags in clear-felled areas and establishing nestboxes to monitor populations, also retaining aspen for nesting. Long-term effectiveness of snag retention on clear-felled sites unknown. Because forest succession is slow in spruce-fir forest, management must acknowledge that clear-felled sites will remain unsuitable for roosting or foraging for up to a century, and new nest trees will not develop for up to 2 centuries.

Bibliography. 157. Northern Saw-whet Owl

Aegolius acadicus

French: Petite Nyctale **German:** Sägekauz **Spanish:** Mochuelo Cabezon
Other common names: Saw-whet Owl; Queen Charlotte Owl (*brooksi*)

Taxonomy. *Strix acadica* J. F. Gmelin, 1788, Nova Scotia.

Possibly forms superspecies with *A. ridgwayi*, although ranges appear to overlap in S Mexico (with apparent hybridization); perhaps conspecific with latter; further study needed. Proposed race *brodkorbi* from Sierra Madre in Oaxaca based on a single juvenile specimen. Two subspecies recognized.

Subspecies and Distribution.

A. a. acadicus (J. F. Gmelin, 1788) - from S Alaska S to S USA, E to SE Canada and N Florida; also highlands of Mexico from NE Sonora to C Michoacán, E in C highlands to Puebla, Hidalgo and C Oaxaca, with isolated population in SE Coahuila, SW Nuevo León and N San Luis Potosí.

A. a. brooksi (Fleming, 1916) - Queen Charlotte Is (British Columbia).

Descriptive notes. Male 18–20 cm, c. 75 g; female 20–21.5 cm, c. 100 g. Small owl with large, rounded head. Head greyish-brown, with white streaks on crown; facial disc round, white above and between eyes; upperparts warm brown, with white spots on nape, scapulars and wing-coverts; wings rounded, outer webs of outer primaries spotted with white along edge; tail short, with 2 or 3 interrupted narrow bands of white, and margined at tip with white; underparts white, tinged or suffused buff and broadly striped or spotted rufous-brown; eyes yellow to golden; bill black; legs short, heavily feathered to talons,

pale buff to cinnamon-buff. Differs from *A. funereus* in smaller size, no black edge to facial disc, black bill, streaked (not spotted) crown; from *Glaucidium californicum* in larger size, bigger head, relatively shorter tail, more conspicuous facial disc. Juvenile lacks white markings above, except on wings and tail, and has unmarked brown breast and buff belly, and black-brown facial disc with conspicuous Y-shaped white marking between and above eyes. Race *brooksi* darker and much less

spotted above, rich orange-buff below. VOICE. Male advertising call a monotonous series of whistled notes on constant pitch, about 2 per second; female version softer, less constant in pitch and amplitude; also short series of "ksew-ksew-ksew", like sound produced by filing (whetting) large mill saw.

Habitat. Woodland, with highest densities in coniferous forest at moderate elevations and latitudes. Occurs in red spruce (*Picea rubens*) forest in North Carolina, northern white cedar (*Thuja occidentalis*) and tamarack (*Larix laricina*) swamps and red pine (*Pinus*) forest in NE USA and SE Canada, and riparian areas characterized by large white spruce (*Picea glauca*), balsam poplar and aspen (*Populus*) copses in C Canada; also in deciduous riparian woodland amid shrub-steppe desert in SW Idaho. Relatively dense populations in lower- to middle-elevation forest of ponderosa pine (*Pinus ponderosa*), Douglas fir (*Pseudotsuga menziesii*), western red cedar (*Thuja plicata*), grand fir (*Abies grandis*) and western larch (*Larix occidentalis*); lower numbers in subalpine forest of Engelmann spruce (*Picea engelmannii*), lodgepole pine (*Pinus contorta* var. *latifolia*) and subalpine fir (*Abies lasiocarpa*), usually restricted to riparian situations. In winter, wide range of habitats, varying in altitude, latitude and vegetation type; various rural and even suburban environments. Presence of dense vegetation for roosting and perches for foraging seems critical. In Mexico, occurs at 1350-2500 m.

Food and Feeding. Small mammals, primarily deer mice (*Peromyscus*); also red-backed voles (*Clethrionomys rutilus*) and *Microtus* voles fairly common. Small birds eaten in low numbers, mostly during passerine migration when they are active at night; beetles (Coleoptera) and grasshoppers (Orthoptera) also taken; race *brooksi* along coast consumes considerable quantities of intertidal invertebrates, including amphipods, isopods, spiders and insects. Nocturnal, with occasional diurnal foraging. Hunts from perch on low branch, shrub or fence post, usually in forest opening and other habitat edges. Prey detected by excellent hearing and low-light vision; caught with feet and swallowed in pieces, starting with head; larger prey consumed as 2 meals; avian prey plucked before consumption.

Breeding. Season Mar-Jul. Monogamous; polygyny occurs where prey abundant; no evidence of pair-bond lasting more than 1 season. Uses nest cavity of woodpecker or nestbox; lays directly on wood chips or other debris in cavity, such as nest of squirrel (Sciuridae). Mated pairs engage in allopreening; male occasionally sings from suitable nest cavity. 5-7 eggs; second broods probably cases of sequential polyandry; female incubates and broods young; male feeds her throughout laying, incubation and brooding; incubation period 27-29 days; hatching asynchronous; chick emerges with eyes closed and with covering of white down; when youngest nestling about 18 days old, female leaves nest to roost elsewhere; male feeds young throughout, even after female leaves; after fledging, brood-members remain together outside nest, continue to be fed by male for at least 1 month. Hatching success 75% from 7 nests (30 eggs hatched from 40 laid); in British Columbia, 22 nests fledged 2-68 young/nest. Age of first breeding probably 1 year, though no data from wild populations; ringing returns indicate survival c. 40-50% per year. Longest recorded lifespan 7 years.

Movements. Present year-round in breeding range, but considerable numbers move S in autumn, at least in E North America; S movement begins Sept-Nov in E Canada and NE USA, and Oct-Nov farther S; females migrate earlier than males. Common routes are from C Ontario down Ohio R valley to Kentucky; from Atlantic coastal lowlands from Nova Scotia to North Carolina; and around L Superior from Minnesota to Wisconsin, then S and/or E; however, does not strictly adhere to these routes. In W, movements poorly documented, but probably altitudinal as well as latitudinal. Migrates throughout night, with peak movements on clear nights with W to NW winds after passage of cold front; migration suppressed by full moon and strong, gusty winds. Accidental Bermuda.

Status and Conservation. Not globally threatened. CITES II. World population conservatively estimated at 100,000-300,000 individuals. No data on trends, but probably declining slowly as habitat lost. Acceleration of logging rates in S Canada and N USA has undoubtedly reduced amount of suitable breeding habitat, particularly through loss of nesting snags; also, young regenerating forest often too thick, lacks edge habitat and open understorey favoured for foraging. In general, mature and old-growth stands seem favoured for breeding: 10 of 13 breeding-season roost-sites were in old-growth ponderosa pine and grand fir forest, despite more extensive searches in managed stands; winter habitat perhaps less critical. Seems to survive well in rural and semi-rural areas, which are extensive compared with breeding habitat, though further study needed. In terms of management, destruction of habitat, particularly nesting snags, represents greatest threat; nestboxes could mitigate loss of snags in areas that have been selectively logged or even clear-felled in small blocks; retention of woodlots in rural and residential areas would help migrating and wintering birds.

158. Unspotted Saw-whet Owl

Aegolius ridgwayi

French: Nyctale immaculé **German:** Ridgwaykauz **Spanish:** Mochuelo Moreno

Taxonomy. *Cryptoglaux ridgwayi* Alfaro, 1905. Cerro de la Candelaria, near Escazú, Costa Rica. Possibly forms superspecies with *A. acadicus*, although ranges appear to overlap in S Mexico (with apparent hybridization). Perhaps conspecific with latter; further study needed. Validity of races uncertain; suggested that both *tacananensis* and *rostratus* perhaps in fact hybrids between present species and *A. acadicus*; further research required. Three subspecies conditionally recognized.

Subspecies and Distribution.

A. r. tacananensis R. T. Moore, 1947 - S Mexico (Chiapas).
A. r. rostratus (Griscom, 1930) - Guatemala, Honduras and El Salvador (presumed this race).
A. r. ridgwayi (Alfaro, 1905) - Costa Rica and W Panama.

Descriptive notes. 18-21 cm; 80 g. Small, large-headed and variable in colour. Plumage recalls juvenile *A. acadicus*; facial disc brown, with paler central area and narrow outer rim; broad white eyebrows; upperparts uniform grey-brown, with white markings only on wings and sometimes tail; underparts brown, yellower on belly; toes feathered almost to talons. Juvenile similar, but plumage downier, often pale streaking on chest. VOICE. Whistled "hoo hoo hoo...", 4-10 notes; similar to *A. acadicus* (but distinguishable by sonograms).

Habitat. Humid pine-oak and oak forest of highlands and cloudforest; sometimes in edges and gaps with scattered tall trees; from 1600 m to 3000 m, occasionally down to 1400 m in Guatemala.

Food and Feeding. Probably mainly small mammals, such as rodents and shrews (Soricidae), also bats, and small birds; presumably insects, too; occasionally frogs. Hunts after dusk; fluttery and agile flight with rapid wingbeats.

Breeding. Little known. Lays during Mar; nest undescribed, probably old woodpecker hole; 5-6 eggs. **Movements.** Resident, but little known.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Generally considered uncommon. Fairly common (e.g. around San Cristóbal de las Casas, Chiapas) to uncommon in Mexico; occasional in some places in Costa Rica; rare in Panama. Needs at least patchy forest; suitable habitat decreasing. No information available on ecology or behaviour, and details of distribution very sparse.

Bibliography. Anon. (1998a), Binford (1989), Howell & Webb (1995a), Land (1970), Ridgely & Gwynne (1989), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Wetmore (1968a).

159. Buff-fronted Owl

Aegolius harrisii

French: Nyctale de Harris **German:** Blaßstirnkauz **Spanish:** Mochuelo Canela

Taxonomy. *Nyctale Harrisii* Cassin, 1849, South America.

Race *iheringi* perhaps specifically distinct. Population of Cerro Neblina (S Venezuela), known only from two specimens collected in 1985, has not been subspecifically determined. Three subspecies recognized.

Subspecies and Distribution.

A. h. harrisii (Cassin, 1849) - Andes from NW Venezuela S to NC Peru.
A. h. iheringi (Sharpe, 1899) - E Bolivia, Paraguay, C & E Brazil (Ceará to Rio Grande do Sul), S to NE Argentina and NE Uruguay.
A. h. dabbenei Olog, 1979 - NW Argentina (Tucumán, Salta and Jujuy); also (possibly this race) W Bolivia.

Also (subspecies unknown) Cerro Neblina, S Venezuela.

Descriptive notes. 20-21 cm; 104-150 g. Compact, with short tail and large square head. Facial disc outlined in black with buff trim, strongly contrasting with dark head; lores to base of bill brown; forehead and collar on hindneck yellowish-buff; upperparts chocolate-brown, darkest on head; primaries notched with white, wing-coverts with white spots; tail blackish, with 2 broken white bars and white tip; small chin patch brown. Rest of underparts yellowish-buff; eyes greenish-yellow; bill pale yellow to grey; tarsi feathered cream-yellow; toes unfeathered and yellowish. Juvenile lacks buff spots above. Race *dabbenei* darker above.

tinged cinnamon below; *iheringi* dark above, scapulars variably edged buff, face and underparts deeper orange. VOICE. Whistled trill, "frunrururururu", lasting 3-4 seconds, pitched high but slightly fluctuating.

Habitat. Recorded from fairly open, humid forest to tree-line, but also in drier zones and ravines, and at forest edge: examples include *Podocarpus* and *Alnus* forest, *Araucaria* forest, *Polylepis* woodland, dry Chaco deciduous forest, *cerrado* woodland, densely timbered *caatinga*, semi-humid, rather open forest about 10 m tall, and mossy, stunted forest near tree-line; also artificial landscapes rich in fruit trees and palms. In Andes, at elevations of 1500-3800 m; elsewhere in lowlands, from sea-level to 1000 m.

Food and Feeding. Prey remains found in nest cavity included chitin of insects and bones of small rodent. Record of individual seen hovering over roadside shrub before dawn. No further information.

Breeding. Little information. In Brazil, nest with 3 eggs found in early Mar 6 m above ground in cavity of dead palm, probably abandoned hole of parrot (*Aratinga*), cavity 60 cm deep and 15 cm in diameter, with opening 10 cm across, lined with cattle dung, feathers and hairs; in Argentina, found nesting in hollow tree.

Movements. Probably resident.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Considered generally rare throughout range, but very few data. Placed on preliminary "Blue List" in Colombia, where population believed to be declining. In Argentina, considered less scarce than generally supposed and probably overlooked: recent scattered records reported with some regularity from different parts of the country. Occurs in several protected areas, e.g. *Podocarpus* National Park, Ecuador, and Iguazú and El Rey National Parks, Argentina.

Bibliography. Genus *NINOX* Hodgson, 1837

160. Rufous Owl

Ninox rufa

French: Ninox rousse **German:** Rostkauz **Spanish:** Ninox Rojizo
Other common names: Rufous Hawk-owl; Brown/Barred Papuan Owl (*humeralis*)

Taxonomy. *Athene rufa* Gould, 1846, Arnhem Land, Northern Territory. Sometimes considered to form superspecies with *N. strenua*. Races require revision: *meesi* possibly only a pale morph of *queenslandica*; Aru population sometimes separated as *aruensis*, but apparently indistinguishable from *humeralis*; species has even been suggested as being monotypic. Four subspecies recognized.

Subspecies and Distribution.

N. r. humeralis (Bonaparte, 1850) - New Guinea, including Aru and Waigeo Is.
N. r. rufa (Gould, 1846) - NE Western Australia (Kimberleys) and N Northern Territory (Arnhem Land).
N. r. meesi Mason & Schodde, 1980 - coastal and subcoastal Cape York, S in Queensland to about R Endeavour and R Mitchell.
N. r. queenslandica Mathews, 1911 - coastal and subcoastal Queensland from R Endeavour S to lower R Burdekin and perhaps Rockhampton.

Descriptive notes. 40-52 cm; male c. 1200 g, female c. 980 g. A large hawk-owl with rather small head and long tail. Indistinct blackish facial disc; dark rufous-brown back, with narrow light brown bars; underparts white to buff, densely barred with rufous-brown; golden-yellow eyes; grey bill. Sexes similar, female smaller. Races differ in size and intensity of colour: *humeralis* smaller and browner; *queenslandica* large and dark, with paler underparts. **VOICE.** Low, slowly repeated "woo-hoo"; female higher-pitched than male.

Habitat. Mainly upland and lowland rainforest, well-wooded savanna, monsoon woodland,

gallery forest and forest edge, especially along waterways; less common in paperbark (*Melaleuca*) forest and mangrove. Lowlands and foothills to 2000 m in New Guinea; in Australia, up to at least 1200 m. Roosts by day singly or in pairs in thick-foliaged tree or tree hollow; often roosts clutching remains of large prey.

Food and Feeding. Main prey medium-sized mammals such as marsupials (*Antechinus*, *Isodon*, *Trichosurus*, *Pseudocheirus*, *Petaurus*), rodents (*Rattus*, *Conilurus*) and fruit bats (*Pteropus*), medium and large birds such as megapodes (Megapodiidae), including Australian Brush-turkeys (*Alectura lathami*), and large insects. Nocturnal, activity beginning about dusk. Takes insects from foliage; also takes prey from ground; often moves into more open areas adjoining forest to hunt; swoops, banks and glides through canopy to snatch arboreal mammals and roosting birds.

Breeding. Not well known. Lays c. Jun-Sept, tending to be earlier in warmer areas. Monogamous and territorial. Nest in debris of large hollow in large tree, often in trunk or main limb. Intensified calling prior to breeding. Usually 2 eggs, rarely 1; incubation by female, period c. 36-38 days; chick with whitish first and second down; fledging period c. 7-8 weeks.

Movements. Resident; perhaps some local movement in wet season.

Status and Conservation. Not globally threatened. CITES II. Subspecies *queenslandica* given as rare in Australian national listing and vulnerable in Queensland state listing, c. 1000 pairs estimated; *meesi* as rare in Queensland. Uncommon to rare and sparsely distributed in New Guinea; some pressure from traditional hunting. In Australia, adversely affected by forest clearance and, perhaps, by increasing numbers of hot fires late in dry season.

Bibliography. Andrew (1992), Beehler *et al.* (1986), Bell (1970), Bishop (1987), Blakers *et al.* (1984), Bravery (1970), Coates (1985), Estberg & Braithwaite (1985), Fleay (1979), Garnett (1993), Higgins (1999), Hollands (1991), Kanowski (1998), Lindsey (1992), Macdonald (1988), Mason & Schodde (1980), McAllan & Bruce (1989), Nielsen (1995), Olsen (1998), Olsen & Marples (1993), Pizzey & Doyle (1998), Rand & Gilliard (1967), Schmid (1993), Schodde & Mason (1981, 1997), Schodde & Tidemann (1986), Simpson & Day (1998), Strahan (1994), Trounson & Trounson (1987), Young & De Lai (1997).

161. Powerful Owl

Ninox strenua

French: Ninox puissante **German:** Riesenkauz **Spanish:** Ninox Robusto
Other common names: Eagle Owl(!), Great Scrub Owl

Taxonomy. *Athene ? strenua* Gould, 1838, New South Wales.

Sometimes considered to form superspecies with *N. rufa*. Monotypic.

Distribution. Coastal and subcoastal SE Queensland (S from R Dawson), E New South Wales and SE Victoria to extreme SE South Australia.

Descriptive notes. Male 52-60 cm, c. 1500 g; female 45-58 cm, c. 1250 g. Largest hawk-owl, with proportionately small, rather rounded head and long tail. Dark grey-brown facial disc and orange-yellow eyes; dark brown to dark grey-brown upperparts with off-white barring, and flecking on crown; off-white underparts with numerous bold dark chevrons; grey bill. Differs from *N. rufa* in larger size, lack of rufous tones, coarser barring; from *N. connivens* in much bigger size, spotted crown, plainer upperparts, no streaking on underparts. Sexes similar, female smaller. Immature with upperparts more strongly barred than adult. **VOICE.** Main call is far-carrying, repeated double hoot, "woo-hoo" or "ooo-hoo"; male deeper in pitch than female.

Habitat. Open forest, especially in both wet and dry, densely forested gullies near permanent water; also woodland and scrub; occasionally in forest adjoining city parkland, pine plantations and cultivated areas, and in remnants and regeneration surrounded by logged forest; from coast up to 1500 m. Perches by day singly, in pairs or in family groups under canopy, often clutching remains of partly eaten prey.

Food and Feeding. Large arboreal vertebrates, mainly phalangers (*Pseudocheirus peregrinus*, *Trichosurus vulpecula*, *Petaurus brevipes* and *Petauroides volans*), also flying foxes (Megachiroptera) and medium-sized

roosting birds. Nocturnal, becoming active just before dusk. Swoops to snatch prey from branches and canopy; less often, takes prey from ground in more open areas; occasionally hawks flying insects.

Breeding. Lays May-Jun, earlier in N than in S. Monogamous and territorial; home range 300-1450 ha in SE. Nest in large tree hole, usually in live tree, on decayed wood; rarely in dead snag or broken-off stump. 2 eggs; incubation period c. 35-38 days; female incubates, with male main hunter; young hatch in fine white down, white second down; fledging period c. 8 weeks; some remain dependent until start of next breeding season. Mean brood size at fledging c. 1-5.

Movements. Little known. Resident and largely sedentary; permanent territory occupied throughout year; young occasionally stray inland during dispersal.

Status and Conservation. VULNERABLE. CITES II. Listed as rare or vulnerable in Australian national listing and by 3 main states in which it occurs (Queensland, New South Wales and Victoria). However, probably more common and less habitat-specific than previously supposed. Threatened by clear-felling and loss of old-growth forest to forestry operations, but can tolerate selective or light logging and survives in fragmented forest.

Bibliography. Blakers *et al.* (1984), Brouwer & Garnett (1990), Chafer (1992a), Collar *et al.* (1994), Cooke *et al.* (1997), Davey (1993), Debus (1993a, 1995, 1997a, 1997d), Debus & Chafer (1994), Evans (1986), Eyre & Schulz (1996), Fleay (1944, 1979), Garnett (1993), Gibbons (1989), Higgins (1999), Hollands (1991), Hyem (1979), James, J.W. (1980), Kavanagh (1988, 1997), Kavanagh & Bamkin (1995), Kavanagh & Peake (1993a, 1993b), Kavanagh, Debus, Tweedie & Webster (1995), Lavazanian *et al.* (1994), Lindsey (1992), Macdonald (1988), McConnell (1997), McNabb (1987, 1994a, 1994b, 1996), O'Brien (1990), Olsen, J. 162. Barking Owl

Ninox connivens

French: Ninox aboyeuse **German:** Kläfferkauz **Spanish:** Ninox Ladrador
Other common names: Barking Hawk-owl, (Northern/Western) Winking Owl

Taxonomy. *Falco connivens* Latham, 1801, Sydney region, New South Wales.

Affinities uncertain. Some authors consider species monotypic, but up to seven races accepted by others; review needed. Proposed race *occidentalis* (NW & NC Australia) has been synonymized with *peninsularis*; *addenda* (SW Australia) synonymous with nominate. Some authors have placed birds of NC Queensland in race *enigma*, but type specimen, apparently lost, reported to be either juvenile of present species or aberrant, large individual of *N. boobook*. Four subspecies currently recognized.

Subspecies and Distribution.

N. c. rufostriata (G. R. Gray, 1860) - N Moluccas (Morotai, Halmahera, Bacan, Obi).
N. c. assimilis Salvadori & D'Albertis, 1875 - C & E New Guinea W to Merauke and R Sepik, including Manam I and Karkar I.
N. c. peninsularis Salvadori, 1876 - coastal and subcoastal NW, N & NE Australia S to R Endeavour in Queensland, and islands in SW Torres Strait.
N. c. connivens (Latham, 1801) - coastal and subcoastal SW Australia, southern gulfs, and E & SE Australia (S from foot of Cape York Peninsula).

Descriptive notes. 38-44 cm; male c. 700 g, female c. 600 g (*connivens*); male c. 500 g, female c. 440 g (*peninsularis*). Medium-sized hawk-owl. Indistinct facial disc and whitish eyebrows; head and upperparts dark brown to dark greyish-brown, with bold white spots on scapulars and wing-coverts; underparts creamy-buff to whitish with bold dark brown streaks; eyes yellow; bill black. Differs from *N. boobook* in larger size, proportionately smaller head, heavier markings above; from similar-sized *N. squamipila* in streaked (not barred) underparts; from smaller *N. scutulata* in paler head, patterned upperparts. Races

assimilis and *peninsularis* smaller, with chestnut-brown streaks below; *rufostriata* browner above. **VOICE.** Mainly a distinctive, repeated, gruff, low-pitched, dog-like "wuk-wuk" by male and higher-pitched "wok-wok" by female; less often a drawn-out strangled scream; pairs often duet.

Habitat. Lowland riparian forest, forest edge, woodland and savanna up to c. 1000 m in New Guinea; dry, open sclerophyll forest and woodland in Australia; often in riparian vegetation near swamps, lakes, streams and other wetlands. Roosts by day in foliage of canopy or mid-storey, or tree hollow, often in pairs or family groups.

Food and Feeding. Large insects; also vertebrates such as possums and gliders (Phalangeridae), rabbits (*Oryctolagus cuniculus*), rodents and small to medium-sized roosting birds; occasionally reptiles. In one study, insects, although numerically dominant, never contributed more than 5% by biomass. More crepuscular than most *Ninox*, also nocturnal. Active hunter of terrestrial, arboreal or

aerial prey, mostly among trees or along forest edges. Hawks flying insects and bats in air, and makes short sallies from perch.

Breeding. Not well known. Lays mainly Jul-Sept, slightly later in S than in N. Monogamous; territorial, pairs recorded nesting 6 km apart, intensified calling prior to breeding. Nest in large open hollow in tree trunk; less often in branch, open fork of tree, or on ground. Usually 2-3 eggs (1-4); incubation c. 36 days, by female; young hatch in creamy-white down, second down whitish; fledging period c. 5-6 weeks; young disperse from natal territory by late summer. In captivity, first breed at 1 year; later in wild.

Movements. Apparently resident, but poorly known.

Status and Conservation. Not globally threatened. CITES II. Widespread throughout range. Generally thinly scattered; quite common in New Guinea, but uncommon and local in Moluccas. In SE Australia evidence of decline in population, and concern because much habitat continues to be lost and degraded by clearing and overgrazing. Listed as vulnerable in New South Wales and Victoria.

Bibliography. 163. Sumba Boobook

Ninox rudolfi

French: Ninox de Sumba

German: Sumbakauz

Spanish: Ninox de Sumba

Other common names: Sumba Hawk-owl

Taxonomy. *Ninox rudolfi* A. B. Meyer, 1882, Sumba Island.

Sometimes considered to form superspecies with *N. boobook* and *N. novaeseelandiae*. Often treated as conspecific with *N. boobook*, which itself was formerly regarded as belonging to *N. novaeseelandiae*. Species name sometimes spelt, erroneously, *rudolfi*. Monotypic.

Distribution. Sumba I, in C Lesser Sundas.

Descriptive notes. c. 35-40 cm; female slightly larger than male. White eyebrows and chin, and yellow (or possibly brown) eyes; crown and upperparts brown, crown heavily spotted white, upperparts less so; wings and tail thinly barred; underparts whitish, strongly barred red-brown. Voice. Reported to be series of short, repeated, cough-like notes; suggests threat call of *N. boobook*, rather than usual 2-note boobook advertising call.

Habitat. Primary and tall secondary evergreen and deciduous forest, including monsoon forest, rainforest, remnant forest patches and forest edge; lowlands to c. 930 m.

Food and Feeding. Diet poorly known; probably mainly large insects. Similar in habits to *N. boobook*. Occurs singly, in pairs or loose (family?) groups of up to 4 birds.

Breeding. Apparently undescribed; 1 possible nest sighted, in cavity of huge tree.

Movements. Undescribed; probably resident.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species; present in Sumba EBA. Poorly known; once more common, now uncommon or rare. Found at only 5 localities during 1989 and 1992 surveys. Threatened by extensive clearing and repeated burning for grazing and agriculture; forest now covers less than 10% of island, and there is only 1 protected area.

Bibliography. Andrew (1992), Coates & Bishop (1997), Collar *et al.* (1994), Inskipp *et al.* (1996), Jones, Juhaeni *et al.* (1994), Jones, Linsley & Marsden (1995), Mayr (1944), Mees (1964), Pitches (1998a), Stattersfield *et al.* (1998), Sujatnika & Jepson (1995), Sujatnika *et al.* (1995), White & Bruce (1986).

164. Southern Boobook

Ninox boobook

French: Ninox de Australie

German: Boobookkauz

Spanish: Ninox Australiano

Other common names: Boobook (Owl), Streaked/Northern/Australian Boobook; Red/Dark Boobook (*lurida*)

Taxonomy. *Strix Boobook* Latham, 1801, Sydney area, New South Wales.

Sometimes considered to form superspecies with *N. rudolfi* and *N. novaeseelandiae*; various other proposed treatments, e.g. as member of species-group that includes *N. novaeseelandiae*, *N. squamipila*, *N. theomacha*, *N. meeki*, *N. variegata* and perhaps other boobooks in Australasian Region; more research needed. Has often been treated as conspecific with *N. novaeseelandiae*, but separated specifically by morphological and molecular differences; Tasmanian race *leucopsis* of latter has been placed with present species, which formerly also included *N. rudolfi* as race. No consensus on number of races, much in need of revision, especially non-Australian forms. Kangaroo I population has been described as separate race (*halmaturina*), but seems not constantly separable from nearby mainland population of nominate; also, *marmorata* of SW & SC Australia synonymous with *ocellata*. Ten subspecies tentatively recognized.

Subspecies and Distribution.

N. b. rotiensis Johnstone & Darnell, 1997 - Roti.

N. b. fusca (Vieillot, 1817) - Timor.

N. b. plesseni Stresemann, 1929 - Alor.

N. b. moue Mayr, 1943 - Romang, Leti and Moa.

N. b. cinnamomina Hartert, 1906 - Babar.

N. b. remigialis Stresemann, 1930 - Kai Is.

N. b. pusilla Mayr & Rand, 1935 - S New Guinea.

N. b. ocellata (Bonaparte, 1850) - Australia W of Great Dividing Range; rarely, islands in Torres Strait; also Sawu (W of Timor).

N. b. lurida De Vis, 1887 - NE Queensland between Cooktown and Paluma.

N. b. boobook (Latham, 1801) - coastal and subcoastal E Australia, S from S Queensland.

Descriptive notes. 25-36 cm (*pusilla* 25-28 cm, *boobook* 30-36 cm); male c. 250 g, female c. 315 g; clinal variation, smaller in warmer areas. Small, stocky and rather large-headed. Indistinct, darkish, dusky facial disc, white eyebrows; upperparts dark grey-brown or chocolate-brown with white spots; whitish below, variably spotted and streaked reddish-brown; eyes variable, yellow to hazel; feet grey or yellow. Differs from *N. novaeseelandiae* in being generally larger and paler, with less rounded wings; from *N. theomacha* in larger size and more patterned plumage. Sexes similar; female tends to have slightly more streaking/spotting on head and back than male. Juvenile tends to be more heavily streaked than adult on crown, nape and breast. Races differ in size and in intensity and extent of plumage colours and markings: all smaller than nominate; *lurida* darker chestnut-brown and lightly marked; *ocellata* paler, sandy-brown, with buff-streaked underparts; *fusca* grey-brown, heavily spotted below. Voice. Commonest call a repeated double hoot, "boo-book" or "bru-bruk".

Habitat. Wide variety, from forest, woodland, farmland, suburbs, to sparsely treed semi-deserts. In wet tropics, primary and tall secondary hill monsoon forest and woodland; generally in lowlands and foothills, but up to 2300 m on Timor. Race *lurida* found only in montane rainforest. Roosts by day in thick foliage, rarely on ground among grass or in caves or tree holes, singly, in pairs or in family groups.

Food and Feeding. Mainly insects; also, particularly when breeding, small to medium-sized vertebrates including bats, rodents, birds, lizards and frogs. Mainly nocturnal, also partly crepuscular. Hunts in forest, forest edge or out into open areas, hawking aerial insects, snatching prey from canopy and mid-storey, and pouncing on prey on ground; often hunts by moving from perch to perch; catches surplus prey in notches or crevices.

Breeding. Lays late Aug-Nov, slightly later in S than in N. Monogamous; territorial, intensified calling prior to breeding. Nest in tree hole in trunk, spout or chimney, on decayed wood; main home range estimated at c. 8 ha, larger range c. 37 ha, but dependent on habitat. Usually 3 eggs, rarely 4-5, laid every second day; incubation c. 30 days, by female; chick with creamy-whitish first and second down, hazel to yellow eyes at fledging; typically, 2-3 chicks fledge at c. 5 weeks; family stays together another c. 3 months, juveniles disperse late summer to autumn. In captivity, breeds at 1 year old; in wild, age of first breeding probably at least 2 years for females, 3 for males.

Movements. Not well known; largely resident, some winter dispersal. Southernmost populations possibly partially migratory, move N and to lower altitudes in winter.

Status and Conservation. Not globally threatened. CITES II. Widely distributed and common through forest of New Guinea; moderately common on Timor; in Australia, widespread and generally common. Quite tolerant of habitat disturbance, but loss of tree hollows through clearing, degradation and lack of regeneration may cause problems in future. Some evidence of DDT-induced eggshell-thinning, but unlikely to be widespread; some evidence of secondary poisoning in pest-control programmes for rats (*Rattus*) in Australia, but local in effect.

Bibliography. Andrew (1992), Baker-Gabb (1984), Baldwin (1975), Beehler *et al.* (1986), Blakers *et al.* (1984), Bone (1995), Bravery (1970), Campbell & Rose (1996), Chatto (1989), Christidis & Boles (1994), Clancy (1977), Coates (1985), Coates & Bishop (1997), Debus (1996a, 1996b, 1997a, 1997d), Fleay (1925, 1926, 1979), Ford (1987), Higgins (1999), Hollands (1991), Hyem (1979), Inskipp *et al.* (1996), Kavanagh & Bamkin (1995), Kavanagh & Peake (1993a, 1993b), Kavanagh, Debus, Tweedie & Webster (1995), Kutt (1994), Lindsey (1992), Macdonald (1988), Mayr (1944), Mayr & Rand (1937), McNabb (1994a), Mees (1964), O'Brien (1990), Olsen (1997, 1998), Olsen & Bartos (1997), Olsen & Marples (1993), Olsen & Moon (1990), Olsen *et al.* (1993), Pizzey & Doyle (1998), Rand & Gilliard (1967), Rose (1996b), Sayers (1976), Schodde & Mason (1981, 1997), Schodde & Tidemann (1986), Simpson & Day (1998), Singor (1996), Strahan (1994), Trounson & Trounson (1987), White & Bruce (1986).

165. Morepork

Ninox novaeseelandiae

French: Ninox boubook

German: Kuckuckskauz

Spanish: Ninox Maori

Other common names: Ruru; Spotted Boobook (*leucopsis*); Norfolk (Island) Boobook (*undulata*); New Zealand Boobook (*novaeseelandiae*)

Taxonomy. *Strix novae Seelandiae* J. F. Gmelin, 1788, Queen Charlotte Sound, South Island, New Zealand.

Sometimes considered to form superspecies with *N. rudolfi* and *N. boobook*; various other proposed treatments, e.g. as member of species-group that includes *N. boobook*, *N. squamipila*, *N. theomacha*, *N. meeki*, *N. variegata* and perhaps other boobooks in Australasian Region; more research needed. Often considered to include *N. boobook* as race, but latter separated specifically by morphological and molecular differences. Race *leucopsis* formerly placed with *N. boobook*, but recently included with present species on basis of molecular affinities; possibly specifically distinct from both. Birds of North I formerly separated as race *venatica*, but differences minimal and possibly not consistent. Race *albaria* from Lord Howe I extinct. Three subspecies recognized.

Subspecies and Distribution.

N. n. leucopsis (Gould, 1838) - Tasmania and Bass Strait islands.

N. n. undulata (Latham, 1801) - Norfolk I.

N. n. novaeseelandiae (J. F. Gmelin, 1788) - New Zealand, including most offshore islands.

Descriptive notes. c. 29 cm; male c. 156 g, female c. 170 g. Very small, stocky, with relatively round wings and long tail. Indistinct greyish-white facial disc, and white or cinnamon eyebrows; upperparts chocolate-brown to deep rufous with white flecks; buff to umber flecks and streaks ventrally; golden-yellow eyes; feathered tarsi. Differs from *N. boobook* in being generally smaller and darker, with more rounded wings. Sexes similar, female slightly more streaked/spotted on head and back. Juvenile tends to be more heavily streaked than adult on crown, nape and breast. Races differ in size, and in intensity and extent of plumage colours and markings: *leucopsis* more neatly spotted white; *undulata* more barred above, more rufous below. Voice. Commonest call a repeated double hoot, "boo-book".

tent of plumage colours and markings: *leucopsis* more neatly spotted white; *undulata* more barred above, more rufous below. Voice. Commonest call a repeated double hoot, "boo-book".

Habitat. Forest, farmland and pine plantations at lower altitudes, extending up to tree-line. Roosts under dense canopy or in tree hole.

Food and Feeding. Mainly insects; also spiders, and small to medium-sized vertebrates such as birds, rodents, bats and lizards. Typically begins hunting in early hours of dusk, returning before dawn to roost. Hunts mainly by perch-hopping, snatching prey from canopy, from ground and around street lights; hawks flying insects in air.

Breeding. Lays late Sept-Nov, later in S than in N. Monogamous; territorial, intensified calling prior to breeding. Nest in tree hollow, less often in epiphytes, rarely in cave or river-bank cavity; home range estimated at 4-8 ha in New Zealand forest. Usually 2 eggs, rarely 3, laid every second day; incubation c. 30 days, by female; chick with greyish-white first down, sooty-grey second down and golden-yellow eyes; typically, 2 chicks fledge at c. 5 weeks; family stays together another c. 3 months. In captivity, can breed at 1 year old; in wild, age of first breeding probably at least 2 years for females, 3 for males.

Movements. Mainly resident; movements poorly understood. Young may disperse in winter, reaching islands where not normally seen; a few from Tasmania winter in mainland Australia.

Status and Conservation. Not globally threatened. CITES II. Widely distributed and common through forest of New Zealand's main islands and large offshore islands; also in farmland, small woods, parks and treed suburbs, and some pine plantations, but displaced by introduced *Athene noctua* in more open parts of South Island; some evidence of secondary poisoning in pest-control programmes for possums (Phalangeridae), but local in effect. Race *undulata* endangered on Norfolk I mainly through clearing and selective logging, only 1 female individual remaining in 1985-86; now survives as hybrid population *undulata* × *novaezeelandiae*, using nestboxes. Race *albata* extinct on Lord Howe I since 1950's, this due to clearing of forest and introduced species. Race *leucopsis* widespread and common in Tasmania. Race *undulata* CITES I.

Bibliography. Anderson (1992), Brown *et al.* (1998), Chambers (1989), Christidis & Boles (1994), Clark, J.M. (1992), Clark, R.J. & Mikko (1989), Cunningham (1948), Dawson *et al.* (1978), Disney & Smithers (1972), Double & Olsen (1997), Garnett (1993), Falla *et al.* (1981), Fielding (1979), Fitzgerald *et al.* (1989), Garnett (1993), Green *et al.* (1986), Hay (1986), Heather & Robertson (1997), Hermes (1985), Hicks (1991), Hicks *et al.* (1990), Higgins (1999), Hindwood (1940), Hogg & Skegg (1961), Howell (1976), Hutton (1991), Imboden (1975), Inskipp *et al.* (1996), King (1978/79), Knox & Walters (1994), Lindsay & Ordish (1964), McCann (1959), Moon (1967, 1992), Norman, Olsen & Christidis (1998), O'Donnell (1980), Olsen (1989, 1996, 1998), Olsen & Hicks (1994), Olsen & Moon (1990), Olsen *et al.* (1989), Robertson (1985), Rooke (1986), Scarlett (1961), Schodde & Mason (1981), Schodde *et al.* (1983), Sibson (1989), Smithers & Disney (1969), Soper (1976), St. Giron *et al.* (1986), St. Paul & McKenzie (1977), Stephenson & Minot (1998), Turner *et al.* (1968), Williams (1975).

166. Brown Hawk-owl

Ninox scutulata

French: Ninox hirsute **German:** Falkenkauz **Spanish:** Ninox Pardo
Other common names: Brown Boobook, Oriental/Hume's/Philippine/Burmese Brown Hawk-owl, Indonesian Punggok

Taxonomy. *Strix scutulata* Raffles, 1822, Sumatra.

Relationships uncertain. Normally, 9-12 races recognized; *obscura* perhaps specifically distinct, but many others doubtfully separable subspecifically; taxonomy in need of revision. Name *scutulata* formerly applied to populations from E China, Korea, Japan and Taiwan (currently *japonica*) on erroneous supposition that type specimen, from Sumatra, was migrant form; populations now recognized as nominate form were placed in race *malaccensis*. Eleven subspecies recognized.

Subspecies and Distribution.

- N. s. ussuriensis* Buturlin, 1910 - SE Siberia, SE Manchuria and N Korea.
- N. s. japonica* (Temminck & Schlegel, 1844) - E China, C & S Korea, Japan and Taiwan.
- N. s. lugubris* (Tickell, 1833) - N & C India to W Assam.
- N. s. hirsuta* (Temminck, 1824) - S India and Sri Lanka.
- N. s. obscura* Hume, 1873 - Andaman and Nicobar Is.
- N. s. burmanica* Hume, 1876 - E Assam to S China, S to N Malay Peninsula, Thailand and Indochina.
- N. s. palawanensis* Ripley & Rabor, 1962 - Palawan.
- N. s. randi* Deignan, 1951 - Philippines (Luzon, Marinduque, Mindoro, Negros, Cebu, Siquijor, Mindanao, Basilan).
- N. s. scutulata* (Raffles, 1822) - S Malay Peninsula, Riau Archipelago, Sumatra and Bangka.
- N. s. javanensis* Stresemann, 1928 - W Java.
- N. s. borneensis* (Bonaparte, 1850) - Borneo and N Natuna Is.

Descriptive notes. 27-33 cm; 172-227 g. Medium-sized hawk-like owl with long wings and tail. Face almost wholly dark; indistinct dark facial disc, and small white patch between golden-yellow eyes; compact plumage, uniformly dark brown dorsally, tail broadly barred pale; buffish-white below, boldly streaked reddish-brown; grey bill with darker tip; feathered tarsi. Distinguished from most congeners by lack of white spots above; from *N. affinis* by brown head. Sexes similar in plumage, female larger. Geographical variation in size, colour of head and amount of white ventrally; *obscura* distinct, wholly dark brown all over. **VOICE.**

Most commonly a repeated, mellow, rising falsetto, disyllabic hoot, "pung-ok" or "oo-uk"; occasionally duets.

Habitat. Wide variety of deciduous, evergreen and coniferous forest types, from scrub to mangrove, rainforest and river thickets; also cultivated land, including plantations, parks and suburbs; in lowlands and hills, up to 1200-1500 m, but dependent on area. Roosts by day singly or in pairs under thick canopy or among creepers.

Food and Feeding. Mainly flying insects, such as dragonflies (Odonata) and moths (Lepidoptera) caught in air; also takes small crabs (Decapoda), and wide variety of vertebrates including lizards, amphibians, small birds and mammals, including bats. Crepuscular and nocturnal; begins hunting before dusk, at forest edge or in cultivated areas.

Breeding. Lays Mar-Apr in Sumatra and Sri Lanka, Mar-Jun in Assam, Apr in China, late May-Jul in Japan, c. Jul (and earlier?) in India. Monogamous. Nest in tree hole. Usual clutch 2-5 eggs, but varies regionally; incubation said to take 25 days, but this probably too short, and fledging a further 28 days.

Movements. N races migrate as far S as Malay Peninsula, Sumatra, Java, Borneo, Philippines, Sulawesi, Moluccas and Lesser Sundas, to overlap with resident tropical S populations; record of beach-washed specimen, probably *japonica*, on Ashmore Reef, NW Australia. Some Japanese birds winter in E China.

Status and Conservation. Not globally threatened. CITES II. Very common in Japan in summer; common passage migrant to Korea in Apr-May and Sept, with a few summer visitors to C & S provinces; rare in SE Siberia. Uncommon in Borneo and Sumatra; rare in Java; generally uncommon throughout Moluccas and Lesser Sundas, but slightly more common in N Sulawesi region, including Talaud Is and Sangihe. In Indian Subcontinent, locally fairly common in N; common in SE Asia.

Bibliography. Ali (1996), Ali & Ripley (1981), Brazil (1991), Brazil & Yamamoto (1989a), Caldwell & Caldwell (1931), Coates & Bishop (1997), Deignan (1945), Dickinson (1975), Dickinson *et al.* (1991), Étchéopar & Hue (1978), Flint *et al.* (1984), Gore & Pyong-Oh (1971), Grimmett *et al.* (1998), Hellebrekers & Hoogerwerf (1967), Higgins (1999), Inskipp & Inskipp (1991), Kawamoto (1991), Knystautas (1993), Lekagul & Round (1991), MacKinnon & Philipps (1993), Madoc (1976), van Marle & Voous (1988), McCann (1933), Medway & Wells (1976), Nakamura (1975), Neelakantan (1979), Phillips (1978), Riley (1938), Ripley (1982), Roberts (1991), Rozendaal & Dekker (1989), Sankaran (1998), Schodde & Van Tets (1981), Smythies (1981, 1986), Stepanyan (1990, 1995), Taniguchi (1983), Tikader (1984), Voous (1988), Wells (1999), White & Bruce (1986), Zhao Zhengjie (1995).

167. Andaman Hawk-owl

Ninox affinis

French: Ninox des Andaman **German:** Andamanenkauz **Spanish:** Ninox de Andamán
Other common names: Nicobar Hawk-owl, Andaman/Nicobar Boobook

Taxonomy. *Ninox affinis* Beavan, 1867, Aberdeen Point, Port Blair, Andaman Islands.

Affinities uncertain. Populations sometimes separated subspecifically, as *affinis* in Andamans and *isolata* in Nicobars, with third form (*rexpimenta*) on Great Nicobar occasionally separated from latter; further study, including on vocalizations, required. Monotypic.

Distribution. Andaman Is (South Andaman) and Nicobar Is (Great Nicobar, Camorta, Trinkat, Car Nicobar).

Descriptive notes. 25-28 cm. Head grey with darker eyebrows, faintly defined facial disc, white rictal bristles surrounding yellow bill; dark brown above, tail broadly barred pale; white below with bright rufous spotting or streaking, denser on upper breast; eyes yellow. Distinguished from sympatric dark race *obscura* of *N. scutulata* by pale and streaked underparts and yellow bill. Sexes similar in plumage, female slightly larger. Birds from Nicobars larger and browner. **VOICE.** Single loud "eraw" recorded in Andamans.

Habitat. Forest, rubber plantations and settlements; open forest, mangroves.

Food and Feeding. Poorly known; observed hawking moths; also takes beetles and grasshoppers. **Breeding.** Largely unknown; young bird found in May.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Andaman Islands EBA and Nicobar Islands EBA. Currently considered Near-threatened. Few records, but species reported as frequently sighted Jan-Mar 1996 at S tip of Great Nicobar. Andaman and Nicobar Is are least spoilt islands remaining in Indian Ocean; thus, species' immediate future seems secure, although long-term survival uncertain.

Bibliography. Abdulali (1967, 1978), Ali & Ripley (1981), Butler (1899), Diamond, A.W. (1985), Grimmett *et al.* (1998), Ripley (1982), Sankaran (1998), Stattersfield *et al.* (1998), Tikader (1984).

168. White-browed Hawk-owl

Ninox supercilii

French: Ninox à sourcils blancs **German:** Madagaskarkauz **Spanish:** Ninox Malgache
Other common names: White-browed Owl/Boobook, Madagascar Hawk-owl

Taxonomy. *Strix supercilii* Vieillot, 1817, Madagascar.

Affinities uncertain; variously considered closely related to *N. scutulata* or rather separate from entire *Ninox* genus; further research needed. Monotypic.

Distribution. NE, SW & S Madagascar.

Descriptive notes. 23-28 cm. Round, brown head with inconspicuous tan-grey facial disc, distinct white eyebrows above brown eyes; white speckles on crown; upperparts uniform brown with few white speckles, mostly on wing-coverts; underparts white with uniform brown bars throughout; yellow bill and feet. **VOICE.** Extremely vocal at night, giving 2 muffled disyllabic hoots, "ho-o-o. hoo", followed by 15-20 discordant calls, "kiang kiang...", that rise in pitch and volume.

Habitat. Open terrain with few trees, semi-arid thorn scrub, wooded savanna, deciduous dry forest, evergreen rainforest, rocky ravines; from

sea-level to 800 m.

Food and Feeding. Mainly insects; also reptiles, small birds and mammals. Strictly nocturnal. Hunts by surveying area overlooking open space from perch, and dropping to catch prey; probably relies on sight for hunting.

Breeding. Little known. Lays during Oct-Dec; nest a shallow depression on ground, or in open tree cavity; 3-5 eggs.

Movements. Resident. Rare wanderers to N Madagascar are probably dispersing immatures.

Status and Conservation. Not globally threatened. CITES II. Fairly common in W & S in dry forest, e.g. at Kirindi, Zombitse-Vohibasia National Park and Berenty Private Reserve; less common in Ankarana in N. Depends mainly on forest lands; may be at risk, since much natural habitat has been destroyed by logging. However, numbers appear to be moderately high W of central plateau and Bara region. Few reports from E side of island, but recently recorded on nest in Andranobe, Masoala Peninsula National Park, in NE.

169. Philippine Hawk-owl

Ninox philippensis

French: Ninox des Philippines **German:** Philippinenkauz **Spanish:** Ninox Filipino
Other common names: Philippine Boobook (Owl); Mindoro Hawk-owl (*mindorensis*); Spotted Hawk-owl (*spilonota*); Mindanao/Tweeddale's Hawk-owl (*spilocephala*)

Taxonomy. *Ninox philippensis* Bonaparte, 1855, Philippines. Relationships unclear; possibly close to *N. ochracea*. Subspecific divisions uncertain and confused, and races sometimes combined into three groups based on apparent relationships: *philippensis* with *proxima* and *centralis*; *spilocephala* with *reyi*; and *spilonota* with *mindorensis*; these groups sometimes treated as three separate species. Other authors merge races as indicated by those groupings, treating only nominate, *spilocephala* and *spilonota* as valid, or with *mindorensis* as additional race; the latter, moreover, has recently been found to be quite distinct in plumage and voice, and may be a full species. Another recent proposal groups *mindorensis* and *spilonota* with *reyi*, despite the fact that latter usually allied with *spilocephala*; this new grouping of bar-bellied forms, inhabiting a considerable number of smaller islands, would include at least two unnamed races, and may constitute a separate, polytypic species, for which the name *reyi* has priority. Further research under way. Proposed race *everetti* of Siasi synonymous with *reyi*. Seven subspecies recognized.

Subspecies and Distribution.

N. p. philippensis Bonaparte, 1855 - Luzon, Polillo, Marinduque, Catanduanes, Samar, Leyte, Buad, and perhaps Biliran.
N. p. mindorensis Ogilvie-Grant, 1896 - Mindoro.
N. p. spilonota Bourns & Worcester, 1894 - Sibuyan, Tablas, Cebu and Camiguin Sur.
N. p. proxima Mayr, 1945 - Masbate, Ticao.
N. p. centralis Mayr, 1945 - Panay, Guimaras, Negros, Bohol, Siquijor.
N. p. spilocephala Tweeddale, 1879 - Basilan, Mindanao, Dinagat, Siargao.
N. p. reyi Oustalet, 1880 - Sulu Archipelago.

Descriptive notes. 15-20 cm; c. 125 g. Very small hawk-owl, with indistinct brown facial disc, greyish rictal bristles and whitish eyebrows; head and upper back dark rufous-brown, with white spotting on scapulars and upper-wing-coverts; flight-feathers heavily spotted; white throat collar; buff-white underparts streaked rufous-brown; deep orange-yellow eyes; creamy yellow-grey bill. Distinguished from *N. scutulata* by extensive white covert spots and more rufous, less chocolate-brown colour of upperparts. Sexes similar in plumage, female slightly larger. Juvenile less spotted. Races differ in coloration and markings:

spilocephala paler and less spotted above (except crown), chest washed rufous; *spilonota* barred below, with buff belly; *mindorensis* barred below, with well-marked white eyebrows. VOICE. Little known; loud, repeated, single-note "whooh".

Habitat. Secondary growth and primary forest, including remnants, gallery forest and edge, from lowlands to high altitudes. Roosts by day in darker parts of forest.

Food and Feeding. Insects and rodents.

Breeding. Nestlings in white down collected in Mar and May; nest in tree hole. No further information available.

Movements. Unknown; probably resident.

Status and Conservation. Not globally threatened. CITES II. Severe deforestation has occurred throughout Philippines, but species tolerates some degree of habitat alteration and is still locally common. Occurs in several National Parks, such as Quezon (Luzon), Mount Canlaon (Negros), Rajah Sikatuna (Bohol) and Mount Katanglad (Mindanao). Race *mindorensis* common in Siburan Forest (50 km²), the largest remnant of lowland forest in Mindoro, protected by the presence of a penal colony; more than 90% of the island, though, has been deforested, and the process has undoubtedly continued in the last few years. Races *spilonota* and *reyi*, inhabiting small islands, highly threatened by habitat destruction, with local extinctions very likely, e.g. on Cebu and Tablas.

Bibliography. Alcalá & Alviola (1970), Brooks, Dutson, Gabutero & Timmins (1995), Brooks, Dutson, King & Magsalay (1996), Collar & Rasmussen (1998), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), Gilliard (1950a), Gogorza y González (1887), Gonzales (1983), Gonzales & Rees (1988), Goodman & Gonzales (1990), Hachisuka (1941), Inskipp *et al.* (1996), Manuel (1957), McGregor (1909-1910), Oliver & Wirth (1996), Parkes (1965), duPont (1971), duPont & Rabor (1973a, 1973b), Rabor (1938a, 1977), Rand & Rabor (1960), Robson & Davidson (1996).

170. Ochre-bellied Hawk-owl

Ninox ochracea

French: Ninox ocrée **German:** Ockerbauchkauz **Spanish:** Ninox Ocráceo
Other common names: Ochre-bellied Boobook

Taxonomy. *Noctua ochracea* Schlegel, 1866, Negri-lama, Gulf of Tomini, Sulawesi. Affinities uncertain. Closest relative probably *N. philippensis*; considered by some authors to be close to *N. punctulata*, but this apparently far from the case. Sometimes referred to as *N. perversa*, as name *ochracea* erroneously thought to be preoccupied. Monotypic.

Distribution. Sulawesi and Butung.

Descriptive notes. c. 29 cm. Brown upperparts and tawny underparts, with bold white scapular spots; white throat and eyebrows; yellow eyes. Differs from *N. punctulata* in paler coloration, without dark mask; from *N. scutulata* in spotted scapulars and pale throat. Sexes similar, female slightly larger. Voice. Commonest call is series of hoarse, somewhat guttural, single "kau" notes, developing into series of 2-noted calls, "wu kau", second note more drawn out than first.

Habitat. Primary and tall secondary lowland forest and riverine forest, to c. 1000 m. Roosts by day, singly or in pairs, in dense vegetation such as rattan palm.

Food and Feeding. Food apparently unrecorded. Hunts from perches in mid-storey or lower canopy, particularly where overlooking road or forest opening.

Breeding. No information.

Movements. No information. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Sulawesi EBA. Little known and status uncertain; generally uncommon but locally moderately common, e.g. in Lore Lindu National Park; also occurs at Dumoga-Bone National Park and Tangkoko Nature Reserve. Fairly wide-

spread, but apparently not recorded from S Sulawesi.

Bibliography. Andrew (1992), Catterall (1997), Clark & Mikkola (1989), Coates & Bishop (1997), Holmes & Philipps (1996), Mees (1964), Riley (1924), Rozendaal & Dekker (1989), Stattersfield *et al.* (1998), Stressemann (1938a), Sujatnika *et al.* (1995), Watling (1983), White & Bruce (1986).

171. Moluccan Hawk-owl

Ninox squamipila

French: Ninox des Moluques **German:** Molokkenkauz **Spanish:** Ninox Moluqueño
Other common names: Moluccan Boobook

Taxonomy. *Athene squamipila* Bonaparte, 1850, Ceram.

Relationships unclear. Proposed treatment as member of species-group that includes *N. boobook*, *N. novaezealandiae*, *N. theomacha*, *N. meeki*, *N. variegata* and perhaps other boobooks in Australasian Region, or possibly with just last 3 of above-named species; more research needed. Formerly included *N. natalis* as race, but latter now afforded full species status based on plumage details and molecular evidence. Races are morphologically quite distinct, and there is some preliminary evidence that vocalizations also differ; more than one species may be involved. Four subspecies recognized.

Subspecies and Distribution.

N. s. hypogramma (G. R. Gray, 1860) - Halmahera, Ternate and Bacan group.
N. s. hantu (Wallace, 1863) - Buru.
N. s. squamipila (Bonaparte, 1850) - Seram.
N. s. forbesi P. L. Slater, 1883 - Tanimbar Is.

Descriptive notes. 25-39 cm. Plain brown head and mantle, with some spotting or barring on back, few spots on wing-coverts; flight-feathers and tail barred; chest rufous, rest of underparts whitish, all vermiculated dark brown; eyes deep yellow. Differs from *N. scutulata* and larger *N. connivens* in barred rather than streaked breast. Sexes similar, female slightly larger. Races vary in size and plumage: *hypogramma* very dark, with grey crown and rusty ventral barring; *hantu* rufous below, indistinctly barred; *forbesi* bright rusty-brown. VOICE. Commonest call a 2-note, repeated hoot, "wu-wu" or "ook-ook"; perhaps some variation between islands.

Habitat. Primary and tall secondary forest; selectively logged forest and forest edge in lowlands and hills; roosts in dense vegetation by day. Occurs from sea-level to 1200 m on Halmahera and Bacan, to 1400 m on Seram and 1750 m on Buru.

Food and Feeding. Mainly insects, but diet poorly known. Hunts from perches in mid-storey and lower canopy, often exposed branches or stumps; occurs singly or in pairs.

Breeding. Apparently undescribed.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Banda Sea Islands EBA, Buru EBA, Seram EBA and Northern Maluku EBA. Locally moderately common on Halmahera, Seram and Tanimbar Is. Nominant race occurs at Manusela National Park, Seram.

Bibliography. Andrew (1992), Bowler & Taylor (1989), Coates & Bishop (1997), Inskipp *et al.* (1996), Isherwood, Edwards *et al.* (1998), Isherwood, Willis *et al.* (1997), Norman, Christidis *et al.* (1998), Schodde & Mason (1997), Stattersfield *et al.* (1998), Sujatnika *et al.* (1995), White & Bruce (1986).

172. Christmas Hawk-owl

Ninox natalis

French: Ninox de Christmas **German:** Weihnachtskauz **Spanish:** Ninox de la Christmas
Other common names: Christmas Boobook

Taxonomy. *Ninox natalis* Lister, 1889, Christmas Island.

Formerly considered conspecific with *N. squamipila*, but separable on morphological and plumage details, molecular differences and perhaps voice. Monotypic.

Distribution. Christmas I (Indian Ocean).

Descriptive notes. 26-29 cm; 130-190 g. Dark chestnut facial mask, whitish brows, lores and throat, and golden-yellow eyes; upperparts rich rufous-brown with fine white spots on nape and wing-coverts and fine white bars on scapulars; underparts buff-white, densely barred rufous-brown; feet orange-yellow. Sexes similar in plumage, female slightly larger. VOICE. Typical call a repeated, double-noted hoot with somewhat clucking quality, "klu-gook".

Habitat. Dense rainforest, both tall evergreen and deciduous, on plateau and coastal terraces; less often in secondary forest. Roosts singly, in pairs or in family groups under dense foliage; tame and approachable.

Food and Feeding. Mainly large insects (especially Orthoptera, Lepidoptera and Coleoptera); also spiders. Occasionally small vertebrates such as geckos (Gekkonidae); birds, e.g. Christmas White-eye (*Zosterops natalis*); and introduced black rats (*Rattus rattus*). Nocturnal and crepuscular. Hunts into cleared areas, including those around roads and human settlements, hawking insects around lights; moves from perch to perch through forest in search of prey; takes prey from ground or canopy.

Breeding. Little known. Apparently extended breeding season, but possibly lays mainly c.

Jun-Jul; some observations indicate season Dec-Apr. Monogamous; territorial, intensified calling prior to breeding, beginning Apr. Nest in tree hole; defended territory estimated at c. 18 ha, maintained year-round. Clutch probably usually 2 eggs; incubation and length of nestling period unknown, probably similar to those of *N. boobook* and *N. novaeseelandiae*; fledglings dependent for 2-5 months or more.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES I. Widespread but confined to small, isolated Christmas I, where the only strigid; population estimated at c. 560 pairs in 1997. Listed as vulnerable in Australian national list. Probably declined by 25% since settlement and clearance of a quarter of forest during phosphate mining; much of island now protected in National Park, and mining has ceased.

Bibliography. Chasen (1933), Clark & Mikkola (1989), Garnett (1992, 1993), Gibson-Hill (1947), Gray (1981), Higgins (1999), Hill (1995, 1997), Hill & Lill (1998a, 1998b, 1998c), Inskipp *et al.* (1996), Kent & Boles (1984), King (1978/79), Norman, Christidis *et al.* (1998), Olsen (1998), Olsen & Stokes (1989), Phillips *et al.* (1991), Stokes (1988), Strahan (1994), Van Tets (1976).

173. Jungle Hawk-owl

Ninox theomacha

French: Ninox brune **German:** Einfarbkauz **Spanish:** Nínox Papú
Other common names: Sooty-backed/Chestnut Hawk-owl, Papuan (!)Jungle Boobook (Owl), Brown Owl(!)

Taxonomy. *Spiloglaux theomacha* Bonaparte, 1855, Triton Bay, New Guinea.

Relationships uncertain. Proposed treatments as member of species-group that includes *N. boobook*, *N. novaeseelandiae*, *N. squamipila*, *N. meeki*, *N. variegata* and perhaps other boobooks in Australasian Region; more research needed. Four subspecies recognized.

Subspecies and Distribution.

N. t. hoedtii (Schlegel, 1871) - Waigeo and Misool Is.

N. t. theomacha (Bonaparte, 1855) - New Guinea.

N. t. goldii Gurney, 1883 - D'Entrecasteaux Archipelago (Goodenough, Fergusson, Normanby).

N. t. rosselliana Tristram, 1889 - Louisiade Archipelago (Tagula, Rossel).

Descriptive notes. 20-28 cm. Small hawk-owl, relatively plain above and below. Facial disc uniformly black-brown, paler eyebrows, indistinct pale rictal bristles; sooty chocolate-brown above, unmarked or with few spots on scapulars; rich chestnut-brown below; yellow eyes; grey bill. Differs from *N. jacquinoti* in lack of white throat, dark and unbarred underparts. Sexes similar, female slightly larger. Juvenile dull brown. Races differ in size and colour: *hoedtii* duller than nominate, with browner head; *goldii* larger, belly with much white; *rosselliana* with even more white below. **VOICE.** Disyllabic "boo-boo", the two

notes identical, slightly descending in pitch, repeated every 3-4 seconds, continuing throughout most of night.

Habitat. Lowland forest, forest edge, gardens and tree groves in open country, up to c. 2500 m. Roosts under dense canopy by day.

Food and Feeding. Mainly large insects. Hunts using sallies from perch; hawks insects on wing; solitary or in pairs.

Breeding. Lays Aug; fledglings seen in Oct; eggs found in Dec in C New Guinea. Monogamous; territorial, intensified calling prior to breeding. Nest in tree hollow; usually 2 eggs.

Movements. Undescribed, probably resident.

Status and Conservation. Not globally threatened. CITES II. Widely distributed and common; occupies variety of habitats; highly adaptable.

Bibliography. Andrew (1992), Beehler (1978), Beehler *et al.* (1986), Clapp (1987), Coates (1985), Coles (1995), Diamond (1972), Gregory (1995a, 1995b), Mackay (1991), Majnep & Bulmer (1977), Mayr & Rand (1937), Mees (1965), Murray (1988), Peckover & Filewood (1976), Rand & Gilliard (1967), Simpson (1994).

174. Manus Hawk-owl

Ninox meeki

French: Ninox de l'Amirauté **German:** Manuskauz **Spanish:** Nínox de la Manus
Other common names: Manus Boobook, Admiralty (Islands) Hawk-owl

Taxonomy. *Ninox meeki* Rothschild and Hartert, 1914, Manus, Admiralty Islands.

Affinities unclear. Proposed treatments as member of species-group that includes *N. boobook*, *N. novaeseelandiae*, *N. squamipila*, *N. theomacha*, *N. variegata* and perhaps other boobooks in Australasian Region; more research needed. Monotypic.

Distribution. Manus I (Admiralty Is).

Descriptive notes. 23-31 cm. A small hawk-owl. Facial disc uniform brown, with white rictal bristles; crown and back rufous-brown, sometimes with indistinct paler mottling; flight-feathers and tail barred light rufous and brown; throat whitish or pale tawny; underparts whitish-buff with long rusty-brown streaks, densest on breast; eyes yellow; bill pale grey; feet creamy yellow.

Sexes similar, female slightly larger. Juvenile with heavier white barring above, narrower streaks below. **VOICE.** Not described.

Habitat. Forest and degraded forest. Also riparian cultivation and areas with trees around villages.

Food and Feeding. No information.

Breeding. No information.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Admiralty Islands EBA. Extremely poorly known species, with no data on population, ecology or biology; research

required. The fact that most of Manus is covered by forest (80% of vegetation being primary forest in 1987), and that this owl has been recorded in degraded habitats, suggests that, despite the tiny range, species is not currently at risk.

Bibliography. Buckingham *et al.* (1995), Coates (1985), Eastwood (1995), Gregory (1995d), Stattersfield *et al.* (1998).

175. Speckled Hawk-owl

Ninox punctulata

French: Ninox pointillée **German:** Pünktchenkauz **Spanish:** Nínox Punteado
Other common names: Speckled Boobook

Taxonomy. *Noctua punctulata* Quoy and Gaimard, 1830, Sulawesi.

Affinities uncertain; considered by some authors to be close to *N. ochracea*, but this apparently far from the case. Monotypic.

Distribution. Sulawesi, including Kabaena, Muna and Butung Is.

Descriptive notes. c. 27 cm; one male 151 g. Blackish facial disc, whitish eyebrows and throat; upperparts dark brown, densely dotted white; underparts with red-brown upper breast spotted buff, rest of underparts whitish-buff and faintly barred; yellow eyes and light creamy-yellow bill. Differs from *N. ochracea* in darker appearance, no bold white scapular spots; from *N. scutulata* in unstreaked underparts. Sexes similar, female slightly larger. **VOICE.** Most commonly a series of rising and accelerating "toi toi toi..."

notes, ending with lower-pitched "toi".

Habitat. Mainly primary lowland and hill forest to 1100 m, rarely to 2300 m; also tall secondary forest, woodland, forest edge and cultivated areas.

Food and Feeding. Almost no information on diet; one record of killing a fruit bat (*Thoopterus nigrescens*) caught in a mist-net. Forages singly or in pairs along streams in primary forest.

Breeding. Apparently undescribed; nestlings reported in Sept.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Widespread, but generally uncommon. Locally common, e.g. in Dumoga-Bone National Park; also occurs at Lore Lindu National Park.

Bibliography. Andrew (1992), van der Berg & Bosman (1986), Catterall (1997), Coates & Bishop (1997), Holmes & Philipps (1996), Rozendaal & Dekker (1989), Watling (1983), White & Bruce (1986).

176. Bismarck Hawk-owl

Ninox variegata

French: Ninox bariolée **German:** Bismarckkauz **Spanish:** Nínox de las Bismarck
Other common names: Bismarck Boobook, New Ireland Hawk-owl

Taxonomy. *Noctua variegata* Quoy and Gaimard, 1830, Carteret Harbor, New Ireland, Bismarck Archipelago.

Relationships unclear. Proposed treatments include as member of species-group that includes *N. boobook*, *N. novaeseelandiae*, *N. squamipila*, *N. theomacha*, *N. meeki* and perhaps other boobooks in Australasian Region; more research needed. Sometimes referred to, erroneously, as *N. solomonis*. New Hanover population sometimes separated as *superior*. Monotypic.

Distribution. New Britain, New Ireland and New Hanover, in Bismarck Archipelago.

Descriptive notes. 23-30 cm. Small, brown hawk-owl. Upperparts chocolate- or rufous-brown, with grey-brown head; white spotting or barring on mantle, scapulars and wing-coverts; flight-feathers and tail dark brown barred with lighter brown; underparts whitish, with dark brown or orange-brown bars; eyes yellow; feet dull yellow. Sexes similar, female slightly larger than male. Juvenile undescribed. **VOICE.** Crooning, somewhat frog-like, repeated, disyllabic "oo-oo".

Habitat. Forested lowlands, hills and lower mountains.

Food and Feeding. Presumably insects; habits little known.

Breeding. 1 newly fledged young in Apr; no other information.

Movements. Undescribed; presumably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in New Britain and New Ireland EBA. No data on population, ecology or biology; studies urgently required.

Bibliography. Coates (1985), Finch & McKean (1987), Jones & Lambley (1987), Mees (1964), Stattersfield *et al.* (1998).

177. New Britain Hawk-owl

Ninox odiosa

French: Ninox odieuse **German:** Neubritannienkauz **Spanish:** Ninox de Nueva Bretaña
Other common names: New Britain Boobook, Russet Hawk-owl/Boobook

Taxonomy. *Ninox odiosa* P. L. Slater, 1877, New Britain.
Relationships uncertain; seems to be most closely related to *N. jacquinoti*. Monotypic.
Distribution. New Britain, in Bismarck Archipelago.

Descriptive notes. 20-23 cm; female 209 g. Small, finely spotted hawk-owl with conspicuous white eyebrows and throat, crown lightly dotted; upperparts chocolate-brown, sprinkled with small buff-white spots; underparts mottled white and pale brown; iris yellow to orange-yellow. Differs from *N. variegata* by smaller size, white face markings, less patterned upperparts. Sexes similar, female slightly larger. Juvenile undescribed. **VOICE.** Rapidly repeated monosyllable, "who", typically starting low, then rising in pitch, becoming faster and louder.

Habitat. Forested lowlands and hills, to at least 800 m; also in cultivated areas, plantations and

towns. Roosts by day, singly or in pairs, in canopy.

Food and Feeding. Insects and small vertebrates.

Breeding. Undescribed.

Movements. Unknown; probably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in New Britain and New Ireland EBA. Appears to be quite common, but little studied; no information on numbers or on breeding biology.

Bibliography. Coates (1985), Diamond (1975), Finch & McKean (1987), Stattersfield *et al.* (1998).

178. Solomon Hawk-owl

Ninox jacquinoti

French: Ninox de Jacquinot **German:** Salomonenkauz **Spanish:** Ninox de las Solomón
Other common names: Solomon Boobook

Taxonomy. *Athene jacquinoti* Bonaparte, 1850, St George, Solomon Islands.

Relationships uncertain; probably closely related to *N. odiosa*. Subspecific divisions considered dubious by some, although most races appear fairly well defined; more research required. Seven subspecies recognized.

Subspecies and Distribution.

N. j. eichhorni (Hartert, 1927) - Buka, Bougainville and Choiseul.

N. j. jacquinoti (Bonaparte, 1850) - Ysabel and St George.

N. j. granti Sharpe, 1888 - Guadalcanal.

N. j. mono Mayr, 1935 - Mono I.

N. j. floridae Mayr, 1935 - Florida I.

N. j. malaitae Mayr, 1931 - Malaita I.

N. j. roseoaxillaris (Hartert, 1929) - Bauro and San Cristobal.

Descriptive notes. 23-31 cm. Small rusty-brown hawk-owl. Facial disc grey-brown, with thin indistinct whitish eyebrows and white throat band; upperparts rusty-brown with pale creamy-buff feather tips; breast buff-white with brown bars or spots; belly uniformly creamy; eyes yellow to orange-yellow; bill creamy-yellow. Distinguished from *N. theomacha* by barred breast and cream belly. Sexes similar, female slightly larger. Juvenile undescribed. Races vary in coloration and markings, also in size: *floridae* larger than nominate, with creamy face; *eichhorni* smaller, coarsely barred above; *mono* with

dark breast band; *granti* barred below, eyes sometimes brown; *malaitae* smallish, relatively unmarked; *roseoaxillaris* distinctive, very small, all cinnamon-rufous below with faint creamy vermiculations, axillaries pink, eyes yellow or brown. **VOICE.** Repeated single hoot, with rising inflection at end; pairs duet.

Habitat. Primary and tall secondary forest in lowlands and foothills, up to c. 1500 m. Roosts by day, singly or in pairs, in canopy or tree hollow.

Food and Feeding. Insects; probably also small vertebrates.

Breeding. No information.

Movements. No information; presumably resident.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Solomon Group EBA. Widespread within range, and apparently reasonably common. Research required on population size, ecology and breeding biology.

Bibliography. Buckingham *et al.* (1995), Cain & Galbraith (1956), Coates (1985), Diamond (1975), Hadden (1981), Mayr (1945), Schodde (1977), Stattersfield *et al.* (1998), Webb (1992).

Genus *UROGLAUX* Mayr, 1937

179. Papuan Hawk-owl

Uroglaux dimorpha

French: Ninox papoue **German:** Rundflügelkauz **Spanish:** Nínox Halcón
Other common names: Papuan Boobook(!), New Guinea Hawk-owl

Taxonomy. *Athene dimorpha* Salvadori, 1874, Sorong, New Guinea. Genus closely allied to *Ninox*; sometimes merged with latter, but wings more rounded. Monotypic.
Distribution. Irian Jaya and Papua New Guinea, including Yapen I; probably occurs throughout New Guinea, but known only from NW & SE.

Descriptive notes. 30-33 cm. Small-headed and long-tailed. Whitish facial disc finely streaked black, without distinct edge, and with white eyebrows; upperparts profusely barred brown (rusty to buffy) and black; underparts light buff, boldly streaked black and brown; large bright yellow eyes; grey to black bill. Juvenile paler than adult. Voice. Undescribed.
Habitat. Lowland rainforest, forest edge and gallery forest in savanna, up to at least 1500 m.
Food and Feeding. Insects, small rodents, and large to medium-sized birds; latter include e.g. Wompoo Fruit Dove (*Ptilinopus magnificus*), 80% of weight of owl itself.

Breeding. Downy fledgling seen in early Aug. No other information.
Movements. Unknown; probably resident.
Status and Conservation. Not globally threatened. CITES II. Data-deficient. Sparsely distributed throughout range, and rarely seen; appears to be rare.
Bibliography. Andrew (1992), Beehler *et al.* (1986), Clark & Mikkola (1989), Coates (1985), Hicks (1988b, 1990), Lamothe (1993), Peckover & Filewood (1976), Rand & Gilliard (1967), Shany (1995), Weston & Weston (1973).

Genus *SCELOGLAUX* Kaup, 1848

180. Laughing Owl

Sceloglaux albifacies

French: Ninox rieuse **German:** Lachkauz **Spanish:** Nínox Reidor
Other common names: White-faced Owl(!), Whekau

Taxonomy. *Athene albifacies* G. R. Gray, 1844, Waikouaiti, South Island, New Zealand. Genus perhaps most closely related to *Uroglaux*; closely allied to *Ninox*, if not congeneric. Probably a relict species. North Island population sometimes separated as race *ruffacies*, but claimed differences in plumage often not constant and size differences possibly clinal. Monotypic.
Distribution. Formerly occurred in mainly S half of North Island in areas of lower rainfall, in South Island E of Southern Alps but well into mountains, and on Stewart I.

Descriptive notes. 38-47 cm; c. 600 g. Medium-sized terrestrial owl with broad head, short wings, long tail and long legs. Forehead, sides of head and throat greyish-white with black feather shafts; facial mask white to light rufous, obvious but with ill-defined edges; upperparts rufous-brown, streaked dark brown, and with whitish to ochraceous feather edges; scapulars and wing-coverts dark brown, streaked and spotted yellowish-white; tail dark brown, barred yellowish-white; underparts deep ochraceous, broadly streaked dark brown; bill greyish horn; eyes very dark red-brown or hazel; legs feathered pale ochraceous; toes light brown, covered with dark hairs. Juvenile undescribed. Voice. Main call a loud, repeated "coo-ee" or "kee-wee"; laughing call prolonged "cack-cack-cack".

Habitat. Rocky valleys and cliffs in open country and temperate woodland; also scrub and forest edge.
Food and Feeding. Earthworms (Lumbricidae), insects, and small vertebrates such as birds, bats, rodents, frogs and lizards. Thought to have hunted mainly on ground, also from low shrubs and lower parts of trees; probably nocturnal and crepuscular.
Breeding. Little known. Laying late Aug-Oct. Nest in dry crevice among rocks or under boulders, cavity sometimes lined with dry grass, sedges, roots, etc. Usually 2 eggs, incubated by female; chick hatched in coarse yellow-white down.
Movements. Unknown: thought to be resident.
Status and Conservation. Almost certainly EXTINCT. CITES II. Once common and widespread. Decline, rapid after c. 1880 but first noticed in 1840's, coincided with settlement by Europeans, and was probably brought about by combination of habitat change and introduced predators (mustelids and domestic cats), along with human persecution. Species often claimed to have been extinct by 1914, when last specimen found dead, but alleged sightings or auditory records persisted until as late as 1950, and egg fragments found in South Island (Canterbury) in 1960; occasional reports from Stewart I (1970's) and South Island (1980's) have not been subsequently confirmed.
Bibliography. Anon. (1982a), Blackburn (1982), Buller (1887-1888, 1905-1906), Clark & Mikkola (1989), Eck & Busse (1973), Falla *et al.* (1981), Fuller (1987, 1999), Gill (1991, 1996), Greenway (1967), Heather & Robertson (1997), Higgins (1999), Holdaway (1996), Holdaway & Worthy (1996), Kinsky (1970), Knox & Walters (1994), Marples (1946), Myers (1923), Robertson (1985), Sayers (1998a), Shuker (1993), Smith (1884), Williams (1962), Williams & Harrison (1972), Worthy (1997), Worthy & Holdaway (1994a, 1994b, 1995).

Subfamily ASIONINAE

Genus *PSEUDOSCOPS* Kaup, 1848

181. Jamaican Owl

Pseudoscops grammicus

French: Hibou de la Jamaïque **German:** Jamaikaeule **Spanish:** Búho Jamaicano
Other common names: Brown Owl(!)

Taxonomy. *Ephialtes grammicus* Gosse, 1847, Tait-Shafton, Jamaica. Formerly merged with *Asio*; later suggested that closely related to *Asio clamator* and *Asio stygius* and that all three be placed together in *Pseudoscops*; more recent DNA studies, however, seem to confirm that present species better treated in monotypic genus (see page 86). Genus believed to be possibly closest to *Asio*, with similar contact calls, but often considered particularly close to *Otus*, while some authorities think that it is linked with *Athene* and *Aegolius*. Monotypic.
Distribution. Jamaica.

Descriptive notes. 27-34 cm. Ear-tufts conspicuous; well-developed facial disc rufous, edged white and black; upperparts rufous, finely vermiculated black; breast and belly rufous with narrow dark brown shaft streaks; flight-feathers and tail short, irregularly barred dark brown; dark eyes and light bluish-grey bill; naked grey toes. Juvenile lighter above, with back light greyish-brown, rest of plumage light dull cinnamon-buff. Voice. High, quivering hoot and guttural growl.
Habitat. Open woodland, forest edge, occasionally open parkland; enters gardens. Mainly in coastal and lowland areas, rarely in mountains.
Food and Feeding. Insects, especially beetles;

also mice, lizards and tree frogs. Nocturnal.
Breeding. Season probably Dec-Jun. Nest in cavity of large tree, or in tree fork concealed by vegetation; 2 eggs.
Movements. Resident.
Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Jamaica EBA. Considered common and widespread in Jamaica; ecology, however, remains little known and population status therefore difficult to assess. Extensive cutting of forest has probably reduced its range and numbers; advisable to monitor status while island's forest areas continue to be destroyed.
Bibliography. Anon. (1998a), Bond (1985), Downer & Sutton (1990), Olson (1995), Raffaele *et al.* (1998), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wiley (1986b).

Genus *ASIO* Brisson, 1760

182. Striped Owl

Asio clamator

French: Hibou strié **German:** Schreieule **Spanish:** Búho Gritón

Taxonomy. *Bubo Clamator* Vieillot, 1807, Cayenne. Often placed in monotypic genus *Rhinoptynx*, which has been merged with *Pseudoscops* by some; seems, however, to be very closely related to other *Asio* species, this supported by recent DNA studies. Race *forbesi* sometimes merged with nominate. Four subspecies recognized.

Subspecies and Distribution.
A. c. forbesi (Lowery & Dalquest, 1951) - S Mexico to Panama.
A. c. clamator (Vieillot, 1807) - Colombia and Venezuela S to E Peru and C & NE Brazil.
A. c. oberi (E. H. Kelso, 1936) - Tobago and NE Trinidad.
A. c. midas (Schlegel, 1862) - E Bolivia and S Brazil S to N Argentina and Uruguay.

Descriptive notes. 30-38 cm; male 320-350 g, female 400-500 g. Long black ear-tufts; facial disc mostly white, bordered black; upperparts cinnamon-buff, finely vermiculated and heavily striped blackish; flight-feathers and tail barred sooty-brown; breast and belly buff with black shaft streaks; dark eyes and grey bill. Juvenile has cinnamon face, bordered white and lightly streaked black, body plumage buff, barred greyish. Race *midas* larger, usually paler; *forbesi* small. Voice. Single, nasal hoot lasting c. 1 second, loudest and highest in middle, "hooOOoh" or "hnnNNNhh"; female higher-pitched; also 7-8 sharp, dog-like barks, "hu-hu! how! how!", sometimes given by mates in chorus. Juvenile has slightly shrill, whistled scream, "heeeen" or "hreeeh", repeated.

Habitat. Wide variety of habitats, from sea-level to 1400 m; tropical forest, forest edge, riparian woodland, savanna, marshes, rice fields, grassy clearings, scrub, thick hedges, woodland patches, agricultural and suburban areas, and sometimes plantations. Lives alone, in pairs or in groups; roosts in groups of up to c.12 individuals.
Food and Feeding. Mostly small mammals such as rodents (*Liomys*, *Calomys*, *Rattus rattus*, *Reithrodon auritus*, *Holochilus brasiliensis*), birds such as Eared Dove (*Zenaida auriculata*) and Grey-faced Quail Dove (*Geotrygon caniceps*), reptiles, and large insects such as long-horned grasshoppers (Tettigoniidae). Hunts by quartering low over open countryside, swooping after prey; also hunts from perch, dropping to ground.

Breeding. Lays Aug-Mar, but variable: Aug in Argentina, Sept-Oct in Surinam, Dec in Panama, late Jan-Feb in El Salvador. Nest in grassy clump on ground, on flat surface at no great height, or in tree. 3 eggs (2-4); incubation period c. 33 days; usually only 1 chick fledges.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Widespread, though local and uncommon, or patchily distributed; status generally poorly known, and little information on ecology and biology. Race *oberi* little known, may even be extinct.

Bibliography. Anderson *et al.* (1998), Belton (1984), Binford (1989), Canevari *et al.* (1991), Clark & Mikkola (1989), Contreras *et al.* (1990), Fraga (1984b), Friedmann (1927), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Howell, S.N.G. & Webb (1995a), Howell, T.R. 183. Stygian Owl

Asio stygius

French: Hibou maître-bois

German: Styxeule

Spanish: Búho Negruzco

Taxonomy. *Nyctalops stygius* Wagler, 1832, Minas Gerais, Brazil.

Has been proposed that species be included in *Pseudoscops*, but recent DNA studies appear to confirm its placement in *Asio*; very closely related to *A. otus*. Populations of NW South America usually placed in *robustus*, sometimes included in nominate; races *lambi*, *noctipetens* and *barberoi* poorly differentiated, possibly not valid. Six subspecies recognized.

Subspecies and Distribution.

A. s. lambi R. T. Moore, 1937 - W Mexican highlands (SW Chihuahua to Jalisco).

A. s. robustus L. Kelso, 1934 - from S Mexico (Guerrero and Veracruz) discontinuously to NW Venezuela, Colombia and Ecuador.

A. s. siguapa (d'Orbigny, 1839) - Cuba and I of Pines.

A. s. noctipetens Riley, 1916 - Hispaniola and Ile de Gonâve.

A. s. stygius (Wagler, 1832) - from N Brazil S to E Bolivia, NE Argentina and SE Brazil.

A. s. barberoi W. Bertoni, 1930 - Paraguay and N Argentina.

Descriptive notes. 38-46 cm; c. 675 g. Large, dark owl with prominent ear-tufts. Whitish forehead contrasts with blackish facial disc; upperparts blackish-brown, barred and spotted buff; underparts dirty buff, heavily streaked and barred dark brown; orange-yellow eyes, black bill; feet naked, toes bristled. Juvenile upperparts sooty-black, more or less mottled white or buff; underparts buff to yellow-buff, heavily spotted and streaked sooty-black. Race *robustus* paler, more spotted above; *siguapa* with markings whiter. Voice. Single deep, emphatic "bUuh", repeated at intervals of 6-10 seconds; female utters short, cat-like "miah".

Habitat. Montane pine and pine-oak forest, submontane evergreen forest, deciduous forest, humid Chaco woodland, *Araucaria*-dominated forest, *restinga* forest, parks and open areas with trees. From sea-level to 3100 m; in Mexico 1500-3000 m, in Belize 0-800 m, in Venezuela from 100 m, and in Colombia at 1700-3000 m.

Food and Feeding. Small mammals such as rodents and bats; also birds, reptiles, crustaceans and insects. Strictly nocturnal.

Breeding. Lays Nov-May. In Cuba nest found in tree, another on ground built with shredded palm leaves; as *A. otus*, will also use stick nest of other bird; 2 eggs.

Movements. Little known, probably largely resident; suspected visitor during Feb-Apr on Cozumel I, off NE Yucatán.

Status and Conservation. Not globally threatened. CITES II. Considered generally rare or patchily distributed; fairly common in W Mexico, uncommon to fairly common in Belize, rare and local in Colombia. Distribution incompletely documented. Subspecies on Caribbean islands rare and vulnerable, now confined to mountain forest; declines probably due to habitat loss, deforestation and association with ill omen. Protected in Dominican Republic, but still regularly killed in superstitious belief that it represents a witch; an education programme would benefit this species. Suffers some road casualties. Data on life history needed to develop conservation strategies.

Bibliography. Barbour (1943), Bates *et al.* (1992), Blendinger (1998), Canevari *et al.* (1991), Contreras *et al.* (1990), Dod (1992), Fjeldså & Krabbe (1990), Franz (1991), Hayes (1995), Hilty & Brown (1986), Howell & Webb (1995a), Howell *et al.* (1992), Kaufman (1997), Kirkconnell *et al.* (1994), Land (1970), Melo-Júnior *et al.* (1996), Meyer de Schauensee & Phelps (1978), Motta-Júnior & Taddei (1992), Oliveira (1981), Olrog (1985), Olson (1995), de la Peña (1994), Raffaele *et al.* (1998), Ridgely & Gwynne (1989), do Rosário (1996), Schaldach (1963), Scherer-Neto (1985), Sick (1993, 1997), Stotz *et al.* (1996), Voous (1988), Wetmore & Swales (1931), Wiley (1985, 1986b), Williams & Tobias (1994).

184. Northern Long-eared Owl

Asio otus

French: Hibou moyen-duc

German: Waldohreule

Spanish: Búho Chico

Other common names: (Common) Long-eared Owl

Taxonomy. *Strix Otus* Linnaeus, 1758, Sweden.

Forms superspecies with *A. abyssinicus* and *A. madagascariensis*, both of which have been treated as races of present species. Recent protein studies indicate unusually large genetic distance between present species and *A. flammeus*. Given nomadic tendencies of species, subspecific status of *tuftsi* questionable, possibly inseparable from *wilsonianus*. Four subspecies recognized.

Subspecies and Distribution.

A. o. otus (Linnaeus, 1758) - Eurasia, from British Is and Iberia E to Sea of Okhotsk, S to Mediterranean islands, Middle East, N Pakistan (has bred) and Japan, with isolated population in EC China; also Azores, and NW Africa (Morocco to NW Tunisia).

A. o. canariensis Madarász, 1901 - Canary Is.

A. o. tuftsi Godfrey, 1948 - W Canada (S Yukon, S British Columbia E to Saskatchewan) S to Mexico (NW Baja California, Nuevo Leon) and S USA (W Texas).

A. o. wilsonianus (Lesson, 1830) - from SC & SE Canada (Manitoba E to Nova Scotia) S in USA to N Oklahoma and Virginia.

Descriptive notes. Male 35-38 cm, 220-305 g; female 37-40 cm, 260-435 g; wingspan 90-100 cm. Medium-sized owl with large, round head and conspicuous ear-tufts. Rounded facial disc buff, with white inner eyebrows and lores; eyes orange, bill black; upperparts a mixture of black, brown, grey, buff and white; wings long and rounded, with buff patch above and dark carpal crescent below; underparts whitish-grey and buff with dark brown streaking and barring; tarsi and toes densely feathered. Sexes similar; female somewhat darker, especially on facial disc, more heavily streaked above, darker buff on underwing-coverts. Juvenile with facial disc, wings and tail as adult, rest of plumage greyish-buffed buff. Race *canariensis* darker than nominate; *wilsonianus* also darker, with more prominent barring below, rufous facial disc, yellow eyes, *tuftsi* similar but not so dark. Voice. Complex repertoire in breeding season; advertising song of male is series of 10 to over 200 "hooh" notes, evenly spaced about 2-4 seconds apart; common alarm call a barking "ooack ooack ooack". Mostly silent at other times of year.

Habitat. During breeding season, inhabits dense vegetation adjacent to open areas such as grassland or shrubland, including open forest, from near sea-level to 2750 m; nests and roosts in forest. In Idaho, large numbers nest in willows (*Salix*), cottonwoods (*Populus*) and junipers (*Juniperus*) adjacent to shrub-steppe desert; in dense or brushy vegetation in open habitats in SW & NW USA, and in coniferous or deciduous forest near open meadows in Michigan and W Oregon. In mainland Europe, breeds in edge woodland and scrub; in Britain prefers shelterbelts, small groves and thickets surrounded by moorland, grassland, marshes or farmland. In winter range, occupies similar habitats to those when breeding, including farmland with hedgerows; often in traditional sites, using same tree groves annually. Roosts communally during non-breeding season, typically 2-20 birds but can be up to 100.

Food and Feeding. Mainly small mammals; birds important in a few studies. Voles (*Microtus*) dominate diet in many areas of North America; in N Italy, switched to birds following heavy snowfall. Nocturnal; occasionally crepuscular, usually during breeding. Hunts below canopy in open forest; active-search hunter, courting back and forth with fast wingbeats, interrupted by short glides; occasionally hovers; adaptations for silent flight well developed, including comb-like fringe on leading edge of outer 2 primaries, soft, hair-like fringe on trailing edge of remiges, and downy surface on dorsal side of remiges. Sometimes hunts from perch, especially when windy. Probably locates most of prey by ear (can capture mice in complete darkness). Most food probably captured on ground or from low vegetation. Kills small mammals by biting back of skull. Swallows prey whole; may eviscerate rodents and leave entrails uneaten.

Breeding. Season Feb-Jul; in Netherlands, laying dates significantly earlier during peak vole years. Monogamous, occasionally polygynous; solitary, also with tendency to nest in small colonies. Uses abandoned stick nest of other bird, such as Common Raven (*Corvus corax*), also accepts artificial baskets; sometimes lays in cavity in tree or cliff, or on ground; site sometimes reused, often by different individuals. Male courtship involves zigzag flight around and through nest grove using deep wingbeats interspersed with glides and wing-claps; also advertising song, which may coincide with female's nest call. 5-7 eggs, occasionally more if food abundant; replacement laid if first clutch lost; incubation 26-28 days, by female, taking only short breaks at night; male feeds female throughout; hatching with eyes closed, covered with white protopluteal down, semi-altricial; chicks leave nest after 21 days, still flightless, to reside in surrounding vegetation ("branching" stage), where they roost apart, suggesting that "branching" is adaptation to reduce predation; capable of flight at c. 35 days; in Idaho study, during "branching" period, males made 2.5 times more food deliveries than females, latter fed young until 6-5-8 weeks old, then deserted, males continued to feed young for 2-3 weeks longer. Average number of young fledged per successful nest 3-4-5 (USA), 2-8-3-2 (Europe); occasional second broods in peak vole years; annual survival for adults 69% (Germany and Switzerland).

Age at first breeding 1 year. Longevity record in wild 27 years and 9 months. **Movements.** Resident and migratory; migration poorly understood. Nomadic in response to fluctuating prey numbers in N Europe: overwinters N to C Finland during years with abundant prey, otherwise migratory in most of Fenno-Scandia and across northernmost parts of Asian range; birds breeding in Europe may winter as far S as Egypt, but largely sedentary in S Europe; Azores and Canary Is populations non-migratory. Accidental Iceland, Spitsbergen, Bear I, Iraq and Kuwait; in China, breeds in N, winters in S; Asian breeders winter as far S as N India and Indochina. Spring and autumn movements in appropriate directions in USA suggest regular migration (1 ringed in Montana recovered in Guanajuato, Mexico, having travelled 3200 km); presumably a regular migrant in N Canada; commonly winters in breeding range throughout USA and extreme S Canada; accidental Alaska, Bermuda and Cuba.

Status and Conservation. Not globally threatened. CITES II. In Europe, highest densities of up to 20 breeding pairs/100 km² across lowlands of C parts and from N France to Ukraine and S Russia (e.g. Germany 35,000-80,000 pairs, Russia 50,000-500,000 pairs), declining rapidly with increasing latitude and altitude; e.g., Finnish population estimated at only 2500 pairs; similarly, far scarcer in Mediterranean Europe, consistently below 4 pairs/100 km². Fairly common in China. Numbers appear to fluctuate with rodent populations; however, has decreased in Britain and possibly elsewhere. Recent decline and irregular distribution in Britain coincide with expansion of *Strix aluco* resulting from upland reforestation, latter being physically dominant and with similar ecological requirements; increase reported in Ireland, where *S. aluco* absent. Will nest in artificial baskets and open-fronted nestboxes; artificial structures could mitigate loss of sites from reduction in corvid numbers. State listings in USA: endangered in Illinois, threatened in Iowa, and species of special concern in California, Montana, North Dakota, Wisconsin, Michigan, Missouri, and all New England states except Maine; likely factors regulating populations include fluctuating prey numbers, high nest predation and habitat changes; may be affected by nest availability, especially where corvid numbers reduced. Decline in S California attributed to loss of riparian and grassland habitats to development; in W USA, where much of nesting habitat occurs in narrow bands along watercourses, loss of riparian woodland and isolated tree groves would be highly detrimental; maintenance of healthy riparian stands would undoubtedly be beneficial. In New Jersey, loss of open habitats to urbanization and forest succession thought to limit numbers; preservation of grassland and marshes, and planting of conifers near open habitats, considered important management actions.

185. African Long-eared Owl

Asio abyssinicus

French: Hibou d'Abyssinie **German:** Afrika-Waldohreule **Spanish:** Búho Abisinio
Other common names: Abyssinian/Ethiopian (Long-eared) Owl

Taxonomy. *Otus abyssinicus* Guérin-Méneville, 1843, Eritrea. Forms superspecies with *A. otus* and *A. madagascariensis*. Has been treated as race of *A. otus*, but considered specifically distinct on grounds of biometrics, and plumage and vocal differences. Race *graueri* sometimes considered inseparable. Two subspecies recognized.

Subspecies and Distribution.

A. a. abyssinicus (Guérin-Méneville, 1843) - Highlands of Ethiopia and Eritrea.
A. a. graueri Sassi, 1912 - Ruwenzori and Mitumba Mts in E Zaire/W Uganda, and Mt Kenya.

Descriptive notes. 42-44 cm. Head buffy, with dark brown bars, and long brown ear-tufts edged white; facial disc pale to dark buff-rufous, with distinct light grey eyebrows; upperparts brown with dark brown, buff and white vermiculations; flight-feathers and tail barred brown and buff; breast pale buff or more rufous, with thick brown, broken bars; lower belly pale buff or ivory with closely spaced brown streaks and cross-bars, giving chequered effect; eyes yellow; bill black. Distinguished from *A. otus* by larger size, chequered appearance of underparts, darker plumage, and more powerful feet and bill. Juvenile undescribed. Race *graueri* greyer overall and

slightly smaller than nominate race. **VOICE.** Deep, soft hoot, "ooo-ooooom", drawn out and rising in pitch, also "whooh"; female softer and higher-pitched; also barking call and high squeal when alarmed. **Habitat.** Open woodland and grassland with patches of cedar and oak forest, over 3000 m; in Ethiopia, also exotic plantations in similar habitats. Roosts in dense foliage, e.g. in giant heath; where food abundant, sometimes large communal roosts of up to 30 individuals.

Food and Feeding. Small mammals, including shrews (Soricidae), mole rats (*Tachyoryctes*) and rats, probably forming c. 90% of diet; occasionally takes small birds or invertebrates, usually in summer if small mammals not abundant. Stronger, larger feet and bill than *A. otus*, allow exploitation of larger prey. Strictly nocturnal; can spend up to 2-5 hours per night hunting. Hunts over open country, by quartering 0.5-1.5 m above ground; sometimes locates prey from perch; relies on keen hearing for hunting.

Breeding. Few data. Lays perches Jan-Jun; probably uses old stick nest of bird.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Scarce to rather rare throughout range. Nominative race regularly recorded at Bale Mountains National Park, Ethiopia. Race *graueri* rare on Mt Kenya; known from only 1 specimen, but sighted in 1992.

Bibliography. Britton (1980), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Kemp & Kemp (1998), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Præd & Grant (1957, 1970), Olson (1995), Shirihai & Francis (1999), Short *et al.* (1990), Snow (1978), Tilahun *et al.* (1996), Turner (1976), Yalden (1973), Zimmerman, D.A. *et al.* (1996).

186. Madagascar Long-eared Owl

Asio madagascariensis

French: Hibou malgache **German:** Madagaskar-Waldohreule **Spanish:** Búho Malgache
Other common names: Madagaskar/Mascarene Owl

Taxonomy. *Otus Madagascariensis* A. Smith, 1834, Madagascar.

Forms superspecies with *A. otus* and *A. abyssinicus*. Has been treated as race of *A. otus*; considered specifically distinct on grounds of historic isolation, smaller size, darker eyes and more orange-yellow plumage. Monotypic.

Distribution. Madagascar.

Descriptive notes. 31-36 cm. Head dark brown, flecked with tan; long, similarly coloured ear-tufts; buffy-tan facial disc, turning to dark brown around deep, dull orange eyes; bill black; upperparts vermiculated and spotted brown, tan and black; flight-feathers and tail barred brown and buff; breast and belly light buffish with dark brown shaft streaks, becoming more widely spaced and arrow-shaped towards belly. Sexes similar, female larger. Juvenile with white down and contrasting black facial mask; ear-tufts fully visible. **VOICE.** Long series of barking "han kan, han kan" notes, accelerating and increasing in volume, dropping and fading at end; also lilting "uloooh", repeated at intervals.

Habitat. Humid evergreen forest, dry deciduous forest and gallery forest; also dense secondary woodland, including degraded habitats; observed from sea-level to c. 1600 m, occasionally to 1800 m. Roosts in thick vegetation during day.

Food and Feeding. Mainly mammals, including rats (*Rattus*) and lemurs (Lemuridae), with great proportion of diet introduced rodents; also takes free-tailed bats (*Tadarida*); occasionally reptiles, birds and insects. Long powerful claws for its body size. Strictly nocturnal. Hunts in forest and also in adjacent open areas.

Breeding. Little information. Lays Aug-Oct, perhaps in old stick nest of other bird; 3 young observed in Mar in forest area.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Status difficult to assess because of secretive and nocturnal lifestyle; may be overlooked. More commonly seen in E at Andapa, Maroantsetra, Sihanaka forest, Andasibe, Ranomafana, and forest of Sambirano and Montagne d'Ambre, on High Plateau; and at Morondava and Berenty in W and S. Persecuted by villagers, who regard it as an evil omen; in 1982, dead adult seen nailed up on outskirts of a village. May be threatened by deforestation, which is extensive in Madagascar.

Bibliography. Benson *et al.* (1976-1977), Dee (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Goodman, Creighton & Raxworthy (1991), Goodman, Langrand & Raxworthy (1993a, 1993b), Kemp & Kemp (1998), Langrand (1994, 1995), Langrand & Goodman (1996), Milon *et al.* (1973), Morris & Hawkins (1998), Olson (1995), Rand (1936), Rasoloarison *et al.* (1995), Safford & Duckworth (1990), Sinclair & Langrand (1998), Snow (1978).

187. Short-eared Owl

Asio flammeus

French: Hibou des marais **German:** Sumpfohreule **Spanish:** Búho Campestre

Taxonomy. *Strix Flammea* Pontoppidan, 1763, Denmark.

Morphologically similar to *A. otus*, but recent studies of proteins indicate unusually large genetic distance between them. Sometimes thought to be closely related to *A. capensis*, which replaces it ecologically in Africa, but resemblance seems superficial and probably due to convergence, and vocalizations very different. Much darker race *galapagoensis* possibly specifically distinct. Race *domingensis* was formerly considered a separate species, including *portoricensis* as a race; alternatively, these two have been considered a single race of present species. Ten subspecies recognized.

Subspecies and Distribution.

A. f. flammeus (Pontoppidan, 1763) - breeds Iceland, British Is, and locally through Europe and Asia E to Kamchatka and Commander Is, S to Spain, Caucasus, NE Mongolia and NE China; also North America from W & N Alaska through Canada and S to C USA.

A. f. ponapensis Mayr, 1933 - Pohnpei I, in E Caroline Is.

A. f. sandwichensis (Bloxham, 1826) - Hawaiian Is.

A. f. domingensis (P. L. S. Müller, 1776) - Hispaniola; also (possibly this race) Cuba.

A. f. portoricensis Ridgway, 1882 - Puerto Rico.

A. f. pallidicaudus Friedmann, 1949 - N Venezuela, Guyana.

A. f. bogotensis Chapman, 1915 - Colombia, Ecuador, NW Peru.

A. f. galapagoensis (Gould, 1837) - Galapagos Is.

A. f. suinda (Vieillot, 1817) - S Peru, WC Bolivia, Paraguay and SE Brazil S to Tierra del Fuego.

A. f. sanfordi Bangs, 1919 - Falkland Is.

Descriptive notes. Male 37cm, 200-450 g; female 38 cm, 280-500 g. Medium-sized owl with distinctive moth-like flight, wingbeats bouncing, high and flapping. Head large and round, with very small tufts, generally unseen, arising from centre of forehead; large, round facial disc grey-white, with black around eyes, white chin, and facial ruff and forehead white, brown and buff; upperparts mottled brown and buff, resembling dried grasses; wings long and broad, with pale ochre patch outside carpal region; central tail-feathers with brown blotching within buff area between 5-6 dark horizontal bars; underparts whitish to pale buff with dense vertical breast streaks, thinning out on sides and flanks; underwing with dark wrist markings, otherwise generally buffish-white throughout, with blackish tips; eyes yellow; bill black; thighs and feet whitish-buff. Female browner above, more buff below, more heavily streaked, larger. Juvenile has crown and rump dark brown, facial disc brown-black with feathers tipped buff, mantle with incomplete buff bars, and underparts warm buff. Races differ mainly in depth of coloration: *sandwichensis* much paler and greyer; *galapagoensis* very dark, with black face mask, streaked and barred below. **VOICE.** Generally silent, but during courtship male gives series of 13-16 notes in flight, "hoo-hoo-hoo-hoo-hoo-...", various barking calls heard in winter or during human territorial intrusion, also "kee-ow".

Habitat. Open country: tundra, marsh, grassland, savanna, moorland; also montane forest. In North America, associated with open country supporting small mammals with population cycles, such as voles and lemmings; large expanses of prairie and coastal grassland, heathland, shrub-steppe and tundra; also agricultural areas. In Europe, breeds mainly on tundra, moorland, marshes and bogs, in newly cleared forest and young evergreen plantations, in uncultivated grassland and in steppe. In China, tundra, steppe, meadows, sand dunes and marshes. Roosts primarily on ground, occasionally in trees or low bushes; in winter usually in groups. Occurs from sea-level to uplands, in Andes to as high as c. 4000 m.

Food and Feeding. Small mammals, less frequently birds. Mammals commonly include voles (*Microtus*), shrews (*Sorex*), moles (*Scapanus*), rabbits and hares (*Oryctolagus*, *Lepus*), pocket gophers (*Thomomys*), jumping mice (*Zapus*) and deer mice (*Peromyscus*), less commonly bats (e.g. *Eptesicus*) and mustelids. Birds eaten in low numbers, more at coastal than at inland sites; in analysis of nearly 10,000 pellets, 94-8% of diet mammals and 5-1% birds. Diurnal, crepuscular and nocturnal; activity probably dictated by prey density and by hunger of adults and nestlings. Hunts low above ground, often quartering with wings held in slight dihedral, or hovering and quickly adjusting flight to drop on to prey; can use auditory cues to locate prey; low wing-loading facilitates slow flight speed, aerial agility, reduced aerodynamic flight noise, ability to hear while in flight, and reduced detection by prey; can also rely on vision. In one study, of 628 foraging attempts, 21% successful, 70% unsuccessful, 9% outcome unknown. Swallows small mammals whole, or clips off head and eviscerates by pulling out trachea and oesophagus region; clips wings off birds, then swallows them whole.

Breeding. Lays Mar-Jun in N hemisphere; breeding begins Sept in S hemisphere. Seasonal monogamy, though polygamy suspected. Nest on ground; in North America in dry site with enough vegetation to conceal incubating female, often on slight ridge or mound, female scrapes out bowl and lines it with grasses and downy feathers; in Europe also dry site, sometimes in wetter situation, and female shows tendency to build nest (almost unique behaviour among Strigidae). Pair-bonding

begins late winter, male performing sky-dancing display with song, aerobatics and wing-clapping. 5-10 eggs, average clutch size 5-6 in North America, 7-3 in Europe; female incubates and broods, may retrieve eggs from outside nest by hooking bill under and rolling them back; male feeds female, and defends nest with distraction displays and vocalizations; incubation period 26-29 days; chick hatches with eyes closed, egg tooth present, with buffy down; young leave nest at c. 12-18 days, unable to fly, hide in vegetation; fledged young form communal family group and roost together during day, parents may participate at first, but sex roles and duration not known; in Europe, young not independent until 50 days after leaving nest. Hatching success variable: in Montana, of 235 eggs laid, 174 (74%) hatched, yielding c. 5-8 hatchlings/nest; in Germany, 44 (36-4%) of 121 eggs hatched from 17 nests; predation, annual fluctuations in prey density, habitat changes and catastrophic events can all contribute to wide variation in reproductive success; sometimes raises second brood. Breeding age from 1 year or less. Longevity record in wild c. 13 years. **Movements.** Thought to be highly migratory in N part of range, though migration perhaps confused with nomadic food searches and juvenile dispersal; also, wintering areas may become breeding areas if food plentiful. Although present throughout year in middle latitudes, ringing data indicate seasonal N-S and W-SW migration: bird ringed in Oklahoma recovered in Saskatchewan, 1891 km NNW; 1 ringed in British Columbia recovered 1730 km SSE in California. In Europe and Asia, migratory in N of range: N populations winter from British Is, S Scandinavia and C Asia S to N half of Africa and parts of S & E Asia; known to breed in N China and winter in S China. Accidental Spitsbergen, Bear I, Jan Mayen, Azores, Madeira and Cape Verde Is.

Status and Conservation. Not globally threatened, CITES II. In Europe, strongholds are in Scotland, Norway, Sweden, Finland, Belarus and Russia, with much smaller but locally important populations in most other countries S to Spain, Croatia and Caucasus. Best estimate of Fennoscandian population c. 12,500 breeding pairs, but highly variable depending on cycles of rodent prey; territory size may be as small as 10 ha. Much breeding in C & S Europe erratic, perhaps only when vole numbers peak or when many birds driven S from N regions by food shortages. Moorland afforestation in N Britain and elsewhere has provided ideal but temporary nesting habitat, holding abundance of rodent prey: Dutch polder reclamation had similar effect, supporting 2000-3000 owls in late 1940's, but such peaks transient. General decline through C Europe caused by drainage and intensification of agriculture, together with persecution, rodenticide poisoning, urbanization and traffic mortality. Present European total estimated at 9000-35,000 pairs, plus 10,000-100,000 pairs in Russia, where species has declined by over 50% since 1970. In North America, populations declining in many areas: considered rarest and most threatened owl in NE USA, where listed as endangered, threatened or species of special concern in 7 of 13 states; also significant declines in NW USA (parts of Idaho, Oregon and Washington). In Cuba, where formerly considered a vagrant, and in Hispaniola, dramatic increase in recent decades; now common year-round resident on both islands. Nesting habits and nomadism render species particularly vulnerable to habitat loss at any season; conversion of open habitats to agriculture, grazing, recreation, housing and resort development is a key factor in decline; reforestation in some areas may also contribute to habitat loss. Throughout range, apparently suitable habitat often not occupied, suggesting that factors other than habitat loss, probably levels of prey or predation, affect distribution and abundance. Disturbance by domestic and feral cats and dogs is known to occur; predation by skunks on eggs and nestlings suspected in decline in Massachusetts, where management suggestions have included establishing standardized survey protocol, maintaining large continuous tracts of habitat for species and its prey, monitoring predation and human disturbance, public education and research. Species has benefited indirectly from protection of nesting cover for waterfowl and from reclaimed and replanted strip-mines and dyke land, which provides nesting and foraging cover.

188. Marsh Owl

Asio capensis

French: Hibou du Cap

German: Kapohreule

Spanish: Búho Moro

Other common names: African Marsh Owl

Taxonomy. *Otus Capensis* A. Smith, 1834, Waaipiaats, Martindale, Cape Province. Sometimes thought to be closely related to *A. flammeus*, the two replacing each other ecologically; any resemblance, however, rather superficial and probably due to convergence, and voices also very different. Three subspecies recognized.

Subspecies and Distribution.

A. c. tingitanus (Loche, 1867) - NW Morocco.

A. c. capensis (A. Smith, 1834) - isolated areas in W Africa, from Senegal to Chad and Cameroon; also from S Sudan and Ethiopian Highlands, and from S Congo, S to the Cape.

A. c. hova Stresemann, 1922 - Madagascar.

Descriptive notes. 29-36 cm; wingspan 82-99 cm; 225-375 g. Round-headed, with dark areas around eyes, inconspicuous ear-tufts in centre of forehead. Uniformly brown above, except for buff tail-bars and similar buff patches in outer primaries; dark secondaries with buffy edges; dark, barred underparts; eyes dark brown; bill grey with black tip. Female larger and darker than male. Juvenile has darker facial disc

outlined in black. Race *tingitanus* darker than nominate and with rufous markings, especially on underparts, contrasting with white spotting; *hova* larger, with more distinct bars overall. **Voice.** Loud croaking "creeoww" when flushed, when circling overhead, in courtship, and on ground; also faster, repeated croaks, with female calling on higher pitch.

Habitat. Moist, coastal grassland and ephemeral marshes, up to montane grassland at 3000 m; variations in yearly rainfall continually alter habitat and distribution; may extend into dry grassland and bushveld. Sea-level to 1500 m in Madagascar.

Food and Feeding. Extremely varied diet suggests opportunist: small mammals, including bats; medium-sized mammals such as hares (Leporidae) and polecats (Mustelidae); also birds, frogs, lizards, scorpions, beetles and termites; often caches prey. Crepuscular and nocturnal. Hunts by quartering a few metres above ground with slow, steady wingbeats, alternating with short glides; may hover briefly and dive at prey; occasionally pursues on foot or aerially; hunts from perches if available.

Breeding. In N Africa lays Feb-Oct, peaking in Mar; Sept-Nov in SW Africa. Nest a shallow, unlined scrape near centre of grass tussock, often under overhanging grass; defended territory usually c. 80 ha, but pairs sometimes nest as close as 75 m, or territory as much as 2 km². Male displays at dusk, flying high with deep wingbeats and clapping wings below body. Usually 2-3 eggs (up to 6); failed early clutches sometimes replaced; female incubates and broods young, while male brings food; incubation period c. 28 days, eggs hatching asynchronously; young leave nest at 14-18 days, fledge at c. 35 days. Success higher in dry years; possibly 2 broods in years of prey abundance.

Movements. Partially migratory; wanders to uncertain extent outside breeding season. May leave areas during wet season; confirmed non-breeding wet-season visitor to coastal Gambia. Also nomadic when habitat destroyed by grass fires or drought; often local irruptions of considerable numbers with changes in suitable habitat, packing into communal roosts of up to 100 owls, though usually 15-30. Vagrants recorded in Spain, Portugal and Canary Is.

Status and Conservation. Not globally threatened. CITES II. Nominate race likely to be found where suitable habitat exists; occurs in a considerable number of protected areas throughout range. Moroccan race *tingitanus* rare within very limited range, numbers having decreased to an estimated 50-140 pairs owing to habitat changes; occurs at Merja Zerga Nature Reserve; in mid 19th century recorded in Algeria, but status uncertain and no subsequent records. Race *hova* in Madagascar uncommon and irregularly distributed. Fires during dry season destroy habitat, while grazing or thack-cutting may affect habitat quality. Nests often destroyed by fire, livestock, flooding, or predators such as mongooses (Herpestidae). Adults frequently killed by traffic, or become entangled in barbed-wire fences.

Genus *NESASIO* J. L. Peters, 1937

189. Fearful Owl

Nesasio solomonensis

French: Hibou redoutable

German: Salomoneneule

Spanish: Búho de las Salomón

Taxonomy. *Pseudotynx solomonensis* Hartert, 1901, Santa Isabel, Solomon Islands.

Affinities uncertain. Sometimes combined with *Asio*, and usually recognized as offshoot, but more likely a primitive or relict form. Monotypic.

Distribution. Solomon Is, on Bougainville, Choiseul and Santa Isabel.

Descriptive notes. c. 38 cm. Medium-sized, robust owl with powerful beak and talons. Pale rufous facial disc, blackish around eyes, and white eyebrows; crown and upperparts dark brown, mottled rufous; flight-feathers and tail distinctly barred rufous and brown; underparts deep ochre with narrow dark brown streaks; eyes yellow, bill black; legs feathered, feet grey. Sexes similar, female slightly larger. Juvenile undescribed. **Voice.** Single drawn-out note with ghostly, mournful human quality, rising in pitch at end.

Habitat. Mostly primary and tall secondary lowland and hill forest, to c. 500 m.

Food and Feeding. Mainly phalangers, especially *Phalanger orientalis*, and possums; also medium-sized birds.

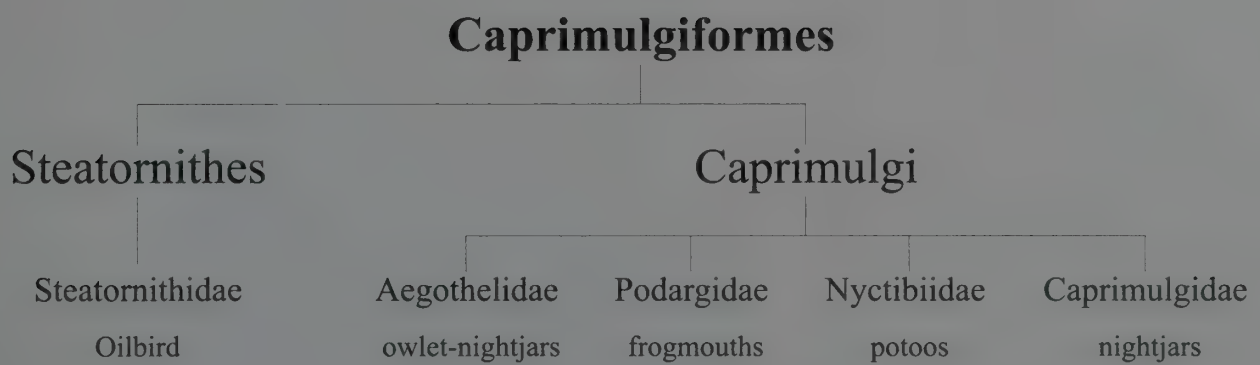

Breeding. No information available.

Movements. Probably sedentary.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in Solomon Group EBA. Generally rare and local, and wary of humans; thus little known. Probably threatened by forest destruction.

Bibliography. Clark & Mikkola (1989), Coates (1985), Collar *et al.* (1994), Diamond (1975), Gardner (1987), Hadden (1981), Kaestner (1987), Mayr (1945), Olson (1995), Peters (1937), Shaker (1993), Stattersfield *et al.* (1998), Webb (1992).

Order CAPRIMULGIFORMES

Class AVES
Order CAPRIMULGIFORMES
Suborder STEATORNITHES
Family STEATORNITHIDAE (OILBIRD)

- Large nocturnal fruit-eating birds, with hooked bill, wide gape, long wings and tail, and short legs.
- 40-49 cm.

- NW South America to Trinidad.
- Roosts and nests gregariously in caves, locally from sea-level up to 3400 m; feeds in subtropical forests.
- 1 genus, 1 species, 1 taxon.
- No species threatened; none extinct since 1600.

Systematics

Alexander von Humboldt was the first scientist to see the Oilbird (*Steatornis caripensis*) in its native habitat in 1799, but he did not publish a detailed report of this encounter until 1817, and it was only much later in the nineteenth century that European anatomists received enough specimens for them to study and attempt to classify. The Oilbird's affinities to the typical owls (Strigidae) and the nightjars (Caprimulgidae) seemed clear from the beginning and were never seriously questioned, largely because of their similar plumage and nocturnal foraging behaviour. The problem was the degree of relationship to these two groups, and even, by extension, of the Caprimulgiformes to the swifts (Apodidae). A study of the pterylosis of the Oilbird suggested a close relationship with the owls, yet clearly the owl foot, used in the capture and manipulation of food, is quite different from the small leg and weak foot of the Oilbird. The Oilbird's skeleton was found to be most similar to that of the potoos (Nyctibiidae). Other anatomists have linked the Oilbird to the rollers (Coraciidae), trogons (Trogonidae) and cuckoos (Cuculidae), and Humboldt even suggested a relationship with a passerine species, the Alpine Chough (*Pyrrhocorax graculus*).

The idea that the Oilbird belongs somewhere within the Caprimulgiformes is nowadays generally recognized, and this has been supported by studies using egg-white protein. Most systematists have tended to place it next to the owls, at the beginning of the Caprimulgiformes, and it is usually believed to be an early offshoot of the order. Its closest affinities may be with the potoos and nightjars, although neither of these appears to be a particularly near relative, so the Oilbird is almost always isolated in its own family, Steatornithidae.

The fossil history of ancestral steatornithids suggests that they may have been widely distributed in a very early radiation of birds over much of the Northern Hemisphere, perhaps as early as the Paleocene. Two nearly complete skeletons from the early Eocene, about 50 million years ago, have been recovered in the Fossil Butte of the Green River Formation in Wyoming, USA. Although these fossils are smaller than the extant Oilbird, they conform closely with it in having an unusually short and stout humerus, a shortened tarsometatarsus with a weak foot and claws, a large hooked bill with a very wide gape, and a large head. These fossils, belonging to a species that has been named *Prefica nivea*, share some features with early rollers; also, they have a more primitive sternum and pelvis than does *Steatornis* and less specialized structure of the humerus, toes and tail. This suggests that the fossil form was not

adapted either for life in caves or for hovering flight, which are both distinctive forms of behaviour of the present-day Oilbird.

Most interesting is that some of the same families and even genera of angiosperm plants in the contemporary Oilbird's diet were found as fossils in the same subtropical Green River Formation. It has been postulated that the early steatornithid *Prefica nivea* may similarly have eaten the fruit and then disseminated the large seeds of these same trees (see Food and Feeding).

Another fossil related to the Oilbird was found in south-western France in the Phosphorites du Quercy, dating from the Upper Eocene to the Lower Oligocene. The French and Wyoming fossil sites of early steatornithids are remote from the present entirely Neotropical distribution, which suggests that the extant Oilbird is a relict species.

Even though it is thought that the family may have diverged from other caprimulgiforms very long ago, its relationship to them remains unequivocal. Nearly all caprimulgiforms have very short tarsi, triangular hooked bills with long rictal bristles, and wide to very wide gapes. All are also nocturnal. The Oilbird differs mainly by its exclusively frugivorous diet, since all other caprimulgiforms studied to date are essentially insectivorous.

A reasonable hypothesis may explain the fossil distribution in Wyoming and France, compared with the family's present distribution in north-west South America, stretching north to Panama and east to Trinidad and Guyana. North American climatic changes in the Pleistocene could have forced ancestral steatornithids to migrate south following the retreat of their food trees, and on into South America after the Central American landbridge was formed. There they would have lived during the fluctuating climate of the late glacial periods. However, sequences of more favourable (wetter) and less favourable (drier) climatic conditions that prevailed in South America at that time affected the forest habitat, including the fruiting trees on which the Oilbird is totally dependent. Possibly during times of less favourable conditions some population segments became isolated. This would have reduced normal gene flow, and could have created the genetic bottleneck which researchers have identified in the present-day Oilbird. Alternatively, the homogeneity of genes could be a result of the Oilbird's capacity for far-ranging dispersal (see Movements).

Morphological Aspects

The Oilbird is a large chestnut-brown bird of 40-49 cm, weighing 350-485 g, and with a wingspan of more than a metre. The female

With its legs and swift-like pampodactyl feet placed well forward, the Oilbird has a rather cumbersome, top-heavy look when perched. The species shows the typical dull, cryptic plumage of nocturnal birds, though this is punctuated with well-marked white spots along the leading edge of the wing that may help the birds to detect one another when they are flying around in poor light conditions, as is their wont.

[*Steatornis caripensis*,

is slightly smaller than the male. The male is a greyer, slightly darker brown, whereas the female is paler and more rufous. Some birds have a greyish flush or sheen on the upperparts, while all are paler brown below. The underparts are speckled with white diamond-shaped spots, finely edged black, these spots being smaller on the throat and becoming larger toward the vent; in addition, there are small diamond-shaped spots on the head and, in some birds, on the uppertail-coverts. The Oilbird has ten primaries, twelve secondaries and ten rectrices; these feathers are also chestnut, but some are darker brown and, to a varying degree, most are banded with blackish lines broadly edged with a black speckled area.

Most outstanding are rows of large white spots which occur on the outer two primaries, the outer two secondaries, and the outer two tail feathers on each side. The carpal edge of the wing is white, and a highly conspicuous line of large white spots is found on the upperwing-coverts. All of the spots are further accented with blackish edging. In faint nocturnal light these white spots would give each bird highly visible warning lines, especially on the long wings. The Oilbird's wing bones are reported to be quite thin for the size of the bird, so the business of avoiding collisions with other conspecifics could be particularly important. Visually outstanding warning lines might be all the more advantageous to a large bird that forages silently in close groups at clumped fruit in trees at night (see Food and Feeding). Other social nocturnal-flying birds, such as migrating warblers, do not need to fly so close together and generally fly roughly parallel to each other.

The Oilbird's feathers are soft, as in most night-foraging birds, but not so silky and soft-edged as in either the Strigidae or Caprimulgidae, families of birds that depend on silent flight to catch living prey. Oilbirds can fly very slowly, hover, and turn and twist with agility, all of which contribute to their ability to manoeuvre within the narrow passages of caves. In flight at night in the open, the silhouette has been described as falcon-like, and birds have been reported sometimes to dive down like falcons with their wings half closed.

Distance flight speed has been reported to be 20-25 km/h, not very fast. The main importance of flight speed for the Oilbird is that it would limit how far a bird could fly in a single night, still making enough round-trips from fruiting trees to feed nestlings in caves.

Like vultures, Oilbirds have deep wingtip slotting to reduce stalling speed, and the wing is deeply cambered to give it lift at low speed. The birds have low wing-loading (body weight to wing area), and a low aspect-ratio (wingspan to wing width). These features are aerodynamic advantages for flying slowly, and for carrying heavy loads such as a stomachful of large-seeded fruits. The plum-

age structure and its particular modifications to allow slow hovering at fruiting trees have been suggested as pre-adaptations to ledge-nesting and ledge-roosting, where hovering is also important. Echolocation, for which the birds are famous, is used only in dark caves, and may be a more recent adaptation (see Voice).

The tail is long and graduated, with unstiffened feathers. An unusual tail arrangement, which involves its being held in an inverted V with the outer rectrices lower, appears to be another adaptation for hovering at fruiting trees, and also probably when approaching nests and roosting ledges. Oilbirds watched feeding in Peru were described as rhythmically elevating and depressing the tail, as some hummingbirds do when feeding: the downward movement of the inverted V-shaped tail generates lift, while the upward movement meets with relatively little air resistance.

The very short unscaled tarsus has a few bristle-like filoplumes. The legs are set far forward, and when the bird is perched on its nest or on an adjacent shelf in a cave, it appears to tip awkwardly forward. The anisodactyl foot has three toes pointing forwards with the hallux at a right angle to the middle toe; in the past, the Oilbird's foot was erroneously reported to be pampodactyl, like that of swifts (see page 391), with all four toes pointing forwards. The Oilbird's toe arrangement and flexible tail do not permit it to perch scansorially like woodpeckers, or to cling firmly to vertical surfaces like swifts, although it will occasionally cling briefly to cave walls. It does, however, aid nestlings, that fall or get pushed over the edge of a nest, to claw their way back to safety using the feet, bill and wings. On nests and ledges, the birds can shuffle about, but a single foot seems too weak to support the bird when it scratches its head without the support of one or both wings against the substrate.

The bill, although wide and triangular at the base, is thin and hawk-like toward the tip. On each side of the bill are 10-12 long (3-5 cm) rictal bristles, or vibrissae, directed forward and probably aiding the birds tactilely in both fruit selection and nest attendance, all aspects of which are commonly performed in the dark. The gape is very wide and can accommodate fruits of more than 6 cm in diameter. The upper mandible has a single notch, presumably as an aid in grasping and pulling off large fruits from trees. The Oilbird has a double bronchial syrinx, as in both owls and nightjars.

As soon as an Oilbird flies out of its cave it uses its eyes because the sonar, or echolocation clicks, stop abruptly. In addition to its special adaptations to the dark, the Oilbird may have good night vision. The eyes are brown, not blue as reported by Humboldt, an error that has lingered in the literature, but when spotlighted they appear bright red, as can be seen in many flash photographic pictures. Both above and below the eyes are rows of stiff bristles.

The Oilbird has an enlarged and heavily innervated olfactory organ, with very thick mucous membranes, and a nasal chamber conformation particularly adapted to carrying an airstream to these membranes. This highly developed olfactory morphology is assumed to give it a keen sense of smell, a rare feature in the class Aves that is found, for example, in kiwis (Volume 1, page 104), some petrels (Volume 1, page 218), and cathartid vultures (Volume 2, page 27), all of which also have olfactory adaptations to particular environmental circumstances. Many of the fruits that the Oilbird depends on have a highly aromatic odour (see Food and Feeding). Also, the slightly musty odour of the birds themselves has been suggested as a possible aid in individual recognition. The Oilbird has a bare oil-gland that is relatively large in relation to the bird's mass, as compared with those of both owls and nightjars.

Moult in the Oilbird has been little studied due to the difficulty in tracking individual birds, and the subsequent disturbance that handling causes to breeding birds. Nevertheless, D. Snow found that Oilbirds, like most birds, moult following breeding. Primary moult is exceedingly slow, and frequently lasts into the next breeding season; indeed, there is even some evidence that birds may begin a second primary moult before the first is completed. The moult is generally outwards from the innermost primary, but several birds were found moulting primaries from two different centres. Some moult takes place in every month of the year.

Habitat

Caves used for breeding and roosting in are considered to be the main population-limiting resource. However, it is also becoming increasingly clear that the forests used by the birds for their foraging may prove to be the more seriously threatened asset.

The Oilbird is found only in the Neotropics, from sea-level up to 3400 metres. In Trinidad and Venezuela a few sea caves have roosting and breeding populations, but these caves are not far from rich hill forests, the source of food. The combination of acceptable fruit trees and suitable caves within nightly commuting distance is not common. Apparently lacking enough truly deep, dark caves in some places, Oilbirds will roost and breed in narrow, semi-dark gorges and shallow grottos that have suitable rock shelves. One such well-known site is at Spring Hill near Arima, Trinidad, which is a water-worn tunnel with ledges only 3-4 m above a small stream. Similar places have been found at remote Venezuelan, Colombian and Ecuadorian sites with small Oilbird populations. An early suggestion that Oilbirds were associated with water is probably because most caves are found in karst, where water has hollowed out the rock, and usually there is some, or much, water still flowing through these caves.

Oilbird caves have been found in Colombia, Ecuador, Peru and Bolivia, as well as Venezuela, Trinidad and Guyana. However, individual Oilbirds have also been recorded from Brazil, Panama and the islands of Aruba and Tobago, and even as far north as central Costa Rica. Two things may account for this: first, Oilbirds fly far in a single night in search of fruiting trees; and, second, the national borders between Panama and Colombia, and those separating most South American countries are poorly explored, often rough mountainous areas, which may still harbour unknown caves.

In the most extensive caves, with large populations of thousands of birds, such as the cave at Caripe, Venezuela, the floor is covered with mounds 1-3 m high of seeds regurgitated by generations of Oilbirds. Many of these seeds germinate in the moist atmosphere, are blanched pale yellow and white, and die due to the lack of sunlight. These cave floors are alive with fauna such as spiders, cockroaches, whip scorpions, and cave crickets. Many caves, especially large ones, are also shared with thousands of bats.

Within caves, Oilbirds nest on the highest suitable ledges, often in remote sections, and sometimes as far as 770 m from an exterior opening. Since nestling Oilbirds have been harvested for centuries by indigenous peoples throughout their range, it is probable that the birds have retreated over time to the least accessible nesting and roosting areas (see Relationship with Man). Some caves, generally smaller ones, are used only for roosting and not for breeding.

General Habits

Extreme gregariousness influences all aspects of Oilbird life. The birds breed and roost closely together in gatherings of up to many thousands in suitably large caves, but also in groups of less than ten in small or marginally appropriate caves. There is great synchrony in Oilbirds' crepuscular departure from caves to nocturnal feeding grounds, and this is no doubt aided by vocalizations and perhaps by their unique echolocation clicks. At dusk there is often an hour of restlessness inside the cave when birds fly about calling and clicking, before large numbers leave the cave. Pairs, and associations of adjacently nesting pairs, return at the same time to feed nestlings several times nightly. Most other nocturnal birds feed independently on mammals and insects, but Oilbird associations are thought to be advantageous in finding and tracking ripe fruit of their preferred trees that are scattered over vast mountainous areas.

Oilbirds are strictly nocturnal, and spend the daylight hours hidden away in the depths of their dark caves. Due to the darkness, and also to the inaccessibility of most nesting and roosting sites, the birds' behaviour at the roost is rather poorly known, and these difficulties are accentuated by the fact that any human intrusion to one of the caves is almost certain to disturb the birds. As if these difficulties were not sufficient, the caves are often unhealthy sites for humans to spend much time in (see Relationship with Man).

There is an interesting case of parallel or convergent evolution between Oilbirds and some *Aerodramus* swiftlets, such as the famous edible-nest species. The two groups share no recent ancestry, and the swiftlets are confined to the Old World, occurring mainly in the Oriental Region. Both the Oilbird and the Edible-nest Swiftlet (*Aerodramus fuciphagus*), for example, nest and roost on ledges in caves, where they use echolocation for navigation (see page 399). Both species have other loud calls and screams, perhaps because there is natural loud noise in these environments such as running water or breaking ocean waves. In addition, Oilbirds and swiftlets hold their nests together with saliva, have protracted incubation and fledging periods (90-125 days for Oilbirds, up to 75-90 days for some swiftlets). Finally, the birds are highly social, and both have suffered long from persecution by man. Needless to say, much of this convergence may be ultimately attributable to their occupation of dark caves.

Voice

Any disturbance in an Oilbird cave causes a cacophony of nearly deafening shrieks, demonic screams and snarls, amplified by reverberations inside the cave, as the birds circle overhead. Humboldt called this noise "ear-splitting". These loud and intimidating vocalizations, representing a form of mobbing, are described by others as loud, harsh calls with a guttural quality and raucous screeches. A fast series of staccato sounds of many different frequencies and long sustained calls may make it easier for other birds to detect the position of calling individuals in total darkness.

The famous clicks of echolocation are used when Oilbirds fly in pitch darkness, to avoid collisions with other birds and with the walls of the cave itself. Echolocation clicks are actually sonar, because the bird judges from the echo how close it is to an object. The clicks sound like castanets, and are of a low frequency of about 7000 cycles/second, thus being audible to the human ear. Bats use echolocation to find flying food, but it is of much higher frequencies not audible to humans. The duration of Oilbird clicks is about 1 millisecond, and they are given in short bursts of 2-6 clicks repeated an average of 2-6 milliseconds apart. Experiments using adult Oilbirds flying in a totally dark room showed that they easily avoided hitting the walls and ceiling using echolocation, or when the room was lit and they could use their eyes. But in the dark, with their ears plugged they could not avoid collisions until their ears were unplugged again. Other experiments have shown that an object 20 cm in diameter is about the smallest that an Oilbird can detect by echolocation.

Outside their caves at night Oilbirds make shorter, less harsh "karr, karr" or "kuk, kuk" vocalizations, thought to be contact calls between individuals. D. Snow watched Oilbirds feeding at night, when two or three birds circled around each other with

The Oilbird is unique among birds in being a nocturnal frugivore. While in the darkness of its caves, it navigates by means of echolocation clicks, but once outside it apparently depends on sight and possibly smell in its search for fruiting trees.

Birds will travel surprisingly long distances, though when breeding they regularly return to feed their nestlings several times each night. The Oilbird's brown eyes often show up as bright red in flash lights.

low, clucking calls and a long, harsh "karrrr". He believed this group, and other evenly spaced trios of circling birds, might be involved in pair formation or courtship behaviour.

Chicks, while still in the egg, make high-pitched cheeps, and after hatching produce a variety of sounds, which become increasingly louder when they are begging. By the time they are well feathered, at about day 70, they utter harsh screams when alarmed, in the same way as the adults.

Food and Feeding

The Oilbird is an obligate frugivore. At night, when the birds emerge from caves they fly directly in search of fruiting trees. There, while hovering briefly, they tear fruits off the trees and swallow them whole. Nearly all of these fruits have single, usually large seeds. The muscular action of the Oilbird's stomach then strips the thin outer flesh (pericarp) from the seed, which is regurgitated intact, except in the case of figs (*Ficus*), an atypical food whose small seeds can be found in faeces.

The food of Oilbirds has been studied in Trinidad, Venezuela and Ecuador, and a total of 147,500 seeds from more than 80 species of tree have been identified. For these studies, the seeds, mostly 1-6 cm in diameter, were typically collected in wire baskets fastened underneath breeding ledges, or in Ecuador, by sampling the first 30 cm of the 2.5 m piles below nest ledges. This has afforded unusually good opportunities to identify the fruits fed to nestlings and also eaten by adult birds over the breeding season and, in Trinidad, throughout the year.

In Trinidad, D. Snow identified more than 36 species of fruit, and he found that Oilbirds fed mainly on three families: Arecaceae 52%, Burseraceae 25%, and Lauraceae 23%. In Venezuela, with a somewhat different climate, 40 species of fruit were found in the Oilbird's breeding-season diet, with proportions of Lauraceae 51%, Arecaceae 31%, and Burseraceae 7.6%. In undisturbed forests it is difficult to find flowering trees, which are often necessary for the identification of some difficult genera, so a few seeds in all studies remain unidentified.

Fruiting in many of these tropical trees is strongly seasonal, although in some species it varies from year to year, and at least one tree species used was found to be a biannual fruiting species. Generally laurel and incense trees produce abundant seasonal fruit crops, while the palms have smaller amounts of fruit but this tends to be available all year. Analysis of the most frequently selected fruits showed that the pericarp which is non-succulent is high in proteins and fat. Comparison of seeds dropped in differ-

ent Trinidad caves showed that the birds in one cave apparently exploited traditional feeding areas different from those used by the birds of other caves. Furthermore, individual birds may have special preferences. Seed collections from below active nests revealed that more tree species had ripe fruit during the months of maximum nestling feeding.

Except for palm fruits, Snow found that nearly all of the fruits that Oilbirds ate or fed to nestlings are spicy or aromatic when ripe, and a similar conclusion was also drawn by B. Tannenbaum and P. H. Wrege in their Venezuelan study. Interestingly, Snow found a species of odourless laurel fruit that was available at the same time as two other frequently eaten laurels. Analysis showed it was almost equally nutritious, but it was virtually absent from his seed collections. Thus, there is a strong case for the hypothesis that the birds find much ripe fruit by odour, which would tie in with the particularly well-developed olfactory organs (see Morphological Aspects).

The birds forage on canopy fruits from trees and palms that are 5-20 m high, though rarely they will also feed from the understorey. Groups of up to 20 or more birds circle or hover silently near a fruiting tree. Then with rapid, shallow wingbeats they fly into the foliage briefly, pluck and swallow fruits, and fly a short distance away, often returning subsequently to a different spot on the same tree. E. de Bellard noted that feeding Oilbirds settled in trees when clouds covered a bright moon, but began feeding again when the clouds had passed. Snow suggested that Oilbirds may also locate fruiting palms by sight because of the distinctive palm shape; their fruits are without noticeable odour.

At the large Caripe cave in Venezuela, R. L. Roca used radio-telemetry to follow ten adults, including birds of both sexes. Individual marked birds left the cave at the same time each night, along with hundreds of others. Although the colony as a whole appeared to forage at random each night close to the cave, single birds constantly chose to forage in the same directions and repeatedly in the same patches. The Oilbirds exploited discrete areas of primary forest and avoided disturbed forest. Most foraging was within a radius of 40 km of the cave but some birds flew as far as 150 km away in a single night.

Over time, one radio-tagged bird used a range of 85 km², while another used 96 km². One male was apparently a floater which visited the colony briefly several times then was absent from the radio signal area for periods of several weeks to two months. During the breeding season, April-July, the members of the Caripe colony together used about 300 km², but later their home range expanded to 1350 km², as fruit availability decreased. This wider area included the large area of primary forest at Mata

de Mango to the east, and still further away the extensive floodplain of the Orinoco Delta (see Status and Conservation).

Although the Trinidad birds used their caves all year, roosting in them after breeding, there was a marked post-breeding exodus from the Caripe cave. This same behaviour was postulated by B. K. Snow for the caves she investigated in Ecuador, where numbers of birds in the post-breeding period were dramatically lower than earlier in the season. These differences suggest that ripe fruit near some caves was not sufficient to support the birds following breeding, especially when fledglings increased the size of the local population.

All three of the principal Oilbird food families, and even two genera of laurels, plus three other families of fruit eaten occasionally by the extant Oilbird species, were found at the Green River Wyoming fossil site. S. L. Olson suggested that because early steatomithids "would have been effective disseminators of large angiosperm seeds, rapid co-evolution of both seed plants and their avian dispersal agents at the beginning of the Tertiary is likely".

Breeding

Everywhere that the Oilbird has been studied, it has been found to initiate breeding at the end of the dry season, although there is some variability from year to year probably due to differences in the timing and volume of rains. A typical breeding effort takes from four to more than five months, a considerable time, and this does not include post-fledging care, about which almost nothing is known.

Oilbirds appear to be monogamous on a long-term basis. Partners regularly roost together, and during breeding the off-duty bird typically perches close beside the nest, while courtship allopreening at the time of egg-laying may strengthen the pair-bond. All nesting responsibilities are shared, including nest building, incubation, brooding and the feeding of nestlings. This apparent long-term monogamy may be linked with a shortage of suitable nesting and roosting sites that appears to be the norm in most caves. Certainly some pairs repeatedly use the same nest over several years, and one ringed adult always returned to the same nest for at least 12 years.

Nests are situated on cave ledges and shelves close to the cave ceilings, sometimes 20-30 m high, though rarely as low as 4 m above the ground, and they are occasionally very deep inside caves. As pairs re-use the same nests each year, only a minor amount of reconditioning of the top nesting cup is required. These traditional nests are hard, truncated cones 20-45 cm high and 25-38 cm wide at the top. They are made of concentric layers of

regurgitated seeds, some excreta, and fruit pulp, all held together with the birds' saliva. Because the same nests are used again and again they gradually increase in height. At the top, a thin vertical rim of 2-3 cm surrounds the shallow nesting cup. In one case, F. Ortiz-Crespo described six nests in a very shallow cavity, set in a circle with the bases touching.

Some eggs are laid as early as March and as late as July in Trinidad, with the main period of egg-laying falling in April and early May; there, the clutch is of 2-4 eggs. In contrast, the main egg-laying months in Venezuela are May-June, and the clutch consists of 1-3 eggs. Eggs tend to be somewhat spherical, like some owl eggs. Ten eggs averaged 41.7 x 32.7 mm and the mean weight of ten Trinidad eggs was 20.2 g (17-22.5). Although the eggs are white they quickly become stained in the nest.

Egg-laying intervals are variable but long, at 2-9 days, and incubation begins with the laying of the first egg, so hatching is highly asynchronous, each egg hatching after 32-35 days. Some females incubate slightly more than males. As mentioned above, the non-incubating bird, when not foraging at night, remains perched alertly beside or even on the nest. Experiments showed that Oilbirds have a poor sense of egg retrieval if an egg is accidentally moved.

There is great synchrony of egg-laying within subsets of each colony, which is thought to facilitate the social foraging of off-duty birds. Pairs of birds with young return together to feed them, and at the same time neighbouring nesters also return to feed their young. During the 12-hour night very small young are fed 5-6 times, but larger young only 3-4 times.

As the diet of nestlings is entirely frugivorous, this results in slow and protracted development. Hatchlings weigh 12-16.5 g and, except for some sparse pale grey down on the underparts, they are entirely naked. At about three weeks old, they are covered in dense dark down. Also at about this time, nestlings begin to thermoregulate and are no longer brooded, and they also begin self-preening. A second generation of darker grey down pushes out the first down feathers, except for some of those on the underparts. Adult-style feathers begin erupting from sheaths on the tail, secondary coverts and scapulars by day 35, and at around ten weeks old the nestlings look similar to the adults, though they are about 50% heavier than the average adult weight of about 410 g. There is no juvenile plumage and nestlings never develop other juvenile visual signs even on the head or the bill, probably because they are raised in darkness.

Nestlings are fed entirely by regurgitation. Young birds squeal and call when an adult returns to the nest. Then the parent leans down with open bill and the chick places its bill inside. The two birds are often linked in violent struggles while fruit is transferred. Nestlings as young as 12 days old are fed whole undigested

Oilbirds almost invariably nest and roost in caves, though in places they will also utilize narrow, dark gorges. Nests tend to be placed on ledges high up the walls, preferably in remote sections of the cave, clearly with the aim of reducing the risk of predation. The nest is a truncated cone formed of regurgitated seeds and other waste products, cemented together with saliva; as the same nest is used year after year, it keeps growing taller.

[*Steatornis caripensis*, Asa Wright Nature Centre caves, Trinidad. Photo: M. D. England/Ardea]

Oilbirds are highly gregarious, roosting, nesting and feeding in the company of conspecifics, and their dense colonies are indeed noisy places, especially when disturbed by human intrusion.

As a result of their frugivorous diet, the chicks grow rather slowly and the nestling period is consequently long, but by the time they are about ten weeks old, they are much heavier than the adults. It is these deposits of fat, so attractive to humans for culinary reasons, that have given the bird its English and scientific names.

Marigo]

fruits and are able to regurgitate the seeds. Apart from these feeding bouts, the young are very lethargic in the nest.

Once a nestling is 1-2 months old, it receives nightly feedings equal to a quarter or a third of its body weight. Most fruit-eating birds eat large volumes, and the fruit is generally high in water and passes through the bird quickly, but the fruit fed to nestling Oilbirds is processed very slowly: plastic markers that researchers fed to nestlings averaged more than six hours in the birds' guts.

There is great variability in the development of nestlings of the same age, but at about 70-80 days they begin to lose their excess fat, while their plumage matures. At this same time the feeding rate decreases. Whether this slowing in the feeding rate is deliberate on the part of the adults, or a result of seasonal decrease in available fruits near the caves is not known; it may well turn out to vary from place to place.

The nestlings are brooded constantly for their first 25 days or so, at which point they are able to thermoregulate. D. Snow suggested that the extraordinary nestling fat aids the birds in thermoregulation when they are no longer brooded in dark and often wet caves, although the fact that the fat is concentrated on the chicks' ventral surface is perhaps something of an obstacle to this view.

Because of the asynchronous hatching, the growth of younger nestlings always lags behind that of their older siblings, and Tannenbaum and Wrege observed heavy brood reduction at the Caripe cave in a year of presumed fruit shortage. Oilbirds typically fledge at 100-115 (88-125) days old, after their weight has dropped close to the average adult weight and their wing feathers have attained adult length. A few ringed fledglings returned to their nests by day over a short time, but most were not found again in their natal caves.

Nearly 60% of the young that hatched in the Trinidad study reached the flying stage, so an average of a little more than 2 young were reared annually by each pair; at the Caripe cave 1.7 of the hatched young fledged. Some losses occur when eggs or young fall out of nests. In Trinidad, the crab *Pseudothelphusia garmani* was thought to be the cause of the death of some young nestlings. Venezuelan studies found that the spiny rat *Proechimys urichi* stole eggs and ate young, particularly those that fell to the cave floor. There, the highest, most inaccessible nest ledges suffered fewer losses. Predation by man at the time of maximum chick weight, for oil, appears to be the most widespread cause of nesting failure (see Relationship with Man).

The Trinidad study found that the birds renested following early loss, and that in a few cases second nests were made by early successful pairs. A few replacement nests were reported in Venezuela, but no second nestings, which perhaps corresponds with the smaller clutch there. It has been suggested that in Venezuela, and perhaps also in the Ecuador study area, the available ripe fruit within energetically economic flight range of breeding caves may limit the breeding season at those sites.

Movements

Although radio-tracking in Venezuela was used to monitor nocturnal behaviour of Oilbirds for seven months, it can not be used to track individual birds over longer time. Apparently, fledglings disperse from their caves of origin, and they are not philopatric in either Trinidad or Venezuela. Adults in Trinidad, however, continue to roost on their nests all year, where one ringed individual there was found to be faithful to the same nest for over 12 years. Nevertheless, at the Caripe cave in Venezuela there is usually a strong post-breeding departure to the Mata de Mango forest area east of the cave. In that area there are numerous smaller caves that are suitable for roosting, but apparently few that are adequate for breeding, and after the breeding season the forest there has more fruit (see Status and Conservation). The difference between these two tendencies may be that in Trinidad, at the time of the studies in the 1960's, there was a shortage of nesting sites in caves, and no feeding area was too far distant.

The massive post-breeding departure of an estimated 10,000 birds from the Caripe cave, leaving only a few hundred in the post-breeding months, may be a somewhat irregular occurrence. C. Bosque has suggested that such behaviour may be due to the loss of palms locally, as these should form one of the principal sources of food at that time of year. In other Venezuelan caves with breeding populations of over 1000 birds, however, the numbers roosting there in the post-breeding months falls to as low as only two birds. Similar behaviour has been suggested for caves in both Colombia and Ecuador, so post-breeding dispersal or nomadism may be of widespread occurrence in the Oilbird.

The home range of breeding Oilbirds has been estimated to be 85-95 km², with feeding localities as much as 150 km away. The remains of an Oilbird, thought possibly to have been an immature, and presumably killed by collision with a utility wire at

3100 m in Costa Rica, suggests that the species may be resident locally. However, the nearest known Oilbird cave is some 700 km away, by direct flight, in Colombia, as no Costa Rican or Panamanian Oilbird caves have been reported so far. The distance that Oilbirds disperse from known roosting caves remains mostly a matter of conjecture at the present time, and it is worth noting that one marked Oilbird in Venezuela flew 240 km in a single night to another cave.

Relationship with Man

In 1799 Humboldt and his companion, the botanist Amie Bonpland, were led by missionaries to the famous cave near the village of Caripe, Venezuela, to view the local ornithological sight: the impressive emergence at dusk of thousands of Oilbirds from this large cave. It was Humboldt who coined the name *Steatornis* from the Greek *stear* meaning "fat" or "tallow", and the English translation, Oilbird, has been used ever since. The village of Caripe is just six kilometres from the cave, and the source of the species name *caripensis*.

Far earlier, in 1678, a Capuchin monk, Fray Francisco de Tauste, described, in missionary documents, the dense clouds of birds that came out of the Caripe cave at night. He described the tasty oil that was made from squabs, and reported that the local Indians believed the souls of their dead went into this same cave. Oilbirds were then, and still are, called *Guácharos* in most of their native lands, a word said to come from archaic Spanish or possibly even Catalan meaning "crying, or making a loud lament". Throughout the species' range, fat nestling Oilbirds are, or have been, collected by indigenous inhabitants for their famous oil. The young are cooked to extract the oil which is reported to be odourless and clear, and to keep well. This oil is used mainly in cooking, but also in some places for lamp oil. There are reports of the use of adult and nestling Oilbirds for their meat, said to be palatable, even though the birds have a somewhat musky odour. Venezuelans have also used the stomach contents of Oilbirds in folk medicine.

Visitors to an Oilbird cave should take suitable precautions against histoplasmosis. This disease is caused by the airborne fungus *Histoplasma capsulatum* that, although widespread throughout the world, can cause in humans a reaction from mild to occasionally fatal, and can permanently damage the lungs or eyes of some individuals. The fungus, not known from the Oilbirds themselves, lives in highly nitrogen-enriched soils below large bird and bat roosts. When the dry soil is stirred by human activity or winds, the fungus is easily inhaled. Recent Oilbird researchers in Venezuela have all worn surgical masks at all times, as a precaution against this disease because the fungus is known to be especially widespread in Venezuelan caves; it is generally believed that wetter caves are less dangerous.

Status and Conservation

There are no figures on the world population of Oilbirds. The birds are easy enough to count at dusk when they are leaving small caves, but the large numbers that fly out together from such caves as Caripe, estimated by some researchers to be some 10,000 but by others only 5000, can not be counted accurately. Furthermore, counts are complicated by the recently discovered dispersal or nomadic behaviour of some South American populations.

Historically, suitable breeding and roosting caves have been the limiting resource for all Oilbird populations. Recent cave explorations in Venezuela have raised the total to as many as 54 caves used, or recently used, by Oilbirds. The discovery, in the mid-1980's, of several large Oilbird caves in the Venezuelan state of Bolívar on the border of Brazil may have doubled the estimated number of Oilbirds in Venezuela. In this mountainous *tepuí* area one cave, Aguapira, was reported to support as many as 10,000 Oilbirds. The combination of caves located in difficult forested terrain, and often on the poorly explored borders of South American countries, suggests that there may be more unknown populations of Oilbirds awaiting discovery.

While in most countries the Oilbird is protected by law, active nestling collecting was still being practised in Peru in the 1960's, and in Trinidad, Venezuela and Ecuador in the 1970's; in some remote areas it probably continues up to the present. Over time Oilbirds probably reacted by nesting on the highest and least accessible ledges and shelves in their caves. Even so, in Venezuela seven of 54 colonies, all in small caves, have been deserted, though this is apparently due to loss of foraging habitat close to large human populations; similarly, five of 13 caves in Trinidad have been abandoned by Oilbirds in recent years.

Humboldt recognized the problem of conservation when he learned of the massive raids on nestlings in the outer chambers of the Caripe cave. But he concluded that the annual harvest of thousands of nestlings was apparently sustainable due to reinforcements by birds breeding where the people could not reach the nestlings. There were, he said, Oilbird caves in the area with entrances too restricted for humans to enter, and also he heard Oilbirds in the Caripe cave far beyond the point where the native Indians refused to pass. In those days even the missionaries could not make the Indians go deep into the cave. The Indians believed the birds were ghosts of their ancestors, and to go far into the cave would be to enter the land of the dead. B. Snow, in her investigation of Oilbirds in the Los Tayos caves of Ecuador in 1976, again found human predation on nestlings, but she also believed that it too was sustainable because many of the nests were inaccessible.

In spite of the known and well-documented records of Oilbird predation by humans, it is the relentless attack on subtropical forests by the ever-increasing number of subsistence farmers in all range countries that pose the greatest long-term danger, as they threaten traditional Oilbird food resources. Tannenbaum and Wrege point out one fortuitous situation: many of the Lauraceae trees traditionally saved to shade coffee plantations are also those that are important in the Oilbird's diet. On the other hand, many of the palms that Oilbirds depend on during non-breeding months are selectively sought out and destroyed by man. An important *Euterpe* species is the source of the well-known edible Heart-of-palm, which is commercially canned and exported from Venezuela. Much of this product is gathered from palm trees in unregulated forests and the extraction of the heart kills the palm. Thus man's interests are in direct competition with the Oilbird's requirements. Few efforts are being made to cultivate the *Euterpe* palm for its heart, because it takes so long to grow to harvestable maturity.

Oilbirds, however, sow their own seeds. Roca's study of cast seeds in the Caripe cave suggested that most of the seeds covering the cave floor were regurgitated by nestlings. No seeds were found in collecting trays under nests that were being incubated, so adult birds were regurgitating the seeds, as many as 50 per bird per day, outside the cave before they returned. These he calculated to amount to about 21 t of seeds a month for this colony.

This fact formed the key to a major conservation action taken recently in Venezuela. Radio-telemetry had shown that through the year the birds of the Caripe cave spent much of their time foraging outside the protected area. Following the recommendations of Tannenbaum and Wrege, and also of Roca, the government in 1989 set aside an additional 66,400 ha area, the Mata de Mango, 15 km east of the already protected 15,500 ha Caripe cave area for the Oilbirds. Two other significant factors were involved: the Caripe cave and its Oilbirds are very well known throughout Venezuela, and a large tourist attraction; furthermore, by setting aside the new area as a National Park, it also protected the entire catchment area of the small Río San Juan which is currently important to both local agriculture and nearby commercial maritime petroleum transportation.

In Bolivia, Peru, Trinidad, and Colombia governments have set aside areas near and surrounding Oilbird caves, or are planning to do so. Protecting just the breeding or roosting caves will not succeed in saving the birds, because sizeable tracts of primary forest must also be included. In order for these plans to succeed, specific efforts will have to be made to overcome the usual problems of lack of money for personnel to enforce the national laws, and the lack of official will to oppose the small agricultural enterprises that constantly and permanently damage subtropical forests.

Family STEATORNITHIDAE (OILBIRD) SPECIES ACCOUNTS

PLATE 21

Genus *STEATORNIS* Humboldt, 1814

Oilbird

Steatornis caripensis

French: Guacharo des cavernes **German:** Fettschwalme **Spanish:** Guácharo
Other common names: Diablotin (Trinidad)

Taxonomy. *Steatornis caripensis* Humboldt, 1817, Caripe, Venezuela. Shows some owl-like features, but nowadays generally considered to be a caprimulgiform; regarded as an early offshoot within the order, probably closest to Nyctibiidae and Caprimulgidae. Monotypic.
Distribution. Panama and Colombia E to Venezuela, Trinidad, Guyana and N Brazil and S to Ecuador, Peru and Bolivia; also recorded in Costa Rica.

Descriptive notes. 40-49 cm; 350-485 g. Rich chestnut-brown all over with numerous white spots and diamonds edged with black; paler below with smaller white diamonds; large white spots on wings and outer rectrices; laterally compressed long hooked bill with stiff long vibrissae at triangular base; brown iris; long wings and a graduated tail held in inverted V; short, weak pink legs and toes. Fledglings as adults: no juvenile plumage. **VOICE.** Orientates within dark caves by means of echolocation clicks. Typical calls within caves are series of shrieks, screeches and screams; makes softer calls outside.

Habitat. Diurnal roosting and breeding takes place in caves and grottos, usually in mountainous areas of subtropical forests; locally occurs from sea-level up to over 3400 m. Forages in primary tropical and subtropical forests.

Food and Feeding. Feeds entirely on fruits: mainly of palms throughout the year, and aromatic Lauraceae, Burseraceae and others seasonally; fruit, 1-6 cm diameter, gathered only at night by small flocks hovering in flight and tearing whole fruits from high trees; only pericarp is used, with seed regurgitated undamaged; nestlings are fed on the same fruits. Nocturnal foraging distance up to 150 km.

Breeding. Attempt takes 4-5 months, starting at end of dry season: laying mainly Apr to early May (Mar-Jul) in Trinidad; mainly May-June in Venezuela. Monogamous, apparently on long-term ba-

sis. Nests colonially on shelves and ledges high up, usually in dark caves; nests are hard thick piles used in consecutive years, with a slight edged cup at top. Eggs 2-4 in Trinidad, 1-3 in Venezuela; rarely second nestings; both sexes co-operate in all nesting tasks; incubation 32-35 days; chicks hatch nearly naked, but are down-covered by 30 days; young are very slow-growing due to frugivorous diet; by day 70, nestlings are very fat and weigh 50% more than adults; loss of weight begins c. day 75 with concurrent growth of adult-like feathers; fledging near adult weight at c. 88-125 days; young generally do not return to natal cave, post-fledging care unknown. Age of sexual maturity unknown; one bird known to have lived over 12 years in the wild.

Movements. Post-breeding dispersal from continental South American caves; some nomadism particularly by juveniles. Other movements poorly known, but adults of Trinidad populations occupy same cave all year round. A group seen at Hillsborough Dam in 1988 was first record from Tobago, birds presumably having flown c. 30 km over sea from Trinidad.

Status and Conservation. Not globally threatened. Colonies have survived long history of predation by man of nestlings for fat in all range countries (see page 250). At present, most serious threat is loss of subtropical forests and their fruiting trees, to primitive slash-and-burn agriculture. No accurate figures of overall numbers available for whole of range. Easily the most accurate figures come from Venezuela, where 54 colonies have been located, and species is known from at least 19 more sites, but 7 of the colonies have been abandoned, seemingly due to loss of foraging habitat; main centres are in N Monagas (21 colonies, possibly supporting c. 20,000 birds) and S Bolívar (large colonies), followed by Falcón (c. 900-1400 birds) and Anzoátegui (500-800 birds), with smaller numbers elsewhere; largest colonies known are those at Aguapira (Bolívar) with c. 10,000 birds, followed by several in Monagas, notably Caripe (5000-10,000 birds), Cueva Grande (c. 5000 birds) and Cueva Clara (1000-2000 birds); total population of Venezuela may number c. 40,000-50,000 birds or rather more. Detailed information lacking for Colombia, but total numbers reckoned to be similar to or slightly lower than those for Venezuela; human disturbance judged to be more intensive in Colombian Andes. No information on status in S of range, where known colonies are widely scattered. In 1962, population of Trinidad estimated to number 1460 adult birds. Species not known to be kept in captivity.

Class AVES

Order CAPRIMULGIFORMES

Suborder CAPRIMULGI

Family AEGOTHELIDAE (OWLET-NIGHTJARS)

- Small to medium-sized nocturnal birds, with wide but rather weak bill, short legs and upright stance when perching.
- 18-30 cm.

- Australasia.
- Mainly forests or woodland, one species extending into open, dry scrubland.
- 1 genus, 9 species, 18 taxa.
- 1 species threatened; none extinct since 1600.

Systematics

Aegothelidae forms possibly the most distinctive subgroup within the Caprimulgiformes, and it is sometimes separated from the other families in its own suborder or superfamily. In the rather upright stance and the tendency towards a facial disc with eyes looking forwards, the owllet-nightjars show a certain similarity to owls (Strigiformes). A few anatomical characters shared by owls and owllet-nightjars, as well as the hole-nesting behaviour and unmarked white eggs common to both groups, suggest that these similarities may be at least partly due to affinity rather than to convergent evolution. Indeed, the DNA hybridization data obtained by C. G. Sibley and J. E. Ahlquist show the owls as the closest relatives of the Caprimulgiformes and the Aegothelidae as the most ancient surviving offshoot of the early caprimulgid stock, somewhat in conflict with the traditional view that the Oilbird (*Steatornis caripensis*) would occupy this position.

The two largest species, the Feline Owllet-nightjar (*Aegotheles insignis*) and the Moluccan Owllet-nightjar (*Aegotheles crinifrons*), were in the past sometimes separated from the other species in a separate genus, *Euaegotheles*, but this classification has been abandoned following the demonstration that supposed differences in their skeletal anatomy and in the size of the oil-gland do not really exist. All the living species are therefore now placed in the genus *Aegotheles*.

An extinct owllet-nightjar from New Zealand is known through numerous bones from deposits that extend up to the Holocene (the last 10,000 years). These were named as *Megaegotheles novaezealandiae*, the placement in a separate genus being based on the relatively long and strong legs shown by the fossils, which may have reflected more terrestrial activity than occurs in any of the living species of owllet-nightjar. It is now known, however, that the rare New Caledonian Owllet-nightjar (*Aegotheles savesi*) also has rather long legs, although these are less developed than in the New Zealand fossils, and this has resulted in the merging of the genus *Megaegotheles* into *Aegotheles*.

Another significant fossil of an owllet-nightjar is that named in 1977 as *Quipollornis koniberi* from the early to middle Miocene of eastern New South Wales, Australia. The single, partly associated skeleton differs from *Aegotheles* in proportions and in sufficient qualitative features as to leave little doubt of its generic distinctiveness. *Quipollornis* is valuable in showing that the Aegothelidae have a long history in the Australasian faunal region, which is the only region in which living

representatives of the family are known. Nevertheless, that discovery was eclipsed by the report in 1982 of a fossil aegothelid from the Phosphorites du Quercy in France, the deposits being older than those in New South Wales, and dating from the Upper Eocene to the Upper Oligocene. Along with a few finds of early Tertiary fossils of other caprimulgid families in the "wrong" continents, such as the spectacular records of frogmouths (Podargidae) and potoos (Nyctibiidae) in Europe, the Quercy aegothelid suggests that the early biogeographical history of the order was much more complicated than might be suggested by the ranges of its living taxa.

Several of the owllet-nightjar species are very poorly known and the genus appears rather uniform in most respects, so that it

As their English name implies, owllet-nightjars show characteristics somewhat intermediate between nightjars and owls. While the usual taxonomic treatment places them alongside the former, several anatomical features, along with their upright stance and hole-nesting habits, suggest an ancestral affinity with the latter. The legs and feet of the Australian Owllet-nightjar, in common with its congeners, are larger and stronger than in other Caprimulgiformes, perhaps as a result of a more terrestrial lifestyle.

[*Aegotheles cristatus*, Australia.
Photo: Len Robinson/FLPA]

The wings of owlet-nightjars are markedly rounded, an adaptation to their habitat and foraging behaviour. Although little is known about the feeding techniques employed by most species, the evidence suggests that they usually fly short distances in well-vegetated habitats, movements facilitated by paddle-shaped wings.

While this feature is conspicuous in the Australian Owlet-nightjar, its wings are in fact less rounded than those of its relatives while its tail is longer, presumably because it inhabits more open country. It also differs from most other members of the family in its less pronounced facial bristles, but resembles them in that its eyes are oriented forwards and set in facial discs.

is difficult to arrive at a sequence of species that reflects their evolutionary relationships. Despite these difficulties, two groups of species may be tentatively placed as the "least advanced" and the "most advanced" within the genus. The three large species, the Feline Owlet-nightjar, the Moluccan Owlet-nightjar and the Spangled Owlet-nightjar (*Aegotheles tatei*), show considerable superficial similarities to some Asian frogmouths (*Batrachostomus*), including a wide and rather strong bill; similar patterns of coloration, especially on the scapulars and underparts; predominantly rufous ground colour of plumage; parallel-edged and slightly pointed rectrices; and similar long semi-bristles over the ear-coverts. Hence, the size and other characters of those three species might be regarded as ancestral features in the genus, even though some of their similarities to frogmouths could be the result of convergent adaptations to similar lifestyles within rain-forest habitats.

The Australian Owlet-nightjar (*Aegotheles cristatus*) may be the most advanced species of the genus, with adaptations to life in open woodland habitat that include finely barred grey plumage; more pointed wings than in any congener; extensively frayed trailing edges to its remiges; a relatively long tail with broad feather tips; relatively large feet; black stripes on the crown; and somewhat shortened facial bristles. The Barred Owlet-nightjar (*Aegotheles bennettii*) shares many of the features of that species, while the New Caledonian Owlet-nightjar may be a more divergent member of the same group since it also has a predominantly barred pattern on its otherwise rather featureless dark plumage.

The remaining three species are tentatively placed between those least advanced and most advanced groups of species. Of the three, Wallace's Owlet-nightjar (*Aegotheles wallacii*) shows little evidence of close relationship to any congener, whereas Archbold's Owlet-nightjar (*Aegotheles archboldi*) and the Mountain Owlet-nightjar (*Aegotheles albertsi*) constitute an extremely similar pair of sibling species that apparently replace each other in different regions or mainly at different elevations in the mountains of New Guinea.

There are several uncertainties regarding the limits of species in this genus. Some of these difficulties arise because museum specimens are few, so that the problem of judging the taxonomic status of allopatric representatives, which is familiar in many other groups of birds, becomes harder to solve in the absence of specimens from zones of potential range contact. Moreover, lack of knowledge of the living birds, especially of their vocalizations, tends to increase the difficulties when attempting to make objective decisions about species limits in such cases as these.

Thus, with Wallace's Owlet-nightjar the well-marked subspecies *gigas* could well be treated as a distinct species, although another subspecies, *manni*, appears to be intermediate in some respects between *gigas* and the nominate form. A comparable problem exists in judging the status of the Vogelkop population, *affinis*, of the Barred Owlet-nightjar. It now seems clear that *affinis* does indeed belong with that species rather than with the Australian Owlet-nightjar, in which it was formerly placed by some authors, but it may be better regarded as a separate species; the absence of information on its voice makes it harder to decide the best treatment.

The very recent proposal to split the Spangled Owlet-nightjar as a distinct species from the Feline Owlet-nightjar is another instance of poorly known allopatric populations being of rather uncertain status, but in this case one form is montane and the other, the Spangled, is a lowland bird. Furthermore, recent studies by T. K. Pratt have demonstrated numerous hitherto unrecognized differences between the two in coloration and in details of structure, as well as providing additional specimens of the Spangled Owlet-nightjar, one of which extends its known range by over 1000 km eastwards from the type locality. The new information seems sufficient to tip the balance in favour of affording the Spangled Owlet-nightjar full species rank, although this treatment is not universally agreed upon.

Archbold's and the Mountain Owlet-nightjars present a different kind of problem in delimitation of species. They are so similar that some museum specimens cannot be confidently as-

One of the largest and most beautifully patterned members of the family, the Feline Owlet-nightjar, inhabits montane evergreen forests in New Guinea. This rufous morph individual shows the broad bill, open nostrils and conspicuous facial bristles characteristic of the family. While the function of these bristles is essentially unknown, they may help guide prey into the gape of foraging birds or serve as sensitive "whiskers" to help them navigate in dark nesting and roosting cavities. The widely spaced mandibles presumably assist in trapping mobile insect prey, either in flight or from surfaces such as trees or the ground. The difficulty of observing most owlet-nightjars is evinced by the fact that ecological data for this species, and several of its relatives, are almost entirely lacking. No nest or egg has ever been reported, and although its diet can be deduced from the gut contents of specimens, its foraging behaviour remains to be described.

signed to one or the other, a problem further aggravated by the wide variability in coloration of both of them. They are regarded as distinct species mainly because both have been collected at around 2062 m near the Wissel Lakes in Irian Jaya, where it seems that their altitudinal ranges meet, with Archbold's Owlet-nightjar occurring mainly at higher elevations and the Mountain Owlet-nightjar at lower elevations. Nevertheless, it remains a possibility that a single species exhibiting polymorphism in plumage coloration is really involved, with the different morphs mainly having different altitudinal ranges. Field studies in the Wissel Lakes region may shed light on this, especially if it can be demonstrated that the currently unknown voice of Archbold's differs from that of the Mountain Owlet-nightjar and thus serves as a species-isolating mechanism.

Variation between different populations within the Australian Owlet-nightjar is complex and unusual, resulting in a wide disparity in the numbers of subspecies recognized by different authors, with from two to eight forms bearing subspecies names in different accounts. This species' geographical variation in size is unusual in that the largest birds occur in the north of the range, in southern New Guinea, and the smallest in the south, with intermediates in the intervening area. This pattern is the opposite of that normally found, where the largest birds generally occur in colder regions, a phenomenon so widespread that it is known as Bergmann's Rule. Because the large New Guinea birds appear to be merely the end point of this clinal pattern of size variation, they are no longer afforded separate subspecific status. Variation in coloration of Australian Owlet-nightjar populations is also complicated, because in some regions the females occur as two colour morphs (with many intermediates), and there is much individual variability, too. As a rule, paler birds occur in the arid inland regions of northern and central Australia and darker birds in the more humid coastal districts of the south and east. Also, the rufous-morph females become more common in arid regions

of north-west Australia. Large series of specimens show, however, that much of this variation in coloration is clinal and intergrading, so the only subspecies now kept apart from the nominate form is the Tasmanian population, *tasmanicus*, which not only has dull, mainly sooty-grey plumage without any rufous tone but also has a disproportionately short tail.

Morphological Aspects

Structural features regarded as characteristics of the family include a wide but not especially strong bill; nostrils that are obvious and open, and placed near the tip of the bill; a desmognathous palate; the absence of basipterygoid processes; two carotid arteries; a sternum with two foramina (notches) on each side; no intestinal caeca (unlike all other Caprimulgiformes); pelvic muscle formula AXY; the absence of powder-down, but the presence of a large naked oil-gland; legs and feet larger and stronger than in most Caprimulgiformes; the number of phalanges in the outer toe not reduced; and the middle toe without pectination on its claw. Like the frogmouths, the owlet-nightjars have well-developed facial bristles, but as with that family their functions are largely unknown. It is tempting to suggest that the bristles may serve to direct prey into the gape during hunting, and perhaps act as tactile "whiskers" that help the birds in moving about and locating nestlings inside dark nest-holes, but detailed studies are needed to investigate such possibilities in a proper and methodical manner.

The wings of all owlet-nightjar species are more or less rounded, corresponding to feeding behaviour that mainly involves short sallying flights (see Food and Feeding). The Australian Owlet-nightjar has somewhat longer and more pointed wings than any of the other species and has a particularly long, full tail. This species commonly inhabits more open woodland than its conge-

The plumage of owlet-nightjars varies within species. Female Australian Owlet-nightjars, for example, are found in grey or rufous morphs, while males tend to be grey. Populations of arid regions are consistently paler or more rufous than those of moister regions, in apparent accordance with variations in soil colour. Adult plumage is coarsely barred with prominent pale facial markings while that of young birds, such as this one, is finely speckled and more uniform. In each case, patterns and colours effectively function as camouflage, helping the species to evade the attentions of predators.

The Mountain Owlet-nightjar usually frequents the understorey or middle storey of humid forest habitats in the New Guinea highlands. It has not been recorded below 800 m and ranges up to an impressive 3700 m, a truly montane distribution. It sometimes occurs at areas of forest edge, in gardens and in tree-fern savanna. Like other members of the family, it is generally secretive and nocturnal in habits, only seen by day when flushed from roosting sites. The bold white wing markings or modified remiges and rectrices so characteristic of many nightjars are absent in owlet-nightjars. The conclusion that intraspecific communication is conducted through vocal rather than visual signals is supported by the fact that no aggressive or courtship display has been recorded for any member of the family, except during nest defence.

ners, or even scrub in arid regions, so its structure may be related to feeding in more open situations.

The legs and feet are rather small and weak in most species of the genus, but slightly stronger in the Australian Owlet-nightjar than in most of the others. As already mentioned, the rare New Caledonian Owlet-nightjar has considerably longer, stronger legs and feet than the other species, while those of the extinct *Aegotheles novaezealandiae* of New Zealand were even better developed. Unfortunately, nothing is known of the lifestyle or former lifestyle of those two island endemics, although it has been inferred that they would be more active on the ground than other owlet-nightjars.

As with other families of the Caprimulgiformes, the coloration of owlet-nightjars consists of more or less sombre shades of brown, rufous, chestnut or grey, with or without a few bold markings of black or white. The two largest species, the Feline and the Moluccan Owlet-nightjars, have extensive areas of rufous to chestnut plumage, whereas the smaller species are mainly brown with a predominantly streaked pattern or grey to blackish with a predominantly barred pattern. In the Australian Owlet-nightjar, populations of the arid interior are commonly paler and more rufous than those of moister, better-wooded regions, whereas Tasmanian birds are very dark, each population apparently tending to match the prevailing colours of the soil. There can be little

doubt that the rather drab colours and the intricate patterns of streaking or barring exhibited by owlet-nightjars serve mainly to conceal them from predators. Where bolder signal markings are present they tend to be restricted to pale half-collars on the hindneck or bold patches on the scapulars, with none of the bold markings on the remiges or rectrices that characterize the true nightjars (Caprimulgidae). Very little information exists on the use of signal markings in communication by owlet-nightjars, but in any case it appears highly probable that much of their intraspecific signalling is by voice rather than by visual means.

Sexual dichromatism tends to be slight or absent, and the coloration of juveniles, where known, differs from that of adults mainly in having less well-defined markings, with pale half-collars and scapular spots weak or non-existent. Several species show well-marked variation in coloration, such that the extremes have been regarded as colour morphs, as for example in both sexes of the Feline, Archbold's and Mountain Owlet-nightjars and females of the Australian Owlet-nightjar. Confusingly, much of the literature on New Guinea birds refers to these morphs as "phases", a term which might more appropriately be reserved for age-dependent plumages. In any event, among these owlet-nightjars individuals showing intermediate coloration are common, so that it may be better to regard them as examples of very variable coloration rather than true polymorphism.

The Australian Owlet-nightjar often occurs in dry woodland dominated by Eucalyptus or Acacia trees. It is also found in many other environments including evergreen forest, mangroves, mallee scrub and shrubland, while some individuals even feed well away from trees in open grassland. In all habitats, this species occasionally perches at the entrance to roost- or nest-holes at twilight and occasionally in the middle of the day. While this behaviour might relate to birds warming themselves in sunlight, very little is known about its function. The birds usually only emerge if the roost tree is tapped or scraped, in response to which they normally fly directly into another roost-hole. Most territories have several available holes that may be used in rotation. The reluctance of the birds to perch in the open during daylight is unsurprising, given their vulnerability to predation and the fact that they are sometimes mobbed by passerine birds in mistake for owls.

Habitat

Most owl-nightjars are essentially forest birds, although the Australian occurs mainly in more open habitats and the habitats of the New Caledonian are not reliably known.

Of the seven forest species, four are primarily lowland birds, with maximum recorded elevations of 1800 m for the Moluccan, 1540 m for Wallace's, 1125 m for the Barred and 100 m for the rare Spangled. In the case of the poorly known Wallace's Owllet-nightjar, however, different races may have different altitudinal ranges, since the nominate form is known at 0-1125 m whereas the race *manni* is recorded only at about 985-1110 m. Besides inhabiting the forest interiors, the Moluccan and Barred Owllet-nightjars have been reported from forest edge and the Moluccan occasionally also in lightly wooded areas of cultivation and in coconut plantations.

The remaining three forest species are essentially montane birds, with recorded altitudinal ranges of 1150-3000 m for the Feline, 2062-3600 m for Archbold's and 800-3700 m for the Mountain. The altitudinal ranges of the sibling pair of Archbold's and Mountain Owllet-nightjars may show little or sometimes no overlap in regions where they both occur, such as in the Wissel Lakes area where both were found at 2062 m; the Mountain is found mainly at lower altitudes, with Archbold's mainly higher up. Besides their forest strongholds, all three of these montane species extend into other habitats, the Feline into forest edge, second growth and riverine woodland, the Mountain into forest edge, gardens and tree-fern savanna, and Archbold's probably into subalpine scrub in the highest parts of its range.

The Australian Owllet-nightjar shows several adaptations to more open woodland habitats (see Systematics, Morphological Aspects). This species sometimes occurs inside evergreen forest, among tall mangroves or in open forests dominated by eucalyptus (*Eucalyptus*), but it more typically occurs in open woodlands or tall scrub such as mallee. It also inhabits a wide range of open, low shrublands and it sometimes feeds away from trees in open grassland.

General Habits

Owlet-nightjars are secretive nocturnal birds that are infrequently seen during the daylight hours, and then only when they are acci-

dentally disturbed from roosting sites. Several species are so poorly known that even their roosting sites have remained undescribed, but it is known that the Feline, Mountain and Barred Owllet-nightjars often roost in tree holes and that these are the usual sites for the comparatively well-known Australian Owllet-nightjar. Other roosting sites described for the Feline Owllet-nightjar are in clusters of dead leaves or tangled vines, and for the Mountain Owllet-nightjar in dark tangles of shrubbery or bamboo and the hollow end of a broken-off tree fern, while a Barred Owllet-nightjar was once reported roosting on a branch. Sites used less frequently than tree holes by the Australian Owllet-nightjar are other types of hole or crevice, including crevices in cliffs or banks, hollows in termite mounds and inside roofs of derelict homesteads or abandoned nests of *Pomatostomus* babblers. Roosting Australian Owllet-nightjars are reported to remain alert, crouching with head erect, breast on the floor of the hollow and feet tucked up under the body.

There are several observations of owl-nightjars awake at the entrances to their roosting holes during the day, as well as a few reports of the Australian Owllet-nightjar "sunning" itself at the hole entrance on cold winter days. Details of the choice of roosting sites are available only for this species, which is known to use sites 2-8 m and occasionally 11 m above the ground and holes varying from shallow to 2 m deep. The same sites may be used year after year, although some territories contain as many as six roosting holes that may be used in rotation. If the roosting tree is tapped or scraped, the bird usually flies out quickly, often moving directly into another hole; sometimes, however, the bird peers from the entrance hole before disappearing back inside, clambering down tail first. Since owl-nightjars which perch in the open during daylight are commonly mobbed by honeyeaters (*Meliphagidae*) as if they were owls, and because they may be at risk from predators, it is perhaps not surprising that they are unwilling to stay in the open for very long during daylight.

Almost all activity occurs between dusk and dawn. In the Australian Owllet-nightjar there appear to be peaks of activity in the evening and for an hour before dawn, with a lull in the middle of the night. This species often drinks after dusk and towards dawn, flying down to squat at the edge of a pool of water.

Information on the pattern of social organization is available only for the Australian Owllet-nightjar, and even that species is poorly known for such a widespread and common bird. Although often appearing to be solitary, it is believed to pair for life, with

Nothing has been published about the diet or feeding behaviour of the Barred Owllet-nightjar. The scant information available suggests that owl-nightjars may employ a broad spectrum of techniques to collect their insect food. Although they usually sally from perches and are capable of plucking prey from hard surfaces without landing, they have also been observed feeding aerially, and eating ants without flying at all. The discovery of earthworms in some stomachs provides further evidence that a certain amount of terrestrial foraging takes place.

Ardea]

Although the Australian Owlet-nightjar usually nests in trees, its nest-holes have also been recorded in fence posts, fallen logs, man-made structures and riverbanks. The clutch, usually of 3-4 eggs, is incubated for around 25 days. When disturbed at the nest, adults or well-developed young often sit tight and may hiss at intruders as a threat display, revealing a large pink gape, while puffing out their feathers to increase their apparent size. Recent studies show that breeding adults, eggs and young are very vulnerable to mammalian predators.

the paired birds roosting in close proximity to each other throughout the year. The pairs are well spaced, apparently defending territories with areas of about 10-80 ha, although very few data are available. The churring call of this species presumably functions as territorial advertisement and defence, since the birds respond to playback of recordings by calling and sometimes by approaching. There is, however, almost no information on threat displays or other behaviour likely to be involved in defence of territories.

Knowledge of the comfort behaviour of the members of this family is extremely scant, although the Australian Owlet-nightjar is known sometimes to preen inside its roosting hollow and to head-scratch indirectly. Aggressive and courtship displays have not been described for most of the species, and much of their intraspecific communication is likely to be through vocalizations rather than posturing.

Voice

Vocalizations of the Spangled, Archbold's and New Caledonian Owlet-nightjars are undescribed and apparently unknown, and there are very few accounts of those of the Feline Owlet-nightjar. The reputation that several of these species have for being elusive and rare may well be lessened once their voices are described, as locating them will then be easier.

Only the Australian Owlet-nightjar can be regarded as well known vocally and it is remarkable that this species apparently has only four main types of call, far fewer than those species of frogmouth (*Podargus*) or typical nightjar (*Caprimulgus*) for which the vocabulary has been well described. By far the commonest call of Australian Owlet-nightjars is a rather high-pitched, grating, rattling "chirr-chiirrr", of two or three units. It is given throughout the year, by both sexes, normally from a perch, although calling in flight has been reported. There can be little doubt that the churring has the function of territorial advertisement, so that it could be referred to as "song". Louder, sharper and more abrupt versions of the churring call are sometimes ut-

tered by day from the roosting hole. The other vocalizations reported for the species are given only in special contexts: a high-pitched "yuk" by an adult calling fledging young from the nest; hissing by brooding birds giving threat display towards an intruder; and a low trilling by young begging for food, and perhaps also by adults when feeding young.

The call of the Barred Owlet-nightjar is described as a deep trill or a descending hollow "churr", which is apparently reminiscent of the commonest call of the Australian Owlet-nightjar, of which this species is regarded as a close relative. The Mountain Owlet-nightjar, however, has an entirely different call, described as three (sometimes two or four) downslurred whistles, each higher-pitched than the preceding one; an account of its giving an unpleasant-sounding, slowly delivered "whor whor-whor" may represent no more than another rendering of the same call.

The calls of the Moluccan Owlet-nightjar have recently been described for the first time and these, too, appear to be quite different from those of any congener. This species utters a wide variety of manic screams and cackles and responds to imitations of these. The most frequent call, apparently used in territorial advertisement, is a moderately weak, upslurred squeal or scream immediately followed by three short, unhurried screams on the same pitch. Others of the species may respond to that call with louder or more hurried versions of it. The alarm call is described as a series of wild, maniacal, blood-curdling screams and a cat-like yowling call.

Food and Feeding

The diets of the Spangled, Wallace's, Archbold's and Barred Owlet-nightjars are entirely unknown. For two more species the data on diet are very few, based on the unique type of the New Caledonian Owlet-nightjar having beetle remains in its stomach and on the gut contents of Feline Owlet-nightjars being recorded as insects, including beetles. Nothing has been reported of the feeding techniques for any of those species.

After being found in a felled tree, these Australian Owlet-nightjar chicks were hand-raised and successfully released. The darker plumage of the Tasmanian race *tasmanicus* is apparently already visible. In normal circumstances, nestlings acquire juvenile plumage after about 20 days and fledge around a week later. There is some evidence that they then continue to accompany their parents for several months, but further study is required to verify this.

[*Aegotheles cristatus tasmanicus*, Tasmania.

Rather little is known of the food and feeding of two other owlet-nightjar species. The Moluccan Owlet-nightjar takes small insects by sallying from perches in the middle storey of the forest, catching them in flight or by hover-gleaning from leaves. Studies using stomach-flushing of captured birds and faecal analyses show that Mountain Owlet-nightjars feed mainly on insects, mostly Coleoptera but with some Lepidoptera, Diptera and Orthoptera, but that they also take a few earthworms. Although this species forages at night beneath the forest canopy, its feeding techniques are unknown, so that the presence of earthworms in the diet provides useful evidence that some of its food is caught on the ground.

Information on diet and feeding techniques is more complete for the Australian Owlet-nightjar. This species feeds mainly by sallying from perches, capturing insects in its bill. Typically, it swoops onto prey from a low perch, taking insects from the ground or tree trunks, often without landing. It sometimes also picks up food, such as ants, while standing on the ground, or sallies upwards from the ground to take insects in flight. Occasionally, when insect prey is plentiful, it may feed mainly on the wing, making flights with rapid, regular wingbeats for up to about 30 m, mainly low over the ground. The diet recorded from gut contents of Australian Owlet-nightjars includes a wide variety of small insects and also spiders and millipedes. Most records are of beetles (Coleoptera), grasshoppers and their allies (Orthoptera) and ants (Hymenoptera), but other orders of insects recorded include Hemiptera, Dictyoptera (Blattodea), Lepidoptera (caterpillars and imagines) and Dermaptera. A record of seeds and vegetable debris in one stomach can presumably be attributed to the plant materials being ingested accidentally. Details of hunting behaviour and prey selection await accurate study, although it seems clear that prey are located and tracked visually and that individual insects are pursued.

Breeding

As with other aspects of the biology of owlet-nightjars, lack of information makes it difficult to generalize about their breeding.

Nests of six of the species, the Feline, Spangled, Moluccan, Wallace's, Archbold's and New Caledonian Owlet-nightjars, have not been described and are apparently unknown, while all that has been reported on the nesting of the Barred Owlet-nightjar are the measurements of its eggs and the fact that they are white and lack markings. Sparse information on the breeding seasons of several of these species has been derived from the sizes of gonads of collected specimens and the occasional record of a fledgling, but patterns remain unclear.

Two nests of the Mountain Owlet-nightjar have been described, both in hollows in dead tree stubs. In each case the nest contained a single white egg, but these may have been incomplete clutches.

The Australian Owlet-nightjar is the only member of the family for which breeding has been studied in detail. This species nests in holes, usually in trees, but occasionally in fence posts, fallen logs, crevices in derelict buildings or burrows in riverbanks. Nest-holes are generally 1-5 m above the ground, but occasionally at ground level or up to 20 m up, or, rarely, much higher. The nest, with an entrance 7-25 cm in diameter, is placed 0.3-3.5 m down inside the hollow, but in most cases no deeper than 1 m. Both sexes usually share in building a mound of fresh leaves or pieces of bark, on which the eggs are laid. The frequent use of fresh leaves of *Eucalyptus* or *Acacia* possibly suggests some benefit from insecticidal or insect-repellent properties of these leaves.

Laying occurs from August to December throughout the wide Australian range of the species. A report that it "may breed in any month, especially following rain in dry and arid regions" appears to be incorrect. Furthermore, and contrary to some reports, it appears that only a single brood is reared each year, although replacement clutches may be laid, sometimes in the same nest, if the first clutch is lost. The eggs are slightly glossy, rounded-oval to elliptical in shape, and have unusually thick shells. They are normally white; references to occasional clutches being marked with light spots or with pale brown presumably refer to soiled eggs. To date, eggs are known only for three species, the Mountain, Barred and Australian, and all fall within the range 27-32 x 21-25 mm. Clutches are usually of three or four eggs, rarely two or five, and eggs are laid at intervals of one or two

days. Incubation is carried out by the female, and perhaps also by the male, for a period of 25-27 days.

Hatching is spread over several days, confirming that effective incubation starts when the first egg is laid. The nestlings hatch covered in a white first down and are brooded day and night until their eyes open on the fourth or fifth day, and thereafter only by day until the grey second down emerges on about the 11th or 12th day. Only one adult normally broods, the other usually roosting by day in a tree-hollow nearby. If a brooding adult is disturbed at the nest, it generally sits tight and gives a threat display with the plumage puffed out, gaping to show the pink mouth, and hissing. The adults cease brooding entirely after about the 11th day, roosting close to the nest but not in the same hollow. Both parents then share in hunting for food and feeding the young, the feeding visits often lasting only for several seconds. As no nest sanitation is carried out after about the 11th day, droppings accumulate in the nest. Nestlings are fully feathered by about 14-17 days, but they remain in the nest for at least another seven days. During that period the adults hunt right through the night, feeding the young every 10-15 minutes throughout the first half of the night. Nestlings beg for food using a low trilling call, and adults are reported sometimes to respond with the same trilling sound when they are feeding their young. The nestling period is 21-29 days, rarely 32 days, although 35 days has been recorded in captivity.

The chicks fledge abruptly in the middle of the night, still with strands of down attached to their body plumage. Thereafter they apparently never return to the nest. It has been reported that juveniles remain with their parents for several months after fledging, but the duration and nature of post-fledging care need further study.

Movements

All species of Aegothelidae are believed to be sedentary, although some as yet undocumented dispersal of juvenile birds presumably occurs. The presence of Australian Owlet-nightjar populations on coastal islands such as Bathurst, Melville, Fraser and Kangaroo, as well as on Tasmania and in New Guinea, may suggest that some wandering or some dispersive movements have

at times been made by this species, but its populations are normally regarded as sedentary, whether in the arid Australian interior or in cold-winter regions of Tasmania and South Australia.

No instance of extralimital vagrancy has been reported for any member of this family, but the occurrence or former occurrence of taxa in the Moluccas, New Caledonia and New Zealand must presumably have resulted from past vagrancy, albeit perhaps at times when these landmasses were closer to Australia or New Guinea.

Relationship with Man

As retiring nocturnal birds that live mainly at low densities in forests, it is hardly surprising that owlet-nightjars infrequently come to man's notice, and even local tribespeople know little about them. Nevertheless, the Australian Owlet-nightjar became known to early European settlers under names that included Little Nightjar and Fairy, Little or Moth Owl.

Even the early ornithologists appear to have been less excited by their discovery than might be expected. The generic name *Aegotheles* given to these birds was merely a Greek version of "goatsucker", doubtless borrowed from its Latin equivalent of *Caprimulgus*, which was the familiar name for nightjars. For the modern ornithologist they remain one of the most challenging groups of birds: the Australian Owlet-nightjar must vie with few others for being the most poorly known bird that is common throughout Australia, while the nests, calls and behaviour of several of the Papuan species remain totally unknown. Modern techniques such as voice-recording and the use of playback to capture birds in mist-nets, radio-tracking and light-tagging, and the use of night-vision devices will surely allow a much fuller knowledge of them to be gained in the future.

Status and Conservation

Although known only from skeletal remains, the endemic owlet-nightjar of New Zealand, *Aegotheles novaezealandiae*, became extinct during the Holocene, and there is some circumstantial evidence that it survived until after the arrival of early Polynesians (Maoris) in New Zealand, only some 1000-800 years ago. Hence, its extinction may well be attributable directly or, more likely, indirectly to man's actions. The New Caledonian Owlet-nightjar was reliably known only from fossils and from the skin of a specimen collected in 1880, until the very exciting sighting of a single bird by J. Tobias and J. K. Ekstrom in November 1998. Contrary to the widespread trend for avian extinctions occurring on islands, the Moluccan Owlet-nightjar was recently reported to be common on Halmahera.

The lowland and montane forests of New Guinea support more species and subspecies of owlet-nightjar than any other region, and some of these are known only from a few specimens. Nevertheless, large areas in New Guinea have hardly been explored ornithologically and much forest remains, despite the encroachment of logging activity in some regions. It is likely therefore that improved ornithological knowledge, and particularly knowledge of owlet-nightjar calls, will reveal further populations of the scarcer forms.

The Australian Owlet-nightjar still remains one of the commonest and most widespread of nocturnal birds in Australia, although it is only sparsely distributed in Tasmania. This species' tolerance of varied types of woodland and scrub, even small patches in farmland regions, suggests that it is not currently at any great risk of decline, despite many road casualties and rather numerous losses due to introduced predators.

General Bibliography

Bock (1994), Brumfield *et al.* (1997), Burrell (1914), Cannell (1986), Cleere (1998), Glenny (1955), Hartert (1892, 1897), Mariaux & Braun (1996), McEvey (1985), Olson *et al.* (1987), Peters (1940a), Pratt & Pratt (1998), Rich & Scarlett (1977), Rose (1976), Scarlett (1968), Schönwetter (1964), Serventy (1985b), Sibley & Ahlquist (1990), Sibley & Monroe (1990), Sibley *et al.* (1988), Stettenheim (1974), Strahan (1994).

The Moluccan Owlet-nightjar is found at forest edge on Halmahera. Until recently, it was very poorly known, but recent reports have suggested it to be surprisingly common, occurring in at least one reserve and one proposed protected area. Its toleration of degraded habitats suggests that for the time being it may be reasonably secure. Although several members of the family are almost unknown in life, it is hoped that increased survey work within their ranges and improved knowledge of their vocalizations will result in further positive revisions of status.

rufous morph

Genus *AEGOTHELES* Vigors & Horsfield, 1826

1. Feline Owlet-nightjar

Aegotheles insignis

French: Grand Égothèle **German:** Käuzchenschwalm **Spanish:** Egotelo Grande
Other common names: Large/Reddish/Rufous Owlet-nightjar, Rufous Owlet-frogmouth

Taxonomy. *Aegotheles insignis* Salvadori, 1875, Hatam, Arfak Mountains, New Guinea. Perhaps forms superspecies with *A. crinifrons* and *A. tatei*; latter until recently treated as conspecific with present species, but studies suggest that it should be afforded specific rank (see page 253). Birds of SE New Guinea formerly separated in race *pulcher*. Monotypic.
Distribution. Mountains from Vogelkop to SE New Guinea.

Descriptive notes. 28-30 cm; 59-85 g. Probably the largest of the owlet-nightjars. Mainly brown or dark rufous, upperparts with few whitish spots or streaks and prominent lateral crown-stripes; throat white or buff, breast and belly boldly spotted whitish. Well-defined brown morph and rufous morph, connected by intermediates. Little information on juvenile; one described as being of rufous morph. **VOICE.** Little known, although rising series of slightly trilled "owrr" notes and single or repeated squeaky "kee" notes reported; a "foh... foh" call also described.

Habitat. Montane forest, especially primary forest and edges, but also reported from second growth and from riverine woodland in otherwise open country. Mainly 1150-2800 m, occasionally up to 3000 m.

Food and Feeding. Gut contents show that diet consists of insects, including beetles. Feeding behaviour has not been described.

Breeding. Season little known; birds in breeding condition collected Apr, May, Aug and Sept and a fledgling in Nov. Nest-site presumed to be a tree-hollow, but nest and eggs undescribed.

Movements. Presumed to be essentially sedentary.

Status and Conservation. Not globally threatened. Widespread and, where much forest habitat remains in the mountains of New Guinea, species can be at least locally frequent, e.g. frequently recorded in Tari Valley.

Bibliography. Andrew (1992), Beehler (1978), Beehler *et al.* (1986), Coates (1985), Coles (1995), Diamond, J.M. (1972, 1985), Eastwood (1989b), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Majnep & Bulmer (1977), Mayr (1941a), Mayr & Gilliard (1954), Mayr & Rand (1937), Peckover & Filewood (1976), Rand (1941, 1942b), Rand & Gilliard (1967), Ripley (1964a), Rowland (1995b), Sims (1956), Stresemann & Stresemann (1966).

2. Spangled Owlet-nightjar

Aegotheles tatei

French: Égothèle de Tate **German:** Tiefland-Käuzchenschwalm **Spanish:** Egotelo de Rand
Other common names: Rand's Owlet-nightjar

Taxonomy. *Aegotheles insignis tatei* Rand, 1941, low elevations at headwaters of Fly River, New Guinea.

Possibly forms a superspecies with *A. insignis* and *A. crinifrons*. Formerly treated as lowland race of *A. insignis*, but recent studies indicate that it is a separate species (see page 253). Monotypic.

Distribution. EC New Guinea at headwaters of R Fly and Amazon Bay.

Descriptive notes. c. 25 cm. Rather similar to montane *A. insignis*, but differs in notably smaller size, considerable reduction of white markings, especially on underparts and above eyes, and rufous-brown rather than blackish-brown underwing; tail pattern also differs; several other differences are rather less obvious. Juvenile plumage unknown. **VOICE.** Not described.

Habitat. Lowland forest.

Food and Feeding. No information.

Breeding. No information.

Movements. No information; presumed to be sedentary.

Status and Conservation. Not globally threatened. Known from only 4 specimens taken at 2 localities, so it is either a rare species or much overlooked. Extensive lowland forests remain in the regions from which it has been recorded, so the species is unlikely to be under any immediate threat.

Bibliography. Beehler *et al.* (1986), Coates (1985), Diamond, J.M. (1985), Pratt (1999), Pratt & Pratt (1998), Rand (1941), Rand & Gilliard (1967).

3. Moluccan Owlet-nightjar

Aegotheles crinifrons

French: Égothèle des Moluques **German:** Molukkenschwalm **Spanish:** Egotelo Moluqueo
Other common names: Halmahera/Long-whiskered/Painted Owlet-nightjar

Taxonomy. *Batrachostomus crinifrons* Bonaparte, 1850, no locality = Halmahera. Possibly forms a superspecies with *A. insignis* and *A. tatei*. Monotypic.

Distribution. Halmahera, Kasiruta and Bacan in N Moluccas.

Descriptive notes. c. 29 cm. Large owlet-nightjar. Upperparts finely vermiculated greyish-brown; underparts paler, variably spotted dark. Apparently has brown morph and rufous morph with intermediates, as in *A. insignis*; rufous morph less patterned, and more rufous above and on breast. Juvenile plumage unknown. **VOICE.** Recently described for first time. Wide variety of manic screams and cackles. Most frequent call, apparently used as territorial song, is a moderately weak, upslurred squal or scream immediately followed by 3 short unhurried screams on same pitch; other birds may respond with louder or more hurried versions. Alarm described as a series of wild, maniacal, blood-curdling screams and a cat-like yowling call.

Habitat. Lowland and hill forests; also tall secondary forests, forest edge and occasionally lightly wooded cultivation and coconut plantations. Recorded from sea-level up to 1800 m.

Food and Feeding. Small insects. Feeds by sallying for small aerial insects from perches in middle storey; also by hover-gleaning from leaves.

Breeding. No information available.

Movements. Presumably sedentary, but scanty information available.

Status and Conservation. Not globally threatened. Restricted-range species: present in Northern Maluku EBA. Known from few specimens. Little information, although species was found in 1994 on the site of the proposed Halmahera National Park, and was recently described as common on this island. Also known to occur at Mt Sibela, Bacan.

Bibliography. Andrew (1992), Bonham (1995), Coates & Bishop (1997), Lambert (1994), Lambert & Yong (1989), Olson *et al.* (1987), Stattersfield *et al.* (1998), Sujatnika *et al.* (1995), White & Bruce (1986).

4. Wallace's Owlet-nightjar

Aegotheles wallacii

French: Égothèle de Wallace **German:** Fleckenschwalm **Spanish:** Egotelo de Wallace
Other common names: White-spotted Owlet-nightjar

Taxonomy. *Aegotheles wallacii* G. R. Gray, 1859, Manokwari, New Guinea.

Probably not closely related to any congener. Race *gigas* has been proposed as a distinct species on basis of its considerably larger size and its montane rather than predominantly lowland range, but this treatment countered by the fact that *manni* is of intermediate size and occupies an intermediate altitudinal range; recent studies show that the three races differ significantly only in size. Three subspecies recognized.

Subspecies and Distribution.

A. w. wallacii G. R. Gray, 1859 - New Guinea in Vogelkop and along S side of Central Ranges E to Karimui; Aru Is.

A. w. gigas Rothschild, 1931 - Weyland Mts (W New Guinea).

A. w. manni Diamond, 1969 - N Coastal Range of New Guinea (Mt Menawa, Mt Turu).

Descriptive notes. 20-23 cm; 46.5-48.5 g (*wallacii*), 50.5-52 g (*manni*). Distinctive small owlet-nightjar. Nominate form is variable in plumage, but apparently without showing any well-defined polymorphism and with sexes generally similar. Dark brown above, with pale speckles and vermiculations; buffy-white to greyish-white below with dark spots or bars, breast mottled dark brown. Single apparent juvenile has crown all blackish-brown, marked only with fine irregular barring and speckling of buff, and heavily barred underparts. Races differ in size and sometimes in coloration; some *gigas* and *manni* have suggestion of white collar on hindneck. **VOICE.** Little information. Double whistle, first note rising, second falling and often with trill, may function as song; second note sometimes omitted.

Habitat. Forests, mainly hill and lower montane forests; occasionally enters gardens. Occurs from sea-level to 1540 m, but altitudinal range apparently varies with race; approximate range of nominate 0-1125 m, of *gigas* 1200-1540 m, of *manni* 985-1110 m.

Food and Feeding. Beetles reported. No other information.

Breeding. No reliable information available; published accounts of cream-coloured eggs with grey markings most unlikely to be based on those of an owlet-nightjar.

Movements. Presumably sedentary, but information scanty.

Status and Conservation. Not globally threatened. Apparently a rare, or perhaps elusive, species throughout its range, but unlikely to be immediately threatened since extensive forests remain within the ranges of all three of its subspecies.

Bibliography. Andrew (1992), Beehler & Finch (1985), Beehler *et al.* (1986), Coates (1985), Diamond (1969, 1972), Gregory (1995a, 1995b), Hartert *et al.* (1936), Mayr (1941a), Mayr & Meyer de Schauensee (1939b), Mayr & Rand (1936), Murray (1988), Olson *et al.* (1987), Pratt & Pratt (1998), Rand & Gilliard (1967), Rothschild (1931), Stein (1936).

5. Archbold's Owlet-nightjar

Aegotheles archboldi

French: Égothèle d'Archbold **German:** Archboldbergschwalm **Spanish:** Egotelo de Archbold
Other common names: Eastern Mountain Owlet-nightjar

Taxonomy. *Aegotheles albertisi archboldi* Rand, 1941, 2800 m altitude, 9 km north-east of Lake Habbema, New Guinea.

Formerly treated as a race of *A. albertisi*, but is apparently a sibling species, replacing it at higher elevations (see page 253). Monotypic.

Distribution. C New Guinea: known only from Wissel Lakes area, Nassau Range, N slope of Mt Wilhelm and Victor Emanuel Mts.

Descriptive notes. 18-20 cm; 29-35 g. Extremely similar to *A. albertisi*, from which even some well-made skins appear inseparable when series are compared under ideal conditions in a museum. Differs mainly in richer coloration of upperparts, with coarser dark barring and coarser white spots, and in underparts averaging darker, more richly coloured and more heavily marked; identification further complicated as both species have a rufous morph and a brown morph, connected by intermediates. Juvenile undescribed. Voice. Not described.

Habitat. Occupies montane forests, with reliable records at 2062-3600 m; reports from lower elevations may result from specimens being carried down from higher ground by native collectors. Probably lives in subalpine thickets at the upper limit of its range.

Food and Feeding. Unknown.

Breeding. No information.

Movements. Presumed to be sedentary, but information scanty.

Status and Conservation. Not globally threatened. Restricted-range species: present in Central Papuan EBA. Although species is known only from four small regions, it was apparently plentiful in some of them during the period from 1940's to 1960's, and extensive montane forests still remain there. Hence, the species is unlikely to be threatened, at least in the immediate future.

Bibliography. Andrew (1992), Beehler & Finch (1985), Beehler *et al.* (1986), Coates (1985), Diamond (1972), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Junge (1953), Mayr (1941a), Rand (1941, 1942b), Rand & Gilliard (1967), Ripley (1964a), Stattersfield *et al.* (1998), Sujatnika *et al.* (1995).

6. Mountain Owlet-nightjar

Aegothales albertisi

French: Égothèle montagnard

German: Bergschwalm

Spanish: Egotelo Montano

Taxonomy. *Aegothales albertisi* P. L. Slater, 1874, Hatam, Arfak Mountains, New Guinea.

Apparently a sibling species of *A. archboldi*, replacing it at lower elevations (see page 253). Three subspecies recognized.

Subspecies and Distribution.

A. a. albertisi P. L. Slater, 1874 - Arfak Mts of Vogelkop in NW New Guinea.

A. a. wondiwoi Mayr & Rand, 1936 - Mt Wondiwai in Wandammen Peninsula.

A. a. salvadorii Hartert, 1892 - locally from Weyland Mts to SE New Guinea.

Descriptive notes. 18-20 cm; 36-40 g. Variable, and can be virtually indistinguishable from *A. archboldi*. Likewise, has a rufous morph and a brown morph connected by intermediates; a "grey phase" sometimes mentioned in the literature refers to brown morph, which is not really greyish. Single juvenile skin, apparently of present species, is mainly dull rufous above, with some obscure dark barring, and lighter beneath with many streaks of dull buff and inconspicuous spots of blackish-brown. Race *salvadorii* generally duller in coloration, with fewer and smaller markings on upperparts and less distinct banding on

outer rectrices; race *wondiwoi* larger than the other two. Voice. Call consists of 3 mournful whistles, each of them downslurred or at constant pitch. Series of squeaky "kee-kee" notes also described.

Habitat. Mostly forests on mountains, extending to forest edges, gardens and tree-fern savanna.

Altitudinal range reported as 800-3700 m, although in the relatively well-known E Highlands it occurs at c. 1385-2615 m.

Food and Feeding. Gut contents of specimens and other data show that diet consists mainly of insects (mostly Coleoptera, also Lepidoptera, Diptera and Orthoptera) but also includes a few earthworms. Reported to forage for insects at night beneath the canopy and in clearings of montane forests, but details of feeding technique undescribed.

Breeding. Few data on season; birds in breeding condition in Jun and Sept, eggs in Aug and Nov, and a nestling in Apr or May. Only 2 nests have been described, in hollow dead tree stubs, once at forest edge and once in primary forest, the former c. 3-5 m above the ground. Each contained a single white egg. Incubation and fledging periods and shares of sexes in care of eggs and young unknown.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Race *salvadorii* is apparently common in at least parts of its range. The small numbers of specimens known for the other two subspecies may reflect the paucity of ornithological studies within their ranges rather than real rarity. Extensive montane forests still remain over much of this species' historical range, and no immediate threats are evident.

Bibliography. Andrew (1992), Beehler (1978), Beehler & Finch (1985), Beehler *et al.* (1986), Coates (1985), Coles (1995), Diamond, J.M. (1972, 1985), Junge (1953), Mayr (1941a), Mayr & Gilliard (1954), Mayr & Rand (1936, 1937), Olson *et al.* (1987), Rand (1941), Rand & Gilliard (1967), Ripley (1964a), Schulz (1988).

7. New Caledonian Owlet-nightjar

Aegothales savesi

French: Égothèle calédonien

Spanish: Egotelo de Nueva Caledonia

German: Schwarzückenschwalm

Taxonomy. *Aegothales savesi* E. L. and E. L. C. Layard, 1881, Tongué, near Nouméa, New Caledonia.

Affinities difficult to judge, but plumage pattern and broad tail feathers are at least suggestive that present species may be most closely related to *A. bennettii* and *A. cristatus*. Possibly intermediate between extinct *A. novaezealandiae* (see page 252) and other members of family. Monotypic.

Distribution. SW New Caledonia.

Descriptive notes. 28 cm. A rather nondescript, dark-plumaged species known from a single specimen, an adult male. Entire plumage, including wings and tail, brown with narrow greyish-white barring. Several published illustrations purporting to represent this species are based on *A. cristatus* and are therefore considerably inaccurate. Voice. Not described.

Habitat. Recent record of bird in humid riverine forest at altitude of c. 1000 m; this individual was judged to be foraging in subcanopy. Otherwise habitat apparently unknown; various comments in the literature are only speculation.

Food and Feeding. Label of type specimen states "Food Coleoptera", doubtless on the basis of its gut contents. Recent record of bird thought to be foraging: the bird flew about, disappearing intermittently, at which times it was presumed to be perching.

Breeding. No information.

Movements. No information, but presumed to be sedentary.

Status and Conservation. ENDANGERED. Restricted-range species: present in New Caledonia EBA. Until very recently, no definite records since 1880, when the only specimen was collected, and species was thought possibly extinct, although the paucity of ornithological work in New Caledonia still allowed hope that it might survive. A report of one being killed during 1960's by a hunter in the Païta region, not far from the type locality, has remained unconfirmed. However, in Nov 1998 a single bird was seen in the Ni-Kouakou Reserve, S New Caledonia; despite subsequent searches during 4-month study, no further sightings, suggesting species is probably rare.

8. Barred Owlet-nightjar

Aegothales bennettii

French: Égothèle de Bennett

German: Bennettschwalm

Spanish: Egotelo Barrado

Other common names: Bennett's/Collared Owlet-nightjar

Taxonomy. *Aegothales bennettii* Salvadori and D'Albertis, 1875, Hall Sound, south-east New Guinea. Regarded as conspecific with *A. cristatus* until the latter was discovered to occur in New Guinea within the range of present species, but the two are evidently close relatives. Race *affinis* has sometimes been suggested to be a race of *A. cristatus*, but its uniformly sooty coloration and rounded wings leave little doubt that it belongs instead with present species; nevertheless, recent studies suggest it may actually be better treated as a separate species. Five subspecies recognized.

Subspecies and Distribution.

A. b. affinis Salvadori, 1875 - Arfak Mts in Vogelkop Peninsula (NW New Guinea).

A. b. wiedenfeldi Laubmann, 1914 - N New Guinea from R Idenburg to Holnicote Bay.

A. b. terborghi Diamond, 1967 - Karimui Basin in E Highlands of Papua New Guinea.

A. b. bennettii Salvadori & D'Albertis, 1875 - S coast of SE New Guinea from R Koembe E to Milne Bay.

A. b. plumiferus E. P. Ramsay, 1883 - Fergusson I and Goodenough I (D'Entrecasteaux Archipelago).

Descriptive notes. 20-23 cm; 45-47 g. Sexes apparently similar, and there appears to be no polymorphic variation. Upperparts dark brown to blackish with narrow greyish-white vermiculations; broad pale buff eyebrows and whitish to buff hindneck-collar; underparts pale greyish to whitish-buff with broad spots and bars. A juvenile specimen has only a vague indication of the pale half-collar on hindneck. Races differ in both coloration and size; *terborghi* (known from a single specimen) apparently the most distinctive, being considerably larger than other forms and with darker, blackish upperparts. Voice. Call has been described as a deep trill or a descending, hollow "churr".

Habitat. Mainly lowland forests and their edges, normally up to c. 1000 m elevation, although the unique type of *terborghi* was collected at c. 1125 m.

Food and Feeding. No information available.

Breeding. Very little information. A recently fledged juvenile collected in Oct. Eggs are unmarked white, but nest-sites and clutch sizes seemingly not recorded.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Nominate race appears to be not uncommon, but there is very little recent information on the status of the other subspecies. Nevertheless, considerable areas of rain forest still exist in most regions of New Guinea, so none of the forms seems likely to be threatened.

Bibliography. Andrew (1992), Beehler (1978), Beehler & Finch (1985), Beehler *et al.* (1986), Coates (1985), Diamond (1967, 1972), Mathews (1927), Mayr (1937b, 1941a), Mayr & Rand (1935, 1936, 1937), Mees (1982b), Pratt & Pratt (1998), Rand (1942b), Rand & Gilliard (1967), Schodde & Mason (1981), Schönwetter (1964), Stresemann & Stresemann (1966).

9. Australian Owlet-nightjar

Aegothales cristatus

French: Égothèle d'Australie

German: Baumschwalm

Spanish: Egotelo Australiano

Other common names: Crested/Savanna Owlet-nightjar

Taxonomy. *Caprimulgus cristatus* Shaw *et al.*, 1790, New South Wales = Sydney area.

Apparently a close relative of *A. bennettii*, and formerly considered conspecific; *A. bennettii affinis* sometimes erroneously included within present species. Variation complex, but much of it clinal.

with largest birds in N of range; population in S New Guinea formerly treated as separate race, *major*, but appears to represent no more than end-point of size cline of nominate form; several other races listed in old literature are based on individual or polymorphic variation in coloration. Two subspecies currently recognized.

Subspecies and Distribution.

A. c. cristatus (Shaw *et al.*, 1790) - SE New Guinea between R Oriomo and Tarara (Port Moresby region); Australia.

A. c. tasmanicus Mathews, 1918 - Tasmania.

Descriptive notes. 21-25 cm; 35-65 g. Dark grey on upperparts, with pale spots and thin vermiculations; distinct pale eyebrows, rear crown-band and hindneck-collar; paler, often buff-coloured on underparts, with narrow brown vermiculations. Sexes frequently similar but female varies between a grey morph and a rufous morph, latter being particularly well marked in parts of N Australia, although intermediate birds are very common in some regions; extreme rufous morph apparently does not occur in male, although some males can be found with intermediate coloration. Juvenile resembles adult, but has slightly softer and sometimes more finely speckled plumage, shorter tail, somewhat shorter facial bristles, and pattern of black and whitish markings on crown and nape blurred or lacking. Race *tasmanicus* small, with disproportionately short tail, and upperparts rather uniformly dark sooty-grey. **VOICE.** Much the commonest call is a rather high-pitched, grating, rattling "chirr-chiirrr" of 2 or 3 units that doubtless serves to advertise territory. When disturbed, brooding adults may hiss while giving threat display.

Habitat. Open woodland, trees along watercourses, shrublands of *Eucalyptus* and *Acacia*, occurring especially in sclerophyll forests, tropical woodland and mallee; favours drier, more open, mature woodland and such taller shrublands as mallee; only occasionally recorded in tall mangroves, open grassland and rainforests. Sea-level to 1000 m.

Food and Feeding. Diet consists mainly of wide variety of small insects, with records of Dictyoptera (Blattodea), Coleoptera, Dermaptera, Hemiptera, Hymenoptera, Lepidoptera and Orthoptera; other invertebrates recorded are spiders and millipedes. Seeds and vegetable debris in the gut of a specimen may have been ingested accidentally. Feeds mainly by sallying from a perch to take insects and

other prey from the ground, from tree trunks or on the wing; when standing on ground, also picks up prey (e.g. ants) directly or flies up from ground to catch insects in flight.

Breeding. Season apparently the same throughout Australia, with eggs laid mostly Aug-Dec. Single-brooded; reports of second or third broods unconfirmed, although replacement clutches may follow loss of first. Sometimes makes no nest, but both sexes normally share in building mound of fresh leaves or pieces of bark; nests placed usually 1-5 m (0-20 m) above ground at bottom or end of vertical to horizontal hollow in tree or stump, rarely in fence post, fallen log, hole in building or burrow in riverbank. Clutch generally 3-4 eggs (2-5), white and unmarked, laid at intervals of 1-2 days; incubation by female, perhaps also by male, for 25-27 days; chicks hatch with dense, long and white first down, replaced after 7-10 days by long and grey second down, this in turn replaced by juvenile plumage a week or so before fledging; both parents brood and feed young, brooding continuously for first 4-5 days, then less constantly, all brooding and nest sanitation ceasing on c. 11th day; fledging 21-29 days (21-32); extent of post-fledging care needs confirmation, although it has been suggested that juveniles remain with their parents for several months after fledging.

Movements. Apparently sedentary throughout its range.

Status and Conservation. Not globally threatened. Widespread in Australia and moderately common over much of its range; sparser in Tasmania, where absent from some regions. Potentially at risk from competition for nest-holes with introduced Common Starlings (*Sturnus vulgaris*) in SE Australia and Tasmania, but there is no evidence of population decline. Recent study over five months in New South Wales has shown species to be rather vulnerable to mammalian predators, especially when it is nesting; of 7 radio-tagged adults, 4 were predated and 2 others disappeared in manner suggesting predation; of 6 nests studied, 4 failed to due to predation of adults, eggs or nestlings. Also suffers some mortality from domestic cats, from roadkills and perhaps from predation by goannas (*Varanus*). Nevertheless, the species seems able to withstand these pressures and to maintain its populations in settled regions.

Bibliography. Class AVES

Order CAPRIMULGIFORMES

Suborder CAPRIMULGI

Family PODARGIDAE (FROGMOUTHS)

- Small to large, stocky nocturnal birds with strong, wide bill, short legs, and upright stance when perched.
- 19-60 cm.

- Oriental and Australasian Regions.
- Mainly forest or woodland, several species extending into second growth, wooded savanna or dry scrub; mostly at low elevations, some species reaching 2250 m.
- 2 genera, 12 species, 25 taxa.
- No species threatened; none extinct since 1600.

Systematics

The allocation of the frogmouths (Podargidae) to the order Caprimulgiformes has been accepted by virtually all recent systematists, but the details of their evolutionary relationship to the other families in the order are much less certain. The taxonomic ranking of subdivisions within the frogmouths is perhaps even more controversial, while the sequence of species in the two constituent genera poses problems that have often been ignored for lack of reliable information.

The DNA-DNA hybridization data of C. G. Sibley and J. E. Ahlquist serve broadly to support the deduction from anatomical and other characters that the frogmouths are an early offshoot of caprimulgiform stock, well separated from the owls (Strigiformes), less remote from the true nightjars (Caprimulgidae) than are the owl-nightjars (Aegothelidae), but somewhat more remote from them than are the potoos (Nyctibiidae).

The two living genera of Podargidae are known only in the Australasian Region, where the genus *Podargus* is found, and in the Oriental or Indo-Malayan Region, home of the genus *Batrachostomus*. Great excitement has been generated, therefore, by the discovery in recent decades of fossil Podargidae in the early Tertiary of Europe. The fossils are from Eocene strata at Messel in Germany, and (*Quercypodargus olsoni*) from the Upper Eocene Phosphorites du Quercy in France. These fossil records confirm the impression of the antiquity of frogmouths that one gains from the anatomical and DNA data, but the fossils themselves are too fragmentary to shed much light on evolution within the frogmouths.

Until the DNA-DNA hybridization data were published, it was thought that the two extant genera were clearly distinct from each other, although still rather obviously members of the same family since they share a similar general appearance, as well as many structural characters and life-history traits. The DNA results, however, suggested that *Podargus* and *Batrachostomus* diverged long ago, leading Sibley and his collaborators to advocate recognition of a separate family, the Batrachostomidae, for the Asian frogmouths. Some avian taxonomists would nevertheless argue that, for the purposes of determining what the taxonomic ranking should be, the considerable similarities between the two genera should outweigh information on the timing of their divergence. Since such an approach is deemed rather subjective, however, it does not find favour with modern systematists.

Differences between the two genera in external structure and anatomy are not great, although some clear differences do appear to show through (see Morphological Aspects). Furthermore, the nests of the two genera are distinctly different (see Breeding). It may therefore be that the divergence of *Podargus* and *Batrachostomus* was more ancient than their external appearances and life histories would at first suggest, so that we should indeed separate them at a higher taxonomic rank than that of genus. While it is probably better, for the time being, to maintain the traditional arrangement within a single family, further biochemical, anatomical, life-history or paleontological studies may indeed produce overwhelming evidence that two families are really needed. Thus, in this climate of uncertainty, the best option at present may be a middle course, that of recognizing two subfamilies, Podarginae and Batrachostominae. This compromise has

Subdivision of the
Podargidae

[Figure: Tim Worfolk]

Structural differences between the two frogmouth genera are rather slight. Members of *Batrachostomus* are mostly fairly small, while all three *Podargus* are large, the Papuan Frogmouth being the largest of all. Also, in *Podargus* the bill is somewhat larger and broader, and the facial bristles generally less developed, while the tail appears rather more pointed, mainly due to the overshooting pointed central pair of rectrices. Plumage tends to be paler and more marbled, no doubt reflecting the somewhat different habitat preferences of the two genera.

[*Podargus papuensis*, Iron Range, Cape York Peninsula, Queensland, Australia.

Photo: Clifford and Dawn Frith]

In addition to their slight morphological differences, Oriental *Batrachostomus* and Australasian *Podargus* are clearly separated on distribution. Also, their nests are quite distinct, being much smaller and slighter in *Batrachostomus*, like this Philippine Frogmouth. Recent DNA results show that the two genera probably diverged longer ago than originally thought, leading some taxonomists even to advocate their placement in separate families. However, on present evidence it may be more appropriate to split them off in two subfamilies, emphasizing their notable divergence, but also their common ancestry.

[*Batrachostomus septimus*, Raja Sikatuna National Park, Bohol, Philippines. Photo: Bill Simpson]

the advantage of maintaining the unity of the two groups, while highlighting their divergence.

Among the Australasian *Podargus*, the Marbled Frogmouth (*Podargus ocellatus*) shows some resemblance to *Batrachostomus* in coloration. On the basis of these similarities, its rainforest habitats and its wide distribution, it has been suggested that this species retains more ancestral characters than the other two *Podargus*

species. On the other hand, the Tawny Frogmouth (*Podargus strigoides*) may be the most "advanced" species of its genus, being adapted to relatively open and dry, *Eucalyptus*-dominated woodland habitats in Australia, where it captures much of its food by swooping to the ground. Its predominantly grey coloration, rather long and pointed wings, short tail and strong feet have all been interpreted as adaptations to these dry woodland habitats. Thus, the Marbled Frogmouth is now listed first in the sequence of species in the genus and the Tawny Frogmouth last, contrary to the arrangement in the older literature.

In his classic review of *Batrachostomus*, published in 1937, E. Stresemann listed the species roughly in order of decreasing size, although he gave no reason for doing so. Nevertheless, this may approximate to an evolutionary sequence, since phylogenetic analysis suggests that ancestral *Batrachostomus* may have resembled *Podargus* in being large and in showing little or no sexual dichromatism. If this is correct, the Large Frogmouth (*Batrachostomus auritus*) and the Dulit Frogmouth (*Batrachostomus harterti*) may have changed least from the ancestral type, whereas small species with strong sexual dichromatism, such as Horsfield's Frogmouth (*Batrachostomus javensis*), have undergone the most significant evolutionary change.

Morphological Aspects

Among the structural characters that have been used to define the Podargidae, the very wide, strong bill is the most obvious feature and is the one which gives the birds their common English name. In its bulk and shape it is quite distinct from the rather weak bill with wide gape that characterizes most Caprimulgiformes. Associated with the shape and strength of the bill are a desmognathous palate, and nostrils forming narrow slits near the base of the bill, each of them protected by a membrane and hidden by feathers and bristles. The wide, strong bill enables frogmouths to cope with tough, hard-shelled prey (see Food and Feeding), but it is attached to a surprisingly flimsy skull, such that torchlight shining into the open mouth of a living bird renders the surrounds of the eyes and other parts of the skull partly translucent.

Deeper anatomical characters include absence of basiptyergoid processes, palatines that are broad throughout, 13 cervical

vertebrae, a sternum with two pairs of posterior notches, and the presence of a single carotid artery, the left one. The wings are rounded, with the fifth, sixth or seventh primary the longest. The legs are very short, the tarsus being shorter than the middle toe, and both legs and feet are rather weak. Unlike the case of the Caprimulgidae, the number of bones, or phalanges, in the outer toe is not reduced, and the claw on the middle toe is not pectinated as it is in the true nightjars. Large patches of powder-down feathers are present on each side of the rump. The older literature stated that the frogmouth family lacks an oil-gland, but it has been established that this is true only of *Podargus* and that an oil-gland is present in *Batrachostomus*. The tongue of *Podargus* has a long, translucent, paper-like tip and was described as "certainly one of the most curious found in the Class of Birds", but the tongue of *Batrachostomus* has apparently not been described in detail. The arrangement of feathers (pterylosis) of *Podargus* has also been described as showing important peculiarities, but again there are no comparative details on feather-tract characteristics of *Batrachostomus*.

Structural differences between the Australasian *Podargus* and the Oriental *Batrachostomus* are not great, although members of the former are for the most part larger than those of the latter, the exception being that some Large Frogmouths overlap in size with the smallest individuals of *Podargus*, while the small species of *Batrachostomus* have no parallel in *Podargus*. Also, as already noted, an oil-gland is present in *Batrachostomus* but not in *Podargus*. A further difference between the two genera is that the central rectrices of *Podargus* are clearly longer than the next pair and have pointed tips, whereas *Batrachostomus* has the central pair only slightly longer than the others, with rounded tips. The extraordinarily wide bill is proportionately longer in *Podargus* than it is in *Batrachostomus*.

Facial bristles are well developed in all *Batrachostomus* species, but less so in *Podargus*. The "auricular plumes" of *Batrachostomus* consist of slender semi-bristles that are black or dark-coloured and long, often extending over the ear-coverts. However, the development of bristles on the front of the face and of auricular plumes varies somewhat among species, and even among subspecies in the Philippine Frogmouth (*Batrachostomus septimus*). As examples, the Sri Lanka Frogmouth (*Batrachostomus moniliger*) has relatively short facial bristles, whereas in

the Short-tailed Frogmouth (*Batrachostomus poliolophus*) they are particularly well developed, reaching lengths of up to 2.5 cm on the forehead and about 4 cm over the ear-coverts in the subspecies *mixtus*. The function of these bristles and semi-bristles is virtually unknown, and may vary according to their position on the head. It is tempting to regard long rictal bristles as helping to direct prey into the mouth and perhaps serving a tactile function, whereas auricular plumes may assist in shedding rain water.

The short legs of frogmouths reflect their arboreal habits and a lifestyle in which walking is usually restricted to a few shuffling steps along a branch, or, in some species at least, along the ground after they swoop down onto insect prey. In *Batrachostomus* the tarsi are partly feathered, but sex differences that have been reported in the extent of feathering apparently do not really exist. The postures of frogmouths when perching are typically more upright than those of nightjars, and the freezing, concealment postures sometimes adopted by most, if not all, species are often still more erect. The rounded wings correspond to feeding behaviour based on short sallying flights to pick prey from the ground, trunks or foliage, and at least two species even break off twigs for use as nest material while in flight. The wings are most conspicuously rounded in those *Batrachostomus* species that spend much of their lives in such dense vegetation as bamboo thickets or the dense understorey of lowland rainforest. The Tawny Frogmouth typically occurs in much more open habitats and hunts over open spaces, so it is not surprising that it has proportionately longer and more pointed wings, which presumably confer more rapid flight but with some loss of manoeuvrability. The flight of this species, however, is described as noiseless, like that of several other frogmouths.

As is normal among the Caprimulgiformes, the plumage coloration is mainly of rather sombre shades of chestnut, rufous, brown or greyish, although many species have beautifully intricate patterning. These drab tones are doubtless related to an overriding need for the birds to be concealed from predators, especially during the day, when they are roosting, but perhaps also at night, when owls may pose a threat. Any brighter signal markings usually consist of white spots or patches, occurring on the upper mantle as a half-collar, on the wing-coverts or on the scapulars, but these are of limited extent and are entirely absent in some species and absent from the juvenile plumages of others. The difficulties inherent in observing and studying nocturnal birds such as these probably account for the lack of published information on the usage of these signal markings, but many of the species may in any case rely more on vocalizations than on visual cues for communication.

At first sight, the colour and pattern of the plumage appear rather different in the two genera. Heavily streaked and elaborately vermiculated greys and browns predominate in *Podargus*, whereas many *Batrachostomus* species appear more uniformly rufous, although some, especially males, are heavily streaked. The pattern and coloration of *Podargus* may be related to the fact that two of the three species occur in relatively open habitats with many grey-barked trees, whereas most *Batrachostomus* are birds of dark, wet forest. The third *Podargus*, the Marbled Frogmouth, is a bird of lowland rainforest, and it shows the greatest similarities in coloration to *Batrachostomus*. This is especially true of females of the race *inexpectatus*, from the Solomon Islands: their plumage coloration is remarkably reminiscent of that of the Large Frogmouth of South-east Asia, although lacking the white hindneck-collar of the latter.

It is noteworthy that, where sexual dichromatism occurs, in both genera, the females tend to have slightly to considerably more rufous, or browner, coloration and less marked patterns of light and dark colouring. This is presumably related to the fact that, so far as is known for both genera, it is the males rather than the females that incubate during the day, suggesting that the need for cryptic plumage for predator avoidance is greater in males than in females.

Collectors preparing skins often make mistakes in determining the sex of bird specimens. This, together with the tendency for the females of some *Batrachostomus* species to look brighter than their males, has led to a number of errors or muddles in the literature over which sex has which type of plumage. With sev-

Horsfield's Frogmouth is shrouded in a good deal of taxonomic confusion. It has at times been considered conspecific with either or both of the Sunda (Batrachostomus cornutus) and Hodgson's Frogmouths (B. hodgsoni), and its two northern races have often been treated as forming a separate species, Blyth's Frogmouth (B. affinis). Even at the subspecific level there are problems: in central peninsular Thailand, where northern continentalis meets southern affinis, an intermediate population can be found. Birds on Palawan, too, are sometimes treated as a distinct race or even species.

[*Batrachostomus javensis*, Khao Noi Chuchi Non-hunting Area, southern Thailand.
Photo: Pete Morris]

Once located in the field, frequently no mean feat, a frogmouth can usually be easily identified as such, though it can be quite a challenge to determine the correct species or sex.

Frogmouths are restricted to the Oriental and Australasian Regions, whereas the potoos, to which they bear a superficial resemblance, are Neotropical birds.

All frogmouths are characterized by a big head and a massive, very slightly hooked bill of extraordinary width, strong enough to allow them to capture and swallow larger, tougher prey than nightjars. Both genera sport tufts of facial bristles, which spring mainly from the forehead but also from the ear-coverts. Despite various tentative suggestions as to their utility, their true functions remain a puzzle.

By means of subtle natural colours and much streaking and mottling the soft plumage of frogmouths affords great protection from danger as they are able to "melt" into their surroundings.

The species are variously patterned often according to the type of tree they roost in: the white blotching on the wing-coverts of this Tawny Frogmouth imitates to perfection the flaky nature of the tree bark and the lichens. When danger threatens, or the bird feels itself to be observed, it will adopt a "freezing" alarm posture by assuming a more upright stance, raising the bill and head skywards, and closing the eyes to mere slits, while a stump-like immobility completes the camouflage.

[*Podargus strigoides phalaenoides*, Cape York Peninsula, northern Queensland.
Photo: Clifford and Dawn Frith]

Frogmouths are highly sedentary birds, and have rather rounded wings, a short tail and weak legs and feet. Nevertheless, they can in fact fly strongly. Hunting at night from a branch, a bird will swoop down with silent flight on bowed wings to seize prey in its wide gape. The feet are not adapted for pouncing, and are used mainly for perching, though a bird may walk along a branch or, more briefly, on the ground, in search of food. The Tawny Frogmouth has longer and more pointed wings than most other frogmouths, reflecting its use of more open areas.

[*Podargus strigoides strigoides*, Lamington National Park, south-east Queensland. Photo: Glen Threlfo/Auscape]

eral of the species, matters have been complicated even further, because both sexes show polymorphic variation in coloration. For those species for which plenty of specimens are available, it now seems reasonably sure that the plumage types of each sex are properly understood, as for example with Gould's Frogmouth (*Batrachostomus stellatus*); but for others, such as the scarcer races of the Philippine Frogmouth, there are still doubts. Evidence of this may be offered by the recent describing of a new species of frogmouth, "*Batrachostomus pygmaeus*", from Busuanga Island, Palawan, in the Philippines. There seems to be a good chance that the single specimen upon which the description was based may actually have been an extreme or aberrant example of the race *affinis* of Hodgson's Frogmouth (*Batrachostomus hodgsoni*), which is resident on Palawan. Correctly sexed juvenile specimens are so few in collections that there is much uncertainty about the juvenile plumage of each sex for several of the *Batrachostomus* species.

Some statements in the literature rather confusingly refer to colour morphs as "phases", but the latter term is perhaps better avoided in this context, as more precisely referring to age-dependent plumages. When plumage variation due to subspecies, sex and age is taken into account, three species are found to show well-marked polymorphism in coloration: Gould's Frogmouth has chestnut-morph and dark-morph adults, apparently without intermediates; the Philippine Frogmouth has a chestnut morph, a mottled morph and intermediate individuals; and males of the Sunda Frogmouth (*Batrachostomus cornutus*) have a black-and-white morph and a brown-and-buff morph, along with intermediates. Despite the presence of intermediate birds, it seems better to describe the colour forms of these last two species as morphs, because they are very distinct visually.

Habitat

Most species of frogmouth are forest birds, but one has become wholly adapted to more open habitats with trees, and some of the characteristic forest species extend into other types of woodland.

The restriction to forest habitats is especially strong in the nine species of the genus *Batrachostomus*, with evergreen primary forest being the typical habitat of all but one of them. The

exception is the Sunda Frogmouth, which occurs mainly in second-growth forest and at forest edge, sometimes in plantations. Of the other eight species, however, the Large, Gould's, the Sri Lanka and perhaps also Horsfield's Frogmouths have been reported to occur sometimes in second growth, while the first of these also lives in swamp-forest, and the Sri Lanka Frogmouth extends into varied evergreen woodland and bamboo thickets. Perhaps the most remarkable extension of habitat preferences is

Over the years there has been a great deal of confusion in relation to frogmouth plumages, further complicated by the marked individual variation in colouring in most species and also by the presence of different colour morphs in some. Sexual dimorphism is quite noticeable in some taxa. Posing conveniently on the same branch to facilitate comparison, this pair of Marbled Frogmouths of the rare race *plumiferus* can be sexed by plumage differences: the female shows a plainer pattern and buffier coloration over all her underparts.

[*Podargus ocellatus plumiferus*, Gwongorella National Park, south-east Queensland. Photo: Marco Sacchi]

A little-known species, the Large Frogmouth is indeed the largest of its genus, overlapping in size with some of the smallest Podargus. It has a wide distribution in South-east Asia, though it is everywhere uncommon. Like all but one of its congeners, it is a true rainforest bird, frequenting the interior of primary lowland evergreen forests, though sometimes occurring in tall secondary growth, especially where a wealth of dense tangled vegetation offers plenty of cover in the middle and upper storeys.

[*Batrachostomus auritus*,

Park, West Kalimantan,
Borneo.
Photo: Tim Laman]

shown by Horsfield's Frogmouth in Thailand, where the species occurs locally in mixed deciduous forest, including that on limestone crags. Unfortunately, it is not yet known whether or not it moves out of these deciduous habitats when the trees become bare of leaves.

The genus *Batrachostomus* includes lowland species and others of sub-montane areas. Among those inhabiting lowland forest are Gould's and Horsfield's Frogmouths, the former found only up to 500 m and the latter typically to 1600 m. The three sub-montane species are Hodgson's, Dulit and Short-tailed Frogmouths, the last of which occurs at 600-2540 m. One, the Philippine Frogmouth, has a wide altitudinal range, being found from sea-level up to 2500 m. Separation of some of the species of this genus at different altitudes might have resulted from competitive interactions, whereas the very wide altitudinal range of the Philippine Frogmouth may reflect the absence of congeners on the islands it inhabits.

Such ecological isolation in *Batrachostomus* through altitude, and also through habitat and body size, seems particularly clear in Borneo, which is the richest region for the genus, harbouring a total of six species. Two of them, one large and the other rather small, are sub-montane, and the other four are lowland birds. Of those four, the Sunda Frogmouth prefers second growth while the other three prefer primary rainforest; the three range in size from the Large Frogmouth, at about 206 g, to the tiny subspecies *affinis* of Horsfield's Frogmouth, weighing about 46.7 g, so size differences may prevent much competition among them. The considerable disparity between some of the species in relative length of the tail may be related to differences in hunting behaviour, and hence also serve to reduce interspecific competition.

In Australia, the three species of *Podargus* appear to be for the most part separated by their habitat preferences. The Marbled Frogmouth lives mainly inside evergreen forest, while the Papuan Frogmouth (*Podargus papuensis*) is found along forest edges; the Tawny Frogmouth inhabits a variety of drier types of woodland, many of them dominated by *Eucalyptus* species, as well as occurring in some types of scrub and in groves of trees in more open country. The large size of the Papuan Frogmouth may also serve to reduce competition where it meets the other two species.

The Tawny Frogmouth is absent or, at best, extremely rare and local in New Guinea, and there is some evidence that the

Papuan Frogmouth extends into more open habitats there, including groves of trees in savanna, than it does in Australia, providing a possible example of "adaptive release". Similarly, in the case of the Marbled Frogmouth, the smaller size of the races *ocellatus* in New Guinea and *plumiferus* in north Australia, which are sympatric with large-bodied congeners, compared with those that are not sympatric with congeners, namely *intermedius* in the Trobriand and D'Entrecasteaux Islands, *meeki* on Tagula Island (Louisiade Archipelago) and *inexpectatus* in the Solomons, may be indicative of "character divergence" related to presence or absence of interspecific competition.

All three *Podargus* species show a good degree of habitat tolerance. The Marbled Frogmouth occurs from sea-level up to 1500 m in New Guinea, and extends from its lowland rainforest strongholds into tall secondary forest and monsoon scrub, while there are a few Australian records of it in 20-year-old monocultures of *Araucaria*. The Papuan Frogmouth in New Guinea is found from sea-level to 1000 m, rarely ascending to 2250 m, and, besides the forest-edge and savanna habitats already mentioned, it ranges into second growth and urban gardens with trees. The wide habitat tolerance of the Tawny Frogmouth in Australia has already been noted, and its adaptability in colonizing urban gardens with trees is well known. It can also extend into rainforest regions where roads provide corridors of the open habitat it needs for hunting, bringing it alongside Papuan Frogmouths, but it does not commonly penetrate far into the rainforest interior that is occupied by Marbled Frogmouths.

General Habits

Frogmouths are secretive, nocturnal birds, and many of the species spend their entire lives in the understorey of dense forest, so it is hardly surprising that little is known of their habits. The best information is for the Tawny Frogmouth, which commonly lives in more open situations than all of the other members of the family, although even this species lacks any really thorough studies involving marked birds. The two other Australasian frogmouths, the Papuan and the Marbled, are considerably less well understood. In comparison with all the Australasian taxa, however, the

Frogmouths are masters of camouflage, as seen in this statuesque family group of Tawny Frogmouths. When alarmed, birds freeze into set positions so as to "become" ragged stumps of broken branches, their facial tufts aiding to break up the silhouette. Once the threat is over, the birds relax and assume less tense and upright stances. Tawny Frogmouths use a number of different daytime roost-sites, normally on branches, often in quite exposed positions. Though habitually alone or pairs, groups of up to five birds may roost communally, even side by side on the same branch, thereby taxing their powers of camouflage to the maximum.

[*Podargus strigoides strigoides*, Whyalla, South Australia. Photo: Barry Silkstone/Nature Focus]

Asian *Batrachostomus* species are even more poorly known in life; most information is available for the Sri Lanka and Hodgson's Frogmouths, with scraps of data on several of the others, but nothing at all is recorded of the Dulit Frogmouth in the wild. This incompleteness of our knowledge must be borne in mind in the following generalizations, where every statement would otherwise need to be prefaced by a proviso such as "in those species for which information is available".

All data on frogmouths show or imply that they normally live in sizeable territories, which they advertise and defend with songs and threat calls. At least in the case of *Podargus*, a single male and a single female remain on the territory throughout the year. The pair-members often roost together, sometimes in side-to-side contact, although Marbled Frogmouths are reported more often to roost solitarily. Fledged young may remain on the territory for many months, sometimes until the next breeding season, and they may occupy daytime roosts near their parents, but all of the species essentially live solitarily or in pairs. Details of post-fledging care of the young and of their dispersal are mostly unknown. Scant data on the Sri Lanka Frogmouth suggest a similar pattern of social organization.

Daytime roosts are on stumps or branches of trees or saplings, sometimes in thickets. There are reports of the Marbled and Large Frogmouths roosting in tree holes, and use of holes might possibly account for the elusiveness of some of the species during the daytime, but other species in both genera are well known to roost on open perches. When disturbed by a human observer, the roosting bird normally remains motionless with its body held at an angle above the perch, the head erect, plumage sleeked, and eyelids almost closed over the eyes to leave just narrow slits. This "broken-branch" or freezing posture, coupled with the cryptic plumage coloration and choice of roost-site, usually renders the bird very inconspicuous, so that it often relies on its camouflage and allows the observer to approach closely. Some observers have been fooled into believing that a frogmouth approached in this manner is asleep, but the bird often follows their movements by slightly twisting its head, while its eyes are not totally closed; really close approach usually results in the bird flying away quickly and silently, or with a short call that may serve to warn its mate or young. A roosting bird can occasionally be caught by hand or with a hand-held net, especially when it is

on a nest or with young, but usually it will make off at the last moment. Very close approach by intruders, however, can at times result in a prolonged gaping threat display being directed at them; this display has sometimes been interpreted as feeding behaviour, and it is possible, but unproven, that a similar posture is occasionally used for feeding (see Food and Feeding). When the

If there is a suspicion of danger during the daytime the Tawny Frogmouth will freeze, relying on this posture, together with its cryptically patterned plumage and carefully selected roost-site, to remain inconspicuous. So confident is it of this camouflage that it will allow the close approach of an observer. The bird will eventually flush when the latter gets really near, flying off silently. However, on occasion the bird still holds its ground, and the unwanted visitor is subjected to a lengthy gape display, when the bill is opened to its maximum to ensure that the threat message is sufficiently clear!

[*Podargus strigoides brachypterus*, Perth, Western Australia. Photo: Peter Steyn/Ardea]

When trying to intimidate an opponent or a potential enemy, a frogmouth will fluff out its plumage, drooping the wings and fanning the tail in an attempt to look larger than it really is. A similar posture is frequently used for quite a different purpose, namely that of drying the plumage, as is perhaps best known in the cormorants (*Phalacrocoracidae*). Note the rather long central rectrices of this Papuan Frogmouth.

Beste/Ardea]

observer retreats a fair distance, the bird eventually relaxes its freezing posture and opens its eyes more widely. Incubating birds and those accompanying nestlings also use the freezing posture when intruders approach, and it is also adopted by fledglings of the Papuan Frogmouth and probably those of some other species. On the other hand, at least in the genus *Podargus*, birds

Although by far the best documented species in the family, the Tawny Frogmouth remains shy and secretive, and detailed descriptions of its comfort behaviour are few. One interesting activity, to date only observed in captive birds, is a form of rain-bathing. During a shower, the bird will lower its wings before raising them over its head, fluffing up its feathers, and then swaying from side to side. Meanwhile it droops its head low, and sometimes calls.

approached when they are perching at night do not adopt this posture, but merely fly away if the observer comes too close. After being disturbed during the daytime, *Podargus* frogmouths are sometimes mobbed by honeyeaters (*Meliphagidae*).

All frogmouths are essentially nocturnal in their activity. *Podargus* species are commonly most active for an hour or two after dusk and again before dawn, with a lull in the middle of the night. An account of the calling behaviour of Horsfield's Frogmouth also suggests a similar pattern of activity, which is common throughout the *Caprimulgiformes*.

Very little is recorded of the displays and posturing of frogmouths, although vocalizations are evidently very important for signalling (see Voice). Tawny Frogmouths normally react to threats by flying away, but, if cornered, they are reported to fluff out their plumage, open their eyes wide and indulge in "frightening" bill-snapping that exposes the yellow gape (see Breeding). When Sri Lanka Frogmouths are disturbed at their daytime roosts, they are reported to bob the head two or three times before flying away.

Few data are available on the comfort behaviour of this family. Captive Tawny Frogmouths have been recorded sun-bathing while roosting on a branch or on the ground, prostrating themselves with outstretched wings and ruffled feathers. Allopreening has also been recorded for this species, paired birds at roosting sites preening themselves and each other about the head.

Voice

Frogmouths are often highly vocal, using "songs" to advertise and defend their territories, and uttering various other calls. For the ornithologist, the vocalizations provide the easiest means of locating and identifying most of the species, although those of the Dulit Frogmouth are still completely undescribed. The voices of several of the other *Batrachostomus* species are only partly known, while that of the Short-tailed Frogmouth has been described only very recently.

The large *Podargus* species have songs with a mellow hooting character, which may become more booming in quality at close range. Differences between their songs enable the three species to be readily identified: the ringing "coo-loo, coo-loo,

coo-loo, coo-loo, coo-loo" (4-7 phrases) of the Marbled Frogmouth is quite different from the soft "oom-oom-oom-oom..." (10-50 phrases) of the Tawny Frogmouth, or the very low-pitched, resonant "oom oom oom oom oom oom oom..." (9-13 phrases) of the Papuan Frogmouth. In all three species, both male and female sing, and in the case of both Marbled and Papuan Frogmouths the lower-pitched song is believed to be that of the female. Duetting by the two birds of a pair perhaps occurs in all three species. In any event, precisely timed antiphonal singing is reported for the Tawny Frogmouth, and songs of the Marbled Frogmouth are timed partly to overlap.

All three *Podargus* species typically sing from perches well up in trees, and Tawny Frogmouths often sing from the nest-site for long periods at the start of the breeding season. Tawny and Marbled Frogmouths may sing in many months of the year, but the song of the Papuan Frogmouth is reported to be given almost entirely in the breeding season.

These three species have several other calls that are used in territory defence, but the precise function of each of them is not well understood. As an example, studies of the Marbled Frogmouth at the Iron Range, Queensland, using playback of taped song, give some insight into the functions of song and other vocalizations. Initially, playback of such recordings is often answered from a distance by similar songs, which is in accordance with the likely role of the song in signalling the presence of territorial birds. Repeated playback of song within a territory may then lead to the pair of territory-owners approaching closely and repeatedly giving threat calls: each of them a quick series of gobbling units, becoming softer at the end and often terminating with a loud, sharp, mechanical bill-snap, "Wu-Wu-wu-w CLAK!". Prolonged taunting of the birds with further song playback may produce two other types of call: a rather soft, long, moaning hoot, "oooooooooooo...", and a quick succession of short, deep units, "to-to-to-to-to", both of uncertain significance. In addition to these calls and variants of them, the vocabulary of the Marbled Frogmouth is known to include a short trilling "brrr", a short barking "chuck" and, from the male and female feeding each other at the nest, soft squeaks, hisses and rasps. An account from New Guinea describes so-called "dual singing" lasting about 40 minutes from an adult and a fledgling, the adult giving a succession of low-pitched growls, and the young bird alternating with monotonously repeated "who" or "koooo" units. The signifi-

cance of this combined performance is uncertain but, contrary to the interpretation in the published account, it seems more likely to have involved repetition of begging and contact calls than a duetting territorial song involving a fledgling.

The vocabulary of the Tawny Frogmouth seems to be equally varied, with adults giving at least six types of call including the song, and even nestlings having numerous calls. A young bird hand-reared by Mrs F. Irby (see Relationship with Man) uttered at least seven types of call before fledging, including what was evidently the full song, "repeated sometimes an incredible number of times". In addition to those seven calls, large nestlings are reported to screech if alarmed.

Our understanding of the vocalizations of *Batrachostomus* species owes much to research by J. T. Marshall, which was carried out in parallel with his studies on the small owls of South-east Asia. He used song types in conjunction with plumage and other characters to clarify the taxonomy of several of the species. The smaller *Batrachostomus* species whose vocalizations are sufficiently well known have short, whistled or rather harsh songs, the main territorial song apparently being given by the female and a different, often less noticeable song (or call) by the male. Thus, in the Philippine Frogmouth, the female utters a single falling note like that of the Indian Scops-owl (*Otus bakkamoena*), and the male a faint trill; the female Hodgson's Frogmouth gives a single long whistle which rises and then falls in pitch, whereas the male has short calls; in Horsfield's Frogmouth, the female gives a descending "qwaa-qwaa-qwaa-qwaa" series sounding like maniacal laughter, while the male utters a plaintive single whistle. The songs of the other species are less well understood: for the Large Frogmouth, a deep, hollow-sounding tremolo and a loud wheezy call have been described; in Gould's Frogmouth, the male's song is a whistled "oooh-wheeow"; Sri Lanka Frogmouths give a soft, rapid "koooo, koooo, koooo"; and the song of a presumed female Sunda Frogmouth is a descending series of "qwaa" units, all starting on the same pitch and sounding like the "caw" of a Large-billed Crow (*Corvus macrorhynchos*). In addition to the main song or call of each sex, several other calls have been described for some of the species, but the catalogue of these is still very incomplete, and the behavioural contexts and functions of those that have been tape-recorded or described is largely unknown.

Food and Feeding

There has been no detailed study of the diet of any frogmouth, although considerable information on gut contents of adult birds

Basing themselves on the frogmouths' huge bills, early naturalists assumed that they caught their prey in mid-air like flycatchers. It now appears, however, that such behaviour is rare, and for the most part they capture insects and other food items by seizing them with the bill either on the ground or off trees. There is, in fact, a record of a Gould's Frogmouth snapping at insects in the air, and maybe this technique is more widespread than currently thought, at least in *Batrachostomus*, with their somewhat smaller bills. Note the forward facing, rather owl-like eyes of this individual.

[*Batrachostomus stellatus*, Way Kambas, southern Sumatra. Photo: Bill Simpson]

While insects form the bulk of the diet of all frogmouths, the large *Podargus* species will feed on small vertebrates as well, thanks to the huge size of their bills, as demonstrated by this Tawny Frogmouth. Such prey is often given a vigorous thrashing against the perch to ensure tenderness before it is swallowed at one gulp.

[*Podargus strigoides*, Queensland, Australia. Photo: W. K. Clifford/Nature Focus]

Tawny Frogmouths invariably build their loose, platform-like nest of small twigs and sticks some 1-7 m above the ground, in the fork of a tree. Both sexes participate in the nest building, which can take a month to complete. The material is collected from trees and shrubs, the birds breaking off twigs with their bills in flight. Material is constantly added during the few days after the eggs have been laid, and is frequently rearranged during incubation. The male is known to sit during the day, while the female roosts in a nearby tree; at night they take turns on the nest.

has accumulated for the *Podargus* species and sparser data for most, but not all, of the *Batrachostomus*. Insects, particularly large ones, are the prey items most often reported. Of these, beetles (Coleoptera) and grasshoppers and their relatives (Orthoptera) are the commonest groups, although their prominence in lists may reflect their ease of identification for ornithologists who are not expert entomologists as much as it does their frequency as prey. Other insect groups recorded include Blattodea (cockroaches), Dermaptera (earwigs), Hemiptera (bugs), Hymenoptera (wasps, bees, ants), Isoptera (termites), Lepidoptera (moths and their larvae), Mantodea (mantids), Neuroptera (lacewings), Odonata (dragonflies) and Phasmatodea (phasmids). Records of small invertebrates other than insects include spiders, myriapods (centipedes, millipedes), scorpions, crustaceans (Decapoda), earthworms and, rarely, slugs and snails.

Small vertebrates have also been recorded as prey of *Podargus*, but not of the mostly smaller *Batrachostomus* species. These vertebrate prey include frogs, taken by all three *Podargus* species, with lizards, small rodents and occasionally small birds represented in the diet of the larger Papuan and Tawny Frogmouths. Among the larger vertebrate prey taken by the Tawny Frogmouth are records of the House Mouse (*Mus musculus*), House Sparrow (*Passer domesticus*) and Brown Treecreeper (*Climacteris picumnus*). This species is reported also to exploit plagues of mice, but not to feed on carrion. Captive birds kept in England in the nineteenth century regularly ate strawberries and other soft fruits; similar foods have not been recorded in the wild, although few of them are available in this species' natural range and habitat. In northern Australia its diet is thought to include a large proportion of insects at all times of the year, but in the south a shortage of insects in winter is believed to force the birds to take more arachnids and myriapods.

Because of the difficulties of making direct observations at night, not much is known of the hunting behaviour of *Podargus* and very little information exists on that of any of the species of *Batrachostomus*. The predominant feeding technique, however, appears to consist of sallying from a prominent perch to catch

moving insects and other prey. Food is taken mainly from the ground by the Tawny Frogmouth, which usually hunts in clearings, but more often from trunks, branches or foliage by Horsfield's Frogmouth and perhaps other *Batrachostomus*. Records of flightless prey, such as caterpillars or wingless beetles, also imply that prey-capture occurs on the ground or on trunks or foliage. Indeed, despite some earlier accounts, there is little evidence of insects being captured in flight by *Podargus* species, although rare instances of such behaviour are known for the Tawny Frogmouth. M. Bartels, however, surmised that Horsfield's Frogmouth catches some prey, such as moths and alate termites, on the wing in flycatcher-like flights.

At least in the case of *Podargus* species, prey is captured in the bill, small items being swallowed immediately. Large or hard prey are carried back to the perch, where they may be shaken, mandibulated or bashed against the perch to render them easier to swallow. There are clear descriptions of a captive Tawny Frogmouth "beating mice to a pulp with its beak before swallowing them at a gulp", and of a baby mouse being "shaken to and fro with the obvious view of killing it and breaking its bones" before it was swallowed. The stronger bill of frogmouths compared with other Caprimulgiformes enables them to take tougher prey, including large, hard beetles and small vertebrates, than could be readily consumed by a *Caprimulgus* nightjar. The food-bashing behaviour of the *Podargus* frogmouths doubtless adds further to this ability, and the presence of digestive grit presumably also aids in comminuting hard food.

An intriguing record exists of apparent opportunism in foraging behaviour, also involving kleptoparasitism. This consists of a single report of a Papuan Frogmouth stealing a green tree-skink (*Dasia*) from the beak of a Helmeted Friarbird (*Philemon buceroides*), an event which occurred in the daytime.

There has been interesting speculation recently about the use of open-mouthed flycatching postures by species of both genera. Two tribesmen in Papua New Guinea reported to J. M. Diamond that the Papuan Frogmouth "sometimes sits with its mouth wide open for long periods, with a sticky substance on its palate that

Tawny Frogmouth chicks are semi-altricial and are brooded on the nest for two or three weeks. As with incubation, the daytime stint is normally taken by the male. What happens at night, however, is not well known. It is thought that both sexes take turns, but it is not clear whether there is a strict alternation of bouts, or a less rigid pattern with both sexes participating for parts of the time. Difficulties of sexing birds in the wild, especially at night, probably hinder precise conclusions being drawn from the observations.

[*Podargus strigoides*
strigoides,
Gympie,
south-east Queensland.
Photo: Cyril Webster]

might serve to attract or trap insects". Diamond later elaborated on this to suggest that the probable reason why the birds use the open-mouthed posture is that they secrete a smelly, sticky saliva inside the mouth which acts as a chemical bait and lures insect prey. R. Kannan was inclined, reasonably enough, and on the basis of his observations of gaping by Sri Lanka Frogmouths, to reinterpret these reports as being instances of gaping threat displays that had been misunderstood by the observers. Nevertheless, an early and hitherto overlooked account by Mrs Irby (see Relationship with Man) of a hand-reared fledgling Tawny Frogmouth suggests that Diamond's interpretation merits further study, especially as another overlooked old account by E. Coleman describes similar behaviour by adults of this species. Mrs Irby recorded that her fledgling "loved to sit still in the evening with his mouth wide open, shutting it with a loud snap if a mosquito or any small insect flew in".

Breeding

Unlike most caprimulgiforms, frogmouths build well-formed nests that are usually placed on branches of trees, shrubs or saplings, or sometimes on top of an epiphyte or on an old nest of some other bird species. Tawny Frogmouths may use the same nest-site repeatedly, even when nesting attempts fail, and one site was known to have been used for 21 years in succession. There is no comparable information on the re-use of nests by the other species.

The structure of the nest differs considerably between the two genera. The nest of *Podargus* species is a bulky to rather small platform of criss-crossed twigs, thin sticks, vine tendrils or plant stems, sometimes incorporating small amounts of grass culms, leaves, moss or lichen, and with a shallow cup; measuring about 10-26 cm across by 4-10 cm deep in the Tawny Frogmouth, for example, it is reminiscent of a bulky nest of a pigeon (Columbidae). The Marbled Frogmouth is reported to build smaller nests than those of its two congeners, more like the small cups of drongos (Dicuridae) than twiggy platforms; some are little more than a depression in the moss on a horizontal bough.

Although the nests of several *Batrachostomus* species are still unknown, it seems unlikely that they will be found to differ much from those of their congeners which have been described. These species build a very small, neat, firm cup that consists mainly of interwoven down plucked from the birds' own underparts, with small amounts of cobwebs, mosses, lichens or leaves; the last four materials are mainly on the outside, and serve to conceal the nest rather than contributing much to the structure. The Sri Lanka Frogmouth's nest is about 5.7-6 cm across and 3.7 cm deep at the sides, but only 1.3 cm deep in the centre. It is likely that the proportionately tiny nests of *Batrachostomus* and the small nest of the Marbled Frogmouth have been evolved to reduce predation. They are extremely well concealed, in contrast to the more substantial twiggy nests of Tawny and Papuan Frogmouths, but the latter are the two largest species of the family and therefore less likely to be at risk from predators.

Both sexes of the Tawny and Marbled Frogmouths are known to collect nest material by breaking or pulling it from trees and shrubs, and sometimes, in the case of Tawny, also from the ground. Both sexes incorporate material into the nest. For the Papuan Frogmouth, it is recorded that each member of the pair "takes turns" in breaking off twigs in flight and bringing them to the nest-site, while the other works them into the nest. Nest-building is reported to take about a month in the Papuan Frogmouth, whereas Tawny Frogmouths usually take two to four weeks, although they can apparently build a nest completely in several nights; some addition and rearrangement of material continues during incubation. Hardly anything is known of the nest-building behaviour of the *Batrachostomus* species, although nests of Hodgson's Frogmouth are reported to include down from the underparts of both male and female adults.

In the family as a whole, clutches are mainly of one or two eggs, but those of the Tawny Frogmouth sometimes consist of three and rarely of four, or perhaps even five. The commonest clutch of both Papuan and Marbled Frogmouths is one egg, with two being rare or infrequent; in the Marbled Frogmouth, normally only one nestling is reported, even from two-egg clutches.

For the most part, the *Batrachostomus* species breed in thick primary forest vegetation, and, perhaps as a consequence, the nests of some species have yet to be described.

The Sunda Frogmouth builds what is reckoned to be a typical *Batrachostomus* structure, flimsily made of soft down, lichens, pieces of bark and cobwebs, forming a shallow cup, and placed on a horizontal branch close to the trunk.

Unlike its congeners, it shows a preference for nest-sites in secondary growth on the edge of primary forest, and in Brunei nests have even been found in exotic trees in suburban gardens.

Not unexpectedly, considering the size of the nest, the clutch consists of a single egg.

The precarious nature of the nest implies that the adults must exercise great care in both incubating and brooding to avoid accidents.

[*Batrachostomus cornutus*
cornutus,
Brunei.

Heap/Planet Earth]

In the Tawny Frogmouth, the male is thought to play no part in feeding the chicks for the first two or three weeks. Very small chicks will beg for food by opening the gape wide and rocking to and fro. When older they simply reach up to take food proffered to them by the parents. When first hatched, the nestlings are covered in long white down, which is replaced after about a week by a second coat of down, this time greyer with white flecks and bars. The droppings of the young are removed for the first ten days, after which the chicks begin to defecate over the side of the nest.

[*Podargus strigoides*
strigoides,
Gympie,
south-east Queensland.
Photo: Cyril Webster]

There are apparently also interesting differences in clutch size among the species of *Batrachostomus*, so far as the limited information available allows generalizations. The two species for which nesting is best known are the Sri Lanka Frogmouth, which lays a single egg, and Hodgson's Frogmouth, which normally lays two (smaller) eggs but sometimes only one. Among the poorly known species, two-egg clutches are reported for Horsfield's, but only single eggs for Large, Philippine, Gould's, Short-tailed and Sunda Frogmouths. Laying by the Tawny Frogmouth is reported to occur at intervals varying from one to three days, but no comparable data are available for other species. The eggs are pure white and ellipsoidal, with a fine-textured surface that has only a slight gloss. They vary in size from 43-55 x 30-36 mm in the Papuan Frogmouth to 23-25 x 16-18 mm in the smallest race, *affinis*, of Horsfield's Frogmouth.

Incubation during the daytime appears to be undertaken exclusively by males. Involvement of the female in incubation at night has been established for Hodgson's Frogmouth, which sits during evening twilight and for one to two hours before dawn, and probably also for the Sri Lanka and Tawny Frogmouths, so this arrangement may apply to all species. In the Tawny Frogmouth, incubation begins when the first egg is laid, resulting in asynchronous hatching. In the genus *Podargus*, the incubating bird is fed on the nest at night by its mate, but there is no information on whether this applies also to *Batrachostomus*. The nests of *Batrachostomus* are so tiny in relation to the size of the egg that several observers have wondered how the egg remains in the nest. Since no adhesive is involved, it seems likely that arrangements are much as those adopted in roughly similar circumstances by the White Tern (*Gygis alba*); that species lays on a bare branch, with the egg never being left untended by the adult birds, and any change-overs during incubation being carried out carefully. Incubating males of species of both frogmouth genera are described as remaining motionless and always steadfastly facing in the same direction, so this behaviour may serve to reduce the chances of eggs being accidentally dislodged, as well as reducing losses to predators. Observations from hides at Tawny Frogmouth nests show that the male turns the eggs no more than once every 12 hours. This is the only species for which the incubation period has been recorded, with a duration of usually 30 days but ranging from 28 to 32 days.

In the Tawny Frogmouth, small young are brooded by both parents "alternately" for two to three weeks, and the adults are reported sometimes to help hatchlings out of the eggshell. The chicks' droppings are removed for the first 10-11 days, after which the young defecate over the side of the nest. The small chicks are reported to receive food only from the female, but this requires confirmation since it is well known that older young are fed by both parents, each of them bringing food separately to the nest. Small nestlings beg by raising the wide-open bill and making rocking movements; larger young reach up and take food held over them by a parent. Sparse information on the Papuan Frogmouth suggests that parental care in that species may be similar to that exhibited by the Tawny Frogmouth, but there is no information for most other frogmouth species.

It is clear that nestlings of all three *Podargus* species bear two successive downy plumages. In this respect they resemble the owlet-nightjars, but differ from the true caprimulgid nightjars, which have only a single down plumage. The Tawny Frogmouth nestling hatches in the first down, which is white and up to about 15 mm long; by about the seventh day this is being replaced by the second down, which is long and grey, with white flecking and barring, and paler on the underparts. Some of the second down remains on the body at fledging, being lost progressively until, by the third or fourth week, it is present only on the underparts; by the time the young are able to fly strongly, the last vestiges of down are visible about the carpal joint and the base of the underwing. The sequence is apparently similar in the Marbled and Papuan Frogmouths. Data on *Batrachostomus* nestlings are too limited for it to be said that they also have two successive down plumages, although this seems likely since the Sri Lanka Frogmouth is described as having pure white down (first down?), whereas the skin of a bird near fledging has the remaining (second?) down rufous-buff, paler beneath, with narrow darker barring. It appears reasonable to speculate that the function of the white first down of frogmouths is to make the small young conspicuous to their parents so that they are not accidentally dislodged from the nest, while the near-constant brooding of small young leaves little risk of their being seen by predators. The duller coloration of the second down presumably reduces the risk of predation, which might otherwise be high because the parents cease brooding when young are well grown.

The fledging period in the Tawny Frogmouth is 25-35 days. After leaving the nest, the young are fed by their parents for a further one or two weeks and remain with them for several months longer, sometimes until shortly before the next breeding season. The Papuan Frogmouth appears to be similar in this aspect of its biology, but there are no data for other species.

The anti-predator behaviour of incubating adult males and those tending small young appears to be designed entirely to promote concealment, with the "broken-branch" or freezing posture (see General Habits) being adopted when intruders appear. At such times the bird can often be caught by hand at the nest, and it gives no special display if approached very closely, relying on crypsis until it flees at the last possible moment. The two largest species, however, the Papuan and Tawny Frogmouths, are sometimes more aggressive in defence of their young, although such behaviour has not been reported for any of the smaller species. Papuan Frogmouths, if threatened when with young, may gape, hiss and snap the bill, or flutter at the intruder while bill-snapping. Tawny Frogmouths disturbed when brooding young may adopt a defensive-threat posture, fluffing their feathers, spreading the wings and tail, snapping the bill and clucking and hissing.

As with adults, the anti-predator behaviour of well-grown nestlings also consists mainly of promoting concealment by remaining silent and adopting the "broken-branch" posture. A large nestling Tawny Frogmouth, however, when threatened, had "the extraordinary ability to make himself uncannily grotesque", puffing itself out like a ball of fluff, giving growling and quick, repeated "too-too-too-too..." calls, drawing itself out to its full length, bending low, and swaying in a most curious manner as it called!

Movements

Although they can fly strongly, frogmouths appear to be among the most sedentary of all birds. No species is migratory; in-

deed, none is known to make even local seasonal movements. A possible sighting of the Tawny Frogmouth was reported from near Morehead in southern Papua New Guinea, but there is no confirmed record of extralimital vagrancy by any member of the family. Adults of at least the three *Podargus* species apparently remain in their territories throughout the year, although these may in extreme cases span a kilometre or two. Published statements that Tawny and Papuan Frogmouths are partial migrants appear to be erroneous. Nevertheless, some dispersal of at least young birds must surely occur, although this has not yet been documented.

While some records of frogmouths from hitherto unknown localities could be the result of short-distance movements, in many cases it seems far more likely that the birds had simply been overlooked in the area before. For example, a Horsfield's Frogmouth discovered in April 1997 in Cochinchina was apparently the first record of that species for Vietnam; the relatively widespread but fragmented distribution of Horsfield's Frogmouth, however, makes it very probable that it had always been present in that part of Vietnam but had long remained undetected.

Relationship with Man

Because most frogmouths are unobtrusive and nocturnal forest birds they are commonly overlooked, even by local people. Tribesmen in New Guinea know them and give accounts of their behaviour, although it is unclear how much in what they report is based on astute observation and how much may be surmised or possibly derived from superstitious beliefs (see Food and Feeding). European settlers in Australia became acquainted with Tawny Frogmouths, but it is quite evident from the names they used for these birds, such as "Mopoke" and "Morepork", that the species was extensively confused with the common small owl of Australia, the Southern Boobook (*Ninox boobook*).

The Tawny Frogmouth is thought to lay its eggs at intervals of 1-4 days, and asynchronous hatching may explain the marked size difference between these two chicks. Shortage of food often leads to the smaller, weaker chick being fed less regularly, so that it develops more slowly or may even finally die of starvation. After the young leave the nest, the parents continue to feed them for about two weeks, remaining to roost with them at or near the nest. Eventually, the family group will move to another roost site within the territory. Though the adults cease attending their offspring after six weeks, they will all stay together for several months until the time comes to disperse.

The true status of most frogmouth species is very difficult to gauge, given their furtive habits which mean that most are almost certainly under-recorded in surveys. Nevertheless, it is probably true to say that most species have suffered notable declines, as wholesale logging has repeatedly made inroads on their preferred habitats. The Sri Lanka Frogmouth, with its rather small range in southern India and Sri Lanka, is currently classed as Near-threatened.

Although it regularly uses second growth and bamboo thickets, habitat loss appears to be the chief threat facing it.

[*Batrachostomus moniliger*,
Sinharaja, Sri Lanka.
Photo: Bill Simpson]

Members of the genus *Podargus* are occasionally kept in captivity in zoological gardens, and the Tawny Frogmouth has bred in captivity in Australia and in Europe. The other species, however, are very rarely represented in collections of captive birds.

In the 1920's, the chance find of a Tawny Frogmouth nestling blown from its nest onto the ground by high winds and its subsequent hand-rearing by Mrs Irby led to a remarkable account of this bird's development and behaviour being published in the *Emu*, the journal of the Royal Australasian Ornithologists Union. Although written in a sentimental style that differs radically from that now used in the *Emu* and other modern ornithological publications, Mrs Irby's record of her frogmouth remains to this day unsurpassed for some details of the species' behaviour and voice.

Status and Conservation

None of the frogmouths appears in the lists of internationally threatened birds, although the Large, Dulit and Short-tailed Frogmouths are classed as Data-deficient species, the small geographical ranges of the latter two implying that they are especially vulnerable in a region where extensive forest destruction is occurring. Nevertheless, many of the species have undergone considerable reductions in range, with numerous local populations being lost or greatly threatened. The main reason for these declines is the radical degradation and fragmentation of rainforest, primarily as a consequence of logging. Since the majority of frogmouth species live in rainforest, most of them are inevitably declining as a result of this destruction of their habitats, although only for a few species have losses been well documented.

Of these, the Marbled Frogmouth in north-east Australia has given particular cause for concern, especially with regard to its southern race *plumiferus*. Recent surveys have found this form to be present at 250 sites, but within its range it is mostly restricted to tiny fragments of forest. Although not in immediate danger of extinction, it must still be regarded as one of the rarest birds in Australia, and one that will require careful monitoring if its survival is to be assured. The Sri Lanka Frogmouth of southern India and Sri Lanka has also decreased owing to forest destruction. In the Western Ghats of India, a survey in Kerala State

found 34 birds and reported that, while the species was uncommon, it did not appear to be endangered. Although the Sri Lanka Frogmouth is widespread in its namesake island, it is apparently scarce and is present only in small numbers in most regions. Nevertheless, since it occurs there in a variety of well-wooded habitats, and not just in the lowland rainforest of the south-west of the island, it is probably less immediately threatened by destruction of rainforest than are those Sri Lankan endemics which are restricted to that habitat.

The long-term survival of some of the species of rainforest-inhabiting frogmouths must depend on protection of sufficiently large areas of primary forest in which even selective logging is prevented, but a much wider importance is attached to the conservation of these habitats, of course, for their endemic biota and for other reasons. It would, however, be valuable to have much more detailed information than currently exists on the location and sizes of populations of frogmouths, especially the scarcer species such as the Dulit and the Short-tailed, as well as those which are restricted to the "best" rainforest habitats, such as the Large Frogmouth. In order for this information to be gained, it will be necessary to discover more about the vocalizations of all three of those species, and then to carry out extensive nocturnal surveys.

The only species of the Podargidae that appear to be exempt from losses brought about by destruction or degradation of forest are the three that live in other habitats, namely the Tawny and Papuan Frogmouths and, probably, the Sunda Frogmouth. The Tawny Frogmouth appears to be particularly resilient, having colonized suburban gardens and farmland with trees, and having withstood heavy mortality caused by road traffic and predation by introduced cats and foxes.

Family PODARGIDAE (FROGMOUTHS) SPECIES ACCOUNTS

PLATE 23

Subfamily PODARGINAE

Genus *PODARGUS* Vieillot, 1818

1. Marbled Frogmouth

Podargus ocellatus

French: Podarge ocellé **German:** Marmorschwalm **Spanish:** Podargo Ocelado
Other common names: Little Papuan Frogmouth; Plumed Frogmouth (*plumiferus*)

Taxonomy. *Podargus ocellatus* Quoy and Gaimard, 1830, Manokwari, New Guinea.

Plumage coloration and rainforest habitat differ from those of congeners, and may suggest some distant affinity with *Batrachostomus*; although these similarities may be at least partly due to convergent evolution; race *inexpectatus* of Solomon Is shows strong superficial resemblance to *Batrachostomus auritus*, although differs in structural details and lacks white hindneck-collar. Taxonomy of southernmost race *plumiferus* much confused in past, partly because of dearth of available specimens, leading to over-reliance on descriptions; it has been treated as a race of *P. papuensis* or of *P. strigoides*, but recent study of specimens and vocalizations leaves little doubt that it is best regarded as a race of present species. Six subspecies currently recognized.

Subspecies and Distribution.

P. o. ocellatus Quoy & Gaimard, 1830 - New Guinea, Aru Is, W Papuan Is and islands in Geelvink Bay.
P. o. intermedius Hartert, 1895 - Trobriand Is and D'Entrecasteaux Is.
P. o. meeki Hartert, 1898 - Tagula I (Louisiade Archipelago).
P. o. inexpectatus Hartert, 1901 - N Solomon Is (Bougainville, Choiseul, Santa Isabel).
P. o. marmoratus Gould, 1855 - Cape York Peninsula (N Queensland).
P. o. plumiferus Gould, 1846 - coastal E Australia from SE Queensland to NE New South Wales.

On following pages: 2. Papuan Frogmouth (*Podargus papuensis*); 3. Tawny Frogmouth (*Podargus strigoides*).

Descriptive notes. 37–48 cm; 132–180 g (*ocellatus*). Plumage coloration variable; some accounts refer to distinct colour morphs, but variation in coloration appears to be continuous between the extremes. General colour of male's upperparts ranges from dull grey-brown (often with intricate marbling and streaking) to deep rufous (often with very little marbling and few dark spots and streaks); underparts also variable, but most often with irregular whitish barring and longitudinal streaks of dark brown and blackish. Distinguished from *P. strigoides* most reliably by longer tail and different vocalizations; *P. papuensis* is much

larger, with different song. Female often darker than male, but not always separable. Juvenile not well described, but reported as rufous-brown, faintly barred white and tipped dusky on head and underparts, faintly barred dusky on back and mantle. Races differ mostly in size and details of coloration; *inexpectatus* is the most distinctive, with finer dark markings on upperparts and clear white spots on wing-coverts. **VOICE.** Highly vocal; frequently calls from perch in tree. Territorial song consists of phrase of 4–7 "coo-loo" units repeated in quick succession; threat call a quick series of gobbling units that often terminate with loud, mechanical bill-snap.

Habitat. Humid forest; in addition to rainforest, also occurs at forest edge, and in tall secondary forest and vine forest. Two unusual records of race *plumiferus* inside 20-year-old monocultures of hoop pine (*Araucaria cunninghamii*). Mainly in lowlands, but recorded up to 800 m in Australia and to 1500 m in New Guinea.

Food and Feeding. Diet consists mainly of large insects such as beetles and grasshoppers, with a single report of a frog being eaten. Hunts by hawking from prominent perch, typically within several metres of ground in forest substage, taking prey on the ground, foliage, branch or tree trunk after a shallow, diving glide; prey captured in bill. Large or hard items may be carried back to perch and battered vigorously before being eaten.

Breeding. Aug–Dec (–Feb) in Australia; few data from New Guinea suggest Mar, May, Aug–Nov; large nesting on Bougainville in Aug. Presumably single-brooded. Nest is a small, flat or shallow platform of twigs, vine tendrils, moss, etc., placed 3–15 (–25) m above ground on flat tree-fork or on crown of epiphyte. Clutch 1 egg, infrequently 2; incubation and fledging periods unknown; both sexes apparently share incubation and care of young, with confirmation from collected birds that males incubate and tend young during day; nestling has white first down. It is reported that usually only single young fledges from nests on Cape York Peninsula, even with 2-egg clutches.

Movements. Adults are apparently sedentary in territories throughout year. No information on dispersal or other movements of young birds.

Status and Conservation. Not globally threatened. Status of both subspecies in Australia gives cause for concern, since they depend on rainforest fragments. In particular, *plumiferus* has declined greatly owing to widespread destruction of its forest habitat for agriculture, grazing, and timber production, with the result that it is now a rare bird that will require careful monitoring in future; although a recent survey found it at 250 sites, many of these are in tiny fragments of forest that support very small numbers. Solomon Is race *inexpectatus* was reported to be uncommon in 1981.

Bibliography. Atherton *et al.* (1981), Barker & Vestjens (1989), Beehler (1978), Beehler & Finch (1985), Beehler *et al.* (1986), Beruldsen (1980, 1993, 1997), Bishop (1987), Blakers *et al.* (1984), Christidis & Boles (1994), Coates (1985), Condon (1975), Corben & Roberts (1993), Czechura (1979), Davis & Beehler (1993), Diamond (1972), Fleay (1979), Frith & Frith (1993), Garnett (1993), Gilliard & LeCroy (1967b), Gregory (1995a, 1995b), Hadden (1981), Harrison & Frith (1970), Hartert (1925), Higgins (1999), Hollands (1991), Holmes (1981), Lamothe (1986), Lasiewski *et al.* (1970), Lindsey (1992), Macdonald (1988), Mackay & Mackay (1974), Mathews (1927), Mayr (1945), Mayr & Rand (1937), McAllan (1995), McGill (1978), Mees (1965), Meggs (1993), Milledge (1983), Milledge & Clancy (1982), Pizzey & Doyle (1998), Rand & Gilliard (1967), Ripley (1964a), Roberts & Ingram (1978), Schodde (1977), Schodde & Mason (1981), Schodde & Tidemann (1986), Schönwetter (1964), Serventy (1936), Simpson & Day (1998), Smith, de Baar *et al.* (1994), Smith, Hamley *et al.* (1994), Strahan (1994), Tronson & Tronson (1987), Welsh (1933).

2. Papuan Frogmouth

Podargus papuensis

French: Podarge papou **German:** Papuaschwalm **Spanish:** Podargo Papú
Other common names: Giant/Great (Papuan) Frogmouth, Large Frogmouth(!)

Taxonomy. *Podargus papuensis* Quoy and Gaimard, 1830, Manokwari, New Guinea. Considerable geographical variation in size in New Guinea region, but chequerboard pattern of distribution of large and small birds makes recognition of races impractical. Although two races recognized in Australia by some recent authors, with a larger, paler form on Cape York Peninsula (*rogersi*) and a smaller, darker form in coastal NE Queensland S of Cooktown (*baileyi*), Cape York birds appear indistinguishable from those of S New Guinea and some characters of *baileyi* can be matched by certain New Guinea populations. Monotypic.

Distribution. New Guinea, W Papuan Is, islands in Geelvink Bay and Aru Is, and NE Australia in N & E Queensland (Cape York Peninsula S to R Staaten and Paluma Range).

Descriptive notes. 45–60 cm; 256–599 g. Largest of genus, with long tail; coloration rather variable, and some birds much darker than others. Male's upperparts generally appear grey-brown, but in detail have elaborate light and dark pattern; underparts generally light brown-grey, with spots and short irregular bars of white, and variable blackish streaking; irides frequently bright red, but often orange, yellow or brown. Iris colour, when red, a useful distinction from congeners. Female much like male and similarly variable, although typically with more brown or rufous tone, especially on upperparts, and less contrasting light and dark markings; rarely, female (but apparently not male) occurs as "rufous morph", almost entirely plain cinnamon. Juvenile coloration evidently very variable, from generally similar to adult to much paler, with underparts mainly white. **VOICE.** Reported to be vocal virtually only when breeding. Territorial song a low-pitched, resonant series of 9–13 units, "oom oom oom..."; several other calls are made, in addition to mechanical bill-snapping.

Habitat. In New Guinea, inhabits savanna with trees, rainforest (mainly at edge), second-growth woodland, gallery woodland, groves of trees, scrub and urban gardens; from sea-level to 1000 m, rarely to 2250 m. In Australia, occurs mainly in lowland areas, on edge of rainforest, in rainforest-scrub, vine forest, gallery and paperbark (*Melaleuca*) forest along streams, some *Eucalyptus* woodlands, swamp-woodland and mangroves.

Food and Feeding. Diet consists mostly of large beetles and grasshoppers, but also includes other insects, spiders, myriapods, snails, lizards, rodents and even small birds. Hunts by sallying from a prominent perch, such as a low bare branch, stump or fence, planing down in a shallow, noiseless glide to catch prey in the bill; a single report of a green tree skink (*Dasia*) snatched from the beak of a Helmeted Friarbird (*Philemon buceroides*) in daylight. Large and hard prey items are carried back to the perch and bashed and crushed before being swallowed.

Breeding. Season in Australia Jul–Feb, mostly Aug–Dec, with peak Oct–Nov; incomplete information from New Guinea suggests laying mainly in dry season, e.g. at least Jul–Nov in Port Moresby region, with adults on nests in Oct and Nov on N coast, and fledgling on Misool in Jan. Single-brooded (Australia). Nest is a rough platform, rather scanty or substantial, of criss-crossed twigs, placed on horizontal fork of tree mostly 6–20 m (2.4–36 m) above ground. Clutch 1 egg, rarely 2; probably both sexes incubate, although only males have been collected from nests during the day; incubating bird always faces in same direction on nest, and at night one of pair constantly feeds and attends the other; incubation period not reported; nestling has white first down, whitish-fawn to fawn second down; young fed by both adults alternately, at least when small; fledging period unknown; fledged young begin to fend for themselves about 1 month after leaving nest, but may remain with parents almost until beginning of next breeding season.

Movements. Although some Australian literature suggests that species is migratory, this is based on old anecdotal accounts that were probably mistaken. Adults occupy the same territory throughout year. No information on dispersal of young birds.

Status and Conservation. Not globally threatened. Apparently remains common in parts of its limited Australian range; in New Guinea generally not uncommon, and locally fairly common (e.g. in Varirata National Park). Unlike many Australian rainforest birds that have declined as a result of habitat loss, it can tolerate some clearing and agricultural development, and is therefore still present over much of its historical range.

Bibliography. Angus (1994), Atherton *et al.* (1981), Barker & Vestjens (1989), Beehler (1978), Beehler & Finch (1985), Beehler *et al.* (1986), Bell (1986), Beruldsen (1980), Blakers *et al.* (1984), Clapp (1982), Clapp & Haera (1982), Coates (1985), Condon (1975), Diamond (1972, 1994), Draffan *et al.* (1983), Fleay (1979), Frith & Frith (1986, 1993), Gill (1970), Gilliard (1950b), Gilliard & LeCroy (1966), Gregory (1995a, 1995b), Hall (1974), Hicks (1989, 1992b, 1992c), Higgins (1999), Hollands (1991), Kannan (1994a), Lindsey (1992), Macdonald (1988), Mackay (1975), Madsen & Larsson (1953), Mathews (1927), Mayr (1937b, 1941a), Mayr & Gilliard (1954), Mayr & Rand (1937), McNab & Bonaccorso (1995), Mees (1965, 1982b), Pizzey & Doyle (1998), Rand (1942b), Rand & Gilliard (1967), Ripley (1964a), Rowland (1995b), Schodde & Mason (1981), Schodde & Tidemann (1986), Schönwetter (1964), Simpson & Day (1998), Strahan (1994), Tolhurst (1993), Tronson & Tronson (1987).

3. Tawny Frogmouth

Podargus strigoides

French: Podarge gris **German:** Eulenschwalm **Spanish:** Podargo Australiano
Other common names: Freckled/Tawny-shouldered Frogmouth, Mopoke, Morepork(!), Night Hawk, Podargus

Taxonomy. *Caprimulgus strigoides* Latham, 1801, New Holland = Sydney, New South Wales. Possibly the most divergent member of the genus; coloration, proportionately long and pointed wings, short tail and strong feet are all adaptations to its relatively dry woodland habitat. Wide individual and sexual, as well as geographical, variation in coloration and size led to naming of numerous races in past; proposed races *lilae* (Groote Eylandt) and *gouldi* (NE Australia) included in *phalaenoides*, while *cornwalli* (E Queensland), *victoriae* (SC Australia) and *cuvieri* (Tasmania) all now lumped into nominate; much of the variation now known to be clinal, resulting in various recent treatments reducing number of valid races to five, three, two or none, but detailed studies now indicate three should be accepted. Three subspecies currently recognized.

Subspecies and Distribution.

P. s. phalaenoides Gould, 1840 – throughout N Australia, S to Great Sandy Desert, Barkly Tableland and S plains of Gulf of Carpentaria in Queensland.

P. s. brachypterus Gould, 1841 – Western Australia (N to Great Sandy Desert) NE to Channel Country of Queensland and SE to Murray mallee in Victoria.

P. s. strigoides (Latham, 1801) – E & SE Australia (S from N of Cooktown, W to inland fringes of Great Dividing Range and SE South Australia) and Tasmania.

A single unconfirmed sight record (subspecies uncertain) from near Morehead in S Papua New Guinea.

Descriptive notes. 34–53 cm; 205–364 g (*phalaenoides*), 180–680 g (*strigoides*). Coloration very variable, but upperparts normally greyish, boldly streaked black, with intricate finer barring and vermiculation; underparts pale greyish, with thin to strong blackish streaks, variable brown to rufous suffusion and variable amounts of irregular white barring. Female often darker than male, with much more rufous suffusion, but true rufous or chestnut morph uncommon. Juvenile apparently much like adult in coloration, although often with less contrasting dark markings and with softer-textured plumage. Race *phalaenoides*

smaller, pale and delicately marked, with rufous-morph female commoner than in other races but connected to greyer birds by intermediates; *brachypterus* medium-sized, tends to look rather plainer and perhaps greyer, with no rufous-morph female known. **VOICE.** Calls frequently, especially in breeding season. Song is soft, rather unobtrusive, low-pitched "oom-oom-oom...", typically repeated 10–50 times in successive bursts. Has numerous other calls, and sometimes gives mechanical bill-snaps when threatened.

Habitat. Requires trees or shrubs in which to roost and nest, and perches from which it can hunt in open places, so occurs in most types of country with trees or scrub, including *Eucalyptus* forest and woodland, mulga, trees along watercourses, mallee, coastal scrub, tree-lined roadsides in farmland, city parks and large gardens with trees. Avoids treeless semi-desert and usually the interior of rainforest, although it readily colonizes edges of roadways in rainforest areas.

Food and Feeding. Diet consists mainly of large insects and other terrestrial invertebrates (scorpions, spiders, centipedes); also takes frogs, and occasionally earthworms, snails, slugs, crustaceans

(Decapoda), millipedes, lizards, small birds and small mammals. Typically hunts by sallying from exposed perch, such as an open branch or fence post adjacent to open ground, from which it glides to capture moving prey from the ground or, less often, from branches; often feeds from roadsides, resulting in many birds being killed by traffic. Large or tough prey items are beaten against the perch before being swallowed.

Breeding. Season apparently similar throughout range, mostly Aug-Dec, with peak of laying Sept-Oct. Normally single-brooded; reports of second brood unconfirmed. Nest a coarse, loose and often flimsy, shallow, almost flat platform of criss-crossed thin sticks and twigs, placed on fork of tree, less often on old nest of another bird or on epiphyte, generally 3-10 m (2-20) above ground. Clutch 1-3 eggs, usually 2, rarely up to 5; incubation 28-32 days, by male during day, but female thought to incubate at night; parents feed each other at nest at night; nestling has first down white, second down grey with white flecking and barring and paler underparts; young brooded and fed by both parents; fledging 25-35 days; fledged young fed by parents for 1-2 weeks after leaving nest, and may remain with them for several months longer.

Movements. Adults appear to be sedentary throughout year on their territories; seasonal movements suggested by some authors, but these are unconfirmed and seem unlikely. Extent of dispersal of young birds unknown.

Status and Conservation. Not globally threatened. Remains common over much of Australia, though has declined in some areas, e.g. S Mt Lofty Ras, SE South Australia and Wheatbelt of Western

Australia. A successful colonist of farmland and many built-up areas; often sighted in urban parks and gardens, and in trees lining streets; adversely affected by wholesale extraction of trees to make way for agriculture, but may benefit from partial clearance of dense forest. Evidently capable of withstanding considerable mortality from road traffic, as well as losses due to predation from introduced cats and foxes; however, numbers killed by traffic in N Sydney have dropped notably since early 1970's, possibly reflecting population decline; other man-related negative factors on record include pesticide poisoning, nest disturbance, shooting of birds by vandals, and death caused by birds flying into wire fences. Frequently kept in zoos and bird parks.

Bibliography. Anon. (1995b), Barker & Vestjens (1989), Beruldsen (1980), Blakers *et al.* (1984), Carter *et al.* (1985), Coleman (1946a, 1946b), Condon (1975), Corben & Roberts (1993), Davis & Beehler (1993), Deignan (1951), Disher *et al.* (1995), Dove (1928), Fish (1996), Fleay (1925, 1936, 1979), Ford (1986), Gerrits (1956), Goudswaard (1983), Higgins (1999), Hollands (1991), Holmes (1981), Irby (1927), Kingston (1980), Kutt (1994), Lasiewski & Bartholomew (1966), Lindholm (1988), Lindsey (1992), Lord (1956), Macdonald (1988), Mackay (1976), Mathews (1927), McAllan & Bruce (1989), McCulloch (1975), McNab & Bonaccorso (1995), Mees (1961), Milledge & Clancy (1982), O'Brien (1990), Pizzey & Doyle (1998), Ragless (1955, 1957), Rason (1986), Roberts & Ingram (1978), Rose (1973a, 1976), Rose & Eldridge (1997), Rutgers & Norris (1972), Schodde & Mason (1981), Schodde & Tidemann (1986), Schönwetter (1964), Serventy (1936), Serventy & Whittell (1962), Simpson & Day (1998), Storr (1984), Strahan (1994), Stresemann & Stresemann (1966), Tarr (1985), Thomas (1957), Trounson & Trounson (1987), Vestjens (1973).

4. Large Frogmouth

Batrachostomus auritus

French: Podarge oreillard **German:** Riesenfroschmaul **Spanish:** Podargo Orejudo

Taxonomy. *Podargus Auritus* J. E. Gray, 1829, no locality = Sumatra.

Forms a superspecies with the Bornean montane endemic *B. harterti*. Monotypic.

Distribution. Scattered localities in Peninsular Thailand (Nakhon Si Thammarat), Malaysia and Sumatra to Borneo and nearby N Natuna Is and Labuan I.

Descriptive notes. 40-43 cm; c. 206 g. Largest of the Asian frogmouths, although *B. harterti* not much smaller. Adult chestnut to light brown above, with pale bars on scapulars and blackish-edged white or buffy-white spots on wing-coverts; underparts rufous-brown, often with some buff to white spots. No obvious sexual dichromatism. Juvenile apparently differs from adult in having upperparts mainly grey-brown with fine vermiculation of pale buff, and underparts light grey-brown with rufous tinge, paler on belly. Voice. Poorly known; variously described as a loud wheezy call, and as a deep, hollow-sounding tremolo which may

be repeated up to 8 times; also, a repeated rippling "coerr".

Habitat. Lowland rainforest, but recorded from secondary forest as well as undisturbed primary forest; also forest in swamps and on alluvial soils.

Food and Feeding. Diet includes cicadas and grasshoppers. Apparently feeds by sallying to catch insects on the ground or from branches.

Breeding. Season unrecorded. Nest a rather small but thick, circular pad of fine down firmly attached to a slender branch of a shrub or sapling; one was 1-3 m above the ground. Clutch apparently 1 egg; incubation and fledging periods, and roles of sexes in each, unknown; nestling apparently has white down.

Movements. Appears to be sedentary.

Status and Conservation. Not globally threatened. Data-deficient. Extremely rare in Thailand, where possibly only one definite record exists. Rare in Malaysia, but still recorded in areas of fragmented forest around Kuala Lumpur and nearby parts; recent records in three different parts of Taman Negara National Park. Rather few records from Sumatra, where species might be threatened; however, report from Gunung Leuser National Park in 1988, and new provincial records from Riau (a bird mist-netted in 1991) and Lampung (several records from Way Kambas National Park in 1994 and 1995), suggest that it may be more widespread than previously suspected. Seems to be very uncommon in Borneo, where only local in occurrence; recorded in Gunung Mulu National Park, Sarawak, and in Danum Valley Conservation Area, Sabah. In general, apparently an uncommon or rare bird that is almost certainly declining owing to destruction of its lowland-forest habitat, but it is an elusive and little-known species.

Bibliography. Andrew (1992), van Balen (1968), Chasen (1939), Collar *et al.* (1994), Danielsen & Heegaard (1995), Holmes (1996, 1997), Lekagul & Round (1991), MacKinnon & Philipps (1993), Mann (1987), van Marle & Voous (1988), Marshall (1978), Medway & Wells (1976), Nash, A.D. & Nash (1985), Nash, S.V. & Nash (1985, 1988), Parrott & Andrew (1996), Round (1988), Sheldrake (1916), Smythies (1957, 1981), Steinbacher (1950), Stresemann (1937), Stresemann & Stresemann (1966), Wells, D.R. (1985, 1990, 1999).

5. Dulit Frogmouth

Batrachostomus harterti

French: Podarge de Hartert **German:** Hartertfroschmaul **Spanish:** Podargo del Dulit

Taxonomy. *Batrachostomus harterti* Sharpe, 1892, Mount Dulit, c. 700 m [2000 feet], north Borneo. Forms a superspecies with the more widespread, lowland *B. auritus*; both occur at Mt Dulit, with *B. auritus* recorded only at lower elevations; reports of specimens intermediate between the two are apparently erroneous. Monotypic.

Distribution. Mountains of N & C Borneo: known from Mt Dulit, Usun Apau Plateau, Kelabit Uplands (all Sarawak) and Mt Liang Kubung (Kalimantan).

Descriptive notes. 34-37 cm. Coloration very similar to that of the darkest individuals of *B. auritus*, from which it is reliably distinguished only by slightly smaller size (wing 220-229 mm, against 248-278 mm in *B. auritus*). Sexes much alike. Juvenile plumage unknown. Voice. Not described.

Habitat. Apparently lives in forest at sub-montane levels; reliable records at 600-1230 m, reports from lower elevations presumed to be errors.

Food and Feeding. No information.

Breeding. No information.

Movements. No information; presumably sedentary, like congeners.

Status and Conservation. Not globally threatened. Data-deficient. Restricted-range species; present in Bornean Mountains EBA. Apparently known only from seven skins (six from Sarawak and one

from Kalimantan), with no information on its status, past or present. Potentially at risk from deforestation or from collection of specimens. Species clearly in urgent need of intensive study to determine, among other things, its ecology, biology and population levels.

Bibliography. Andrew (1992), Collar & Andrew (1988), Collar *et al.* (1994), MacKinnon & Philipps (1993), Marshall (1978), Sharpe (1892a, 1892b), Smythies (1957, 1981), Stattersfield *et al.* (1998), Stresemann (1937), Stresemann & Stresemann (1966), Sujatnika *et al.* (1995), Warren (1966), Wells (1985).

6. Philippine Frogmouth

Batrachostomus septimus

French: Podarge des Philippines **German:** Philippinenfroschmaul **Spanish:** Podargo Filipino
Other common names: Menage's/Small-billed/Tweeddale's Frogmouth

Taxonomy. *Batrachostomus septimus* Tweeddale, 1877, Pasananca, near Zamboanga, Mindanao, Philippines.

Three subspecies recognized.

Subspecies and Distribution.

B. s. microrhynchus Ogilvie-Grant, 1895 - Luzon and Catanduanes.

B. s. menagei Bourns & Worcester, 1894 - Panay and Negros.

B. s. septimus Tweeddale, 1877 - Bohol, Leyte, Samar, Mindanao and Basilan.

Descriptive notes. c. 25 cm; 75-96.5 g (*septimus*). Nominative form occurs in two colour morphs, connected by intermediates. Adult male has whitish collar across mantle, bold white spots on wing-coverts and much white or pale buff on scapulars; chestnut morph has upperparts mainly rufous-chestnut and ground colour of most of underparts deep rufous; mottled morph has upperparts and underparts mainly light brown with intricate barring of buff and blackish. Distinct from all other *Batrachostomus* in being medium-sized, with relatively short tail. Polymorphic variation formerly misinterpreted as sexual dichromatism; in fact,

female of both morphs differs from male in having narrower white collar across mantle, less white on wing-coverts and no white or pale buff on scapulars. Juvenile undescribed. Races differ mainly in size, with northernmost populations (*microrhynchus*) markedly smaller than nominate, but the two known skins of *menagei* are intermediate in size and come from geographically intervening islands; too few specimens to be sure of occurrence of morphs in both sexes of *menagei* and *microrhynchus*, although both morphs do at least occur in latter race. Voice. Territorial song of female is a single falling note; call of male a faint trill.

Habitat. Forest and near forest edge, from the lowlands to c. 2500 m.

Food and Feeding. No information available.

Breeding. Season Apr-Jun/Jul. Nest described as a small cup of vegetation, placed on tree branch; three reports all refer to nests with single egg; no further information available.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. Described as an uncommon species, so some populations are likely to be at risk in view of the extensive deforestation taking place throughout most of the Philippines. Research and survey work required.

Bibliography. Brooks *et al.* (1996), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), Evans, Dutton & Brooks (1993), Gonzales (1983), Goodman & Gonzales (1990), Hachisuka (1930, 1934), Heaney & Regalado (1998), Marshall (1978), McGregor (1904), duPont (1971), Rabor (1938a), Rand & Rabor (1960), Schönwetter (1964), Steinbacher (1949), Stresemann (1937), Whitehead (1899).

7. Gould's Frogmouth

Batrachostomus stellatus

French: Podarge étoilé **German:** Schuppenfroschmaul **Spanish:** Podargo Estrellado

Taxonomy. *Podargus Stellatus* Gould, 1837, Java; error = Malacca.

Apparently a rather isolated species in the genus, differing from other small *Batrachostomus* in lacking sexual dichromatism and in pattern of underpart feathers. Although recognition of Bornean population as a separate race (*parvulus*) is sometimes suggested, geographical variation of species is slight at most. Monotypic.

Distribution. C peninsular Thailand (S from Surat Thani) through peninsular Malaysia (S to Negeri Sembilan) to Sumatra, then E through Riau (Bintan) and Lingga (Lingga) Archipelagos and Bangka to Borneo and Natuna Besar I.

Descriptive notes. 21-25 cm; 47-48.5 g. Occurs in two colour morphs. Adult has narrow whitish collar across mantle, bold whitish spots on wing-coverts and white or greyish-white spots on scapulars, the underparts with oval-shaped buffish spots; chestnut morph has ground colour of upperparts mainly chestnut, that of scarcer dark morph darker, almost blackish-chestnut. Sexes similar (in most but not all of the literature, polymorphic variation in this species misinterpreted as sexual dichromatism). Juvenile also dimorphic, chestnut morph having dull rufous-chestnut upperparts with narrow, ill-defined darker barring, dark morph similar but darker overall, and both plainer and less spotted. Voice. Male's song is a phrase of 2 units, the second higher than the first and connected to it by a brief tremolo. Territorial song of female apparently not described.

Habitat. Rainforest; reported to live in the lower storey and to prefer dense forest; one nest was found in secondary forest. Occurs mainly in the lowlands, up to 500 m; one record at c. 920 m in Borneo.

Food and Feeding. Diet known to include Orthoptera, and also moths and beetles. No further information available.

Breeding. Season poorly known; young in peninsular Malaysia in Jun and Aug; an oviduct egg in Borneo at end of Apr. Few nests described, in all cases a small, neat pad with shallow cup placed on top of thin horizontal branches; one was c. 1.3 m above ground. One clutch contained 1 egg; nestling apparently has white down; incubation and fledging periods, and roles of each sex in caring for eggs and young, unknown.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Although a relatively wide-ranging species, it is doubtless at risk in some areas owing to destruction of lowland rainforest; in Thailand, such loss of habitat has led to its now being regarded as a nationally threatened species. In Sumatra, the only recent reports are from Way Kambas National Park, where species recorded in 1984, 1985 and 1991.

Bibliography. Andrew (1992), Chasen (1931, 1939), Holmes (1996), Lekagul & Round (1991), MacKinnon & Philipps (1993), van Marle & Voous (1988), Marshall (1978), Mayr (1938), Medway & Wells (1963, 1976), Mees (1986), Parrott & Andrew (1996), Riley (1938), Round (1988), Schönwetter (1964), Smythies (1957, 1981), Steinbacher (1949), Stresemann (1937), Stresemann & Stresemann (1966), Voous (1961), Wells, D.R. (1985, 1990, 1999).

8. Sri Lanka Frogmouth

Batrachostomus moniliger

French: Podarge de Ceylan **German:** Ceylonfroschmaul **Spanish:** Podargo de Ceilán
Other common names: Ceylon/Ceylonese/Sinhalese Frogmouth

Taxonomy. *Batrachostomus moniliger* Blyth, 1849, Sri Lanka.

Resembles *B. hodgsoni* in coloration and pattern, and the two species replace each other geographically, but differences in the facial bristles, clutch size, egg size and adult plumage markings imply that they are probably too dissimilar to be regarded as forming a superspecies. Species name sometimes misspelt *monileger*. Monotypic.

Distribution. S India, in high-rainfall areas of Western Ghats from N Kanara district (Karnataka) S to Trivandrum district (Kerala); and Sri Lanka, except in dry N & SE regions.

Descriptive notes. 22–23 cm. A small, sexually dichromatic species, with adult coloration and pattern almost constant for each sex. Male brownish-grey with black and white vermiculations, narrow whitish collar across upper mantle, and white spots on scapulars, wing-coverts, belly and irregularly across breast. Differs from *B. hodgsoni* in greyer coloration and less heavily marked underparts. Female rufous or rufous-brown and more uniform, with less distinct collar and fewer spots. Juvenile female apparently has coloration much as adult female, but with softer-textured plumage; juvenile male also appears to be similar.

but few immature specimens available. Voice. Mainly a soft, rapid series of "koo-roo, koo-roo, koo-roo" units, though various other vocalizations also reported.

Habitat. Woodland and forest; often found in dense vegetation such as bamboo thickets or in second growth, remaining mainly in the understorey. Occurs from sea-level up to 1200 m, possibly to 1800 m.

Food and Feeding. Little known. Recorded prey includes grasshoppers and a beetle. Catches insect prey on the ground or on branches.

Breeding. Season apparently long, in S India chiefly Jan–Apr, occasionally Jun–Sept; in Sri Lanka mainly Feb–Mar, occasionally Sept. Nest is a small circular pad composed mainly of the birds' own down, placed on horizontal branch or in fork of small tree 2–6 m above ground. Clutch 1 egg; incubation by both sexes, by male during the day; nestling has first down white, second down rufous-buff, paler beneath, with narrow dark barring; incubation and fledging periods and care of young undescribed.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Recent surveys suggest that it is local and uncommon in S India, but not endangered, although destruction of wet forest in Western Ghats continues. Widespread in Sri Lanka, but apparently scarce or rare; frequently recorded in Sinharaja Forest Reserve. Possibly under-recorded throughout range.

Bibliography. Ali & Ripley (1983), Baker (1934a, 1934b), Borges (1986), Daniels (1997), Gaston & Zacharias (1996), Grimmer et al. (1998), Henry (1998), Hoffmann (1998), Kannan (1993a, 1994b, 1998), Lamsfuss (1998), Legge (1983), Marshall (1978), Phillips, W.W.A. (1947, 1978, 1979), Ripley (1982), Schönwetter (1964), Serventy (1936), Steinbacher (1949), Stresemann (1937), Stresemann & Stresemann (1966), Sugathan (1981), Sugathan & Varghese (1996), Vijayan (1978).

9. Hodgson's Frogmouth

Batrachostomus hodgsoni

French: Podarge de Hodgson **German:** Langschwanz-Froschmaul **Spanish:** Podargo Colilargo

Taxonomy. *Otothrix hodgsoni* G. R. Gray, 1859, northern India = Darjeeling, Sikkim.

Resembles *B. moniliger* in coloration and pattern, and the two species replace each other geographically, but differences in the facial bristles, clutch size, egg size and adult plumage markings suggest that they are probably too dissimilar to be regarded as forming a superspecies. Sometimes treated as a race of *B. javensis*, but differences in bill size and structure, development of facial bristles, relative tail length and vocalizations, and also perhaps in bare-part colours (bill said to be darker), too great for them to be considered even as forming a superspecies. Populations from S parts of Myanmar to Indochina often separated racially as *indochinae*; they average smaller and shorter-tailed, but measurements overlap with those from India. Manipur birds ("*ruphandi*") are apparently inseparable from other Indian populations. Monotypic.

Distribution. Hills and lower mountains of NE India (Sikkim, Assam and Arunachal Pradesh S to Manipur and Tripura) and SE Bangladesh through N, W & E Myanmar to SW China (SW Yunnan), NW Thailand, NW & S Laos and C Vietnam (Annam).

Descriptive notes. 22–27 cm; 51 g. A small *Batrachostomus* with well-marked sexual dichromatism, but little variation in coloration of adult of either sex. Male rufous-brown above, heavily marked with black, with white spots on scapulars and upper mantle, where may form collar; black, white

and lower montane slopes, at 300–1900 m elevation.

Food and Feeding. Diet consists of moths, beetles and other large insects. Recent accounts suggest that food is hawked in air or taken on ground or from branches; older accounts of feeding behaviour probably unreliable.

Breeding. Season Apr–Jul in NE Indian region; laying in Annam in late Feb or early Mar. Nest is a small, neat pad composed mainly of the birds' down, placed on bare or nearly bare horizontal branch c. 1.5–5 m above ground. Clutch usually 2 eggs, sometimes 1; male incubates during daytime, female in evening twilight and for 1–2 hours before dawn; incubation and fledging periods and care of young undescribed; nestling has (second?) down bright rufous or dull buff with darker barring.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Apparently rare in many parts of E Himalayas and foothills, and certainly rare in Bangladesh; formerly rare in much of Myanmar, except in Chin Hills; uncommon in Thailand, but not regarded as a threatened species there. Current status poorly known throughout range.

Bibliography. Ali & Ripley (1983), Ali et al. (1996), Baker (1934b), Delacour & Greenway (1940), Dickinson (1970), Evans & Timmins (1998), Grimmer et al. (1998), Harvey (1990), Lekagul & Round (1991), Marshall (1978), Pilo et al. (1996), Ripley (1982), Round (1988), Schönwetter (1964), Serventy (1936), Smythies (1944, 1986), Stresemann (1937), Thewlis et al. (1996), Wang Sung (1998), Zhao Zhengjie (1995).

10. Short-tailed Frogmouth

Batrachostomus poliophus

French: Podarge à tête grise **German:** Graukopf-Froschmaul **Spanish:** Podargo Colicorto
Other common names: Pale-headed Frogmouth; Bornean/Sharpe's Frogmouth (*mixtus*)

Taxonomy. *Batrachostomus poliophus* Hartert, 1892, Padang, West Sumatra.

Race *mixtus* has often been regarded as a separate species, an arrangement apparently initiated in 1937 by cautious uncertainty expressed regarding the characters of the then unknown male of the nominate form. Subsequent to the latter being described in 1938, the two forms seem not to differ greatly in coloration of either sex, and the extreme measurements of each closely approach those of the other, so that their treatment as races of the same species would seem more appropriate; possible differences in vocalizations, however, require investigation. Two subspecies recognized.

Subspecies and Distribution.

B. p. poliophus Hartert, 1892 – Sumatra.

B. p. mixtus Sharpe, 1892 – Borneo.

Descriptive notes. 20–22 cm. A sexually dichromatic species, with no apparent polymorphic variation in coloration; sexes confused in early accounts. Male dull dark rufescent-brown with buffish-white collar across upper mantle, and bold white spots on scapulars and wing-coverts; breast with white scallop-shaped markings, flanks and belly whitish with brownish edges to feathers. Differs from other small, sexually dichromatic *Batrachostomus* in combination of relatively short tail and details of coloration (as well as sub-montane distribution). Female brighter, deep rufous to chestnut, with reduced white

spotting, and often narrower collar. Juvenile plumage unknown. Voice. Only very recently described, for both races. Song (perhaps call) said to be a fairly loud undulating whistle, rising in pitch, followed by 5–7 descending liquid notes. Song (or call) of *mixtus* described as a whistled "weeow" repeated at c. 3-second intervals, each note sometimes wavering towards end; also high-pitched "chiok, chiok, chiok" series, perched or in flight, possibly as alarm.

Habitat. Sub-montane primary forest and mixed pine forest. Generally tends to occur at somewhat higher altitudes than other *Batrachostomus*: recorded at 600–1400 m in Sumatra; in Borneo mostly 610–1700 m, occasionally to 2540 m.

Food and Feeding. Gut contents of specimens examined included remains of small beetles and small Orthoptera.

Breeding. Few data. Known mainly from a single nest found in Sumatra in Jun 1933: a small pad with shallow cup, built mainly of down from birds' underparts, placed c. 5 m above ground at fork of inclined branch of a sapling; it held 1 partly incubated egg, and the male incubated during the daytime.

Movements. No information, but presumably sedentary like its congeners.

Status and Conservation. Not globally threatened. Both races listed as Data-deficient. Restricted-range species: present in Sumatra and Peninsular Malaysia EBA and Bornean Mountains EBA. Reported as uncommon in Sumatra, though several records in 1990's from N and W. Probably not common in Borneo, but occurs in Mt Kinabalu and (almost certainly) Gunung Mulu National Parks; recent record from S Kalimantan probably refers to present species. In both Sumatra and Borneo, species appears to have a relatively small range, in parts of which the forest is being destroyed; specimens are few in collections. The species' voice, however, is still poorly known, having only recently been described, so that its true status is difficult to judge.

Bibliography. Andrew (1992), Bartels (1938), Collar et al. (1994), Davison (1997a), Holmes (1996, 1997), Hoogerwerf (1962), Inskipp et al. (1996), MacKinnon & Philipps (1993), van Marle & Voous (1988), Marshall (1978), Philipps (1981/82), Schönwetter (1964), Sharpe (1892c), Smythies (1957, 1981), Stattersfield et al. (1998), Steinbacher (1949, 1950), Stresemann (1937, 1938b), Sujatnika et al. (1995), Vowles & Vowles (1984), Wells (1985).

11. Horsfield's Frogmouth

Batrachostomus javensis

French: Podarge de Java **German:** Javafroschmaul **Spanish:** Podargo de Java
Other common names: Javan Frogmouth; Blyth's Frogmouth (*affinis*); Indochinese Frogmouth (*continentalis*); Palawan Frogmouth ("chasei")

Taxonomy. *Podargus Javensis* Horsfield, 1821, Java.

Much confusion over species-limits with regard to this and its close allies. Formerly considered conspecific with *B. cornutus* by some, but a combined study of vocalizations and museum specimens in 1978 confirmed earlier suggestions that it should be regarded as a distinct species. Race *affinis* sometimes considered a distinct species. Sometimes treated as conspecific with *B. hodgsoni*, but differences in bill size and structure, development of facial bristles, relative tail length and vocalizations, and also perhaps in bare-part colours (bill said to be often more straw-coloured), too great for them to be considered even as forming a superspecies. Race *continentalis* is apparently connected to *affinis* by an intermediate population around Khao I Phrom in C peninsular Thailand. Birds from Palawan, Culion I and Banggi I often separated as race *chasei*, but appear inseparable from *affinis*; recent claim of a new species (*B. pygmaeus*) from Palawan (Basuanga I) seems unconvincing, the single specimen on which description is based being little different from local "chasei" (= *affinis*). Three subspecies recognized.

Subspecies and Distribution.

B. j. continentalis Stresemann, 1937 - SE Myanmar (S Tenasserim) and N, W & S Thailand (S to Nakhon Si Thammarat); also S Laos and C Vietnam (Annam).

B. j. affinis Blyth, 1847 - SE peninsular Thailand S to Sumatra and Riau Archipelago, then E through Borneo and Banggi I (off N Borneo) to W Philippines (Palawan, Culion I).

B. j. javensis (Horsfield, 1821) - Java.

Descriptive notes. 19-25 cm; mean 46-47 g. A small, sexually dichromatic *Batrachostomus* with no polymorphism in plumage coloration. Male brown above, speckled white and with distinct black spots; whitish supercilium, whitish collar across upper mantle, and much white on scapulars; spotted cinnamon, buff and white below, belly and flanks brown-barred whitish. Female notably brighter and plainer, with less white. Juvenile little known, but said to be pale rufous with faint barring and speckling above; a juvenile male of race *affinis* had plumage softer-textured than adult, coloration much more rufous in tone than adult male, with

more prominent dark barring, and underparts more like adult female. Races differ mainly in tone of coloration, or details of colour pattern, or both. Voice. Territorial song of female a frenzied, descending series of 3-5 units, sounding like maniacal laughter; male gives a plaintive whistle.

Habitat. Mainly lowland evergreen forest, preferring dense rainforest, in which it lives mostly in the understorey. Also reported from tree-rich scrub in Java, and occurs locally in mixed deciduous forest in Thailand, including that on limestone crags; recorded in mangroves in S Sumatra; some accounts list second growth among its habitats. Occurs from sea-level up to 1600 m, but to 1700 m in W & C Java and to 2150 m in E Java.

Food and Feeding. Diet consists mainly of insects, particularly beetles and grasshoppers; other records from gut contents include moths, caterpillars, earwigs, cockroaches, termites and a snail. Scant information implies that prey is captured mainly by fluttering at leaves and trunks, with some perhaps taken from ground or in flight.

Breeding. Few data on season: 2 nests with eggs in Malaysia in Feb and Mar, and 1 with nestlings in Palawan in Jul; possibly Jan-Apr in Borneo, and Feb to mid-Jun in Java. Nest is a small rounded pad with shallow cup, built mainly from the birds' own down, placed on branch of small sapling or a *Saccharum* cane. Clutch 1-2 eggs; a male has been recorded incubating during the daytime; incubation and fledging periods and care of young undescribed.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Currently considered Near-threatened; this assessment probably results from taxonomic confusion, since only the Javan nominate subspecies is scarce, although local populations in many other regions are at risk from deforestation. Status uncertain in Sumatra, but several recent records from Way Kambas National Park. On Palawan, regularly recorded in St Pauls National Park. Calls thought to refer to present species heard relatively commonly in Laos during fieldwork in mid-1990's. Despite its relatively wide distribution, species remains poorly known, and may well be under-recorded throughout much of range.

Bibliography. Andrew (1992), Bartels (1938), Bernstein (1860), Chasen (1931, 1939), Delacour & Mayr (1946), Dickinson *et al.* (1991), Duckworth (1996), Evans & Timmins (1998), Hachisuka (1934), Holmes (1996, 1997), Holmes & Burton (1987), Hoogerwerf (1962), Hoogstraal (1951), Inskipp *et al.* (1996), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), Mann (1989), van Marle & Voous (1988), Marshall (1978), McGregor (1909-1910), Medway & Nisbet (1965), Medway & Wells (1976), Mees (1986), Mitsch (1987), Nash & Nash (1988), Parrott & Andrew (1996), duPont (1971), Riley (1938), Round (1988), Schönwetter (1964), Smythies (1957, 1981, 1986), Steinbacher (1949), Stresemann (1937), Thewlis, Duckworth *et al.* (1996), Thewlis, Timmins *et al.* (1998), Verheugt *et al.* (1993), Wells (1985, 1999), Wells & Medway (1976).

12. Sunda Frogmouth

Batrachostomus cornutus

French: Podarge cornu **German:** Sundafrschmaul **Spanish:** Podargo Cornudo
Other common names: Horned/Long-tailed Frogmouth

Taxonomy. *Podargus cornutus* Temminck, 1822, Bengkulu, Sumatra.

Formerly considered conspecific with *B. javensis* by some, but a combined study of vocalizations and museum specimens in 1978 confirmed earlier ideas that the two should be regarded as separate species. Recent suggestion that a population of small *Batrachostomus* in Palawan ("chasei") may be a race of present species appears to be without foundation, since *chasei* is best regarded as a synonym of *B. javensis affinis*. Two subspecies recognized.

Subspecies and Distribution.

B. c. cornutus (Temminck, 1822) - Sumatra, Bangka and Belitung to Borneo and Banggi I (off N Borneo).

B. c. longicaudatus Hoogerwerf, 1962 - Kangean Is (NE of Java).

Descriptive notes. 23-28 cm. Plumage coloration very variable, and much confusion in the literature over how much of the variation is attributable to sexual dichromatism and how much to polymorphism. Adult male has broad pale supercilium, pale collar across upper mantle, and prominent whitish oval spots on scapulars; underparts mottled, belly and flanks paler with dark spots and bars. Occurs as two colour morphs, with intermediates: black-and-white morph has upperparts blackish, finely freckled and vermiculated with whitish to pale buff; brown-and-buff morph similar in general pattern, but with the blackish areas replaced

by brown and the whitish areas replaced by pale buff. Adult female varies from rather plain, with much deep rufous on upperparts and rufous on underparts, to so heavily freckled as to resemble brown-and-buff morph of male. The only juvenile specimen seen, a female, had soft-textured plumage and coloration closest to that of most rufous variants of adult female, but with lighter upperparts and underparts. Race *longicaudatus* averages longer-tailed and thinner-billed, with less contrast in plumage. Voice. Territorial song, presumably of female, a descending series of "qwa" units, like "caw" of Large-billed Crow (*Corvus macrorhynchos*).

Habitat. Differs from congeners in occurring mainly in secondary forest or at forest edge; also reported in low riverside bushes and occasionally in mangroves and in village gardens; reported occurrence in (tobacco and) rubber plantations, in Sumatra, not definitely attributable to present species. Mostly found in lowlands, but ascends to 1000 m.

Food and Feeding. One stomach contained beetle remains. No further information available.

Breeding. Poorly known. Only data on season from Sumatra: an egg in Jun and a nestling in early May. Nest is a small rounded structure with shallow cup, built mainly of down, moss and small bark fragments, placed on horizontal branch. Clutch 1 egg; incubation and fledging periods, and roles of sexes in caring for eggs and young, undescribed.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Little recent information on its status, but probably the commonest of the smaller *Batrachostomus* in Borneo; only recent records from Sumatra are several from Way Kambas National Park. The species' preference for second growth suggests that it may be less at risk from loss of habitat than are its sympatric congeners that require primary rainforest.

Class AVES
Order CAPRIMULGIFORMES
Suborder CAPRIMULGI
Family NYCTIBIIDAE (POTOOS)

- Medium-sized nocturnal birds with large head, small body, long wings and tail, and very short legs.
- 21-58 cm.

- Neotropical.
- Forests, mainly humid.
- 1 genus, 7 species, 15 taxa.
- No species threatened; none extinct since 1600.

Systematics

The potoos are endemic to the Neotropics, where they are known from every mainland country except Chile, reaching their greatest diversity in the Amazonian lowlands. They are an ancient lineage and, based on the existence of a European fossil, apparently were once more widespread than at present. The oldest fossil, a single leg bone of the extinct species *Euronyctibius kurochikini*, is from France and is at least 25 million years old, dating from the Upper Eocene to the Upper Oligocene. By that time, the modern tropical caprimulgid families had already evolved. Modern potoo species probably existed well before the Pleistocene, from which period date the only other two fossils known, both identified as the Common Potoo (*Nyctibius griseus*), and both from within its modern distribution.

The family Nyctibiidae is a uniform and undisputedly monophyletic group within the order Caprimulgiformes. Various morphological and behavioural features distinguish potoos from the other families, such as the "toothed" bill, the lack of rectal bristles, and, as compared with most of the other families, the upright perching posture (see Morphological Aspects). The relationship of potoos to the other caprimulgid families, however, is less evident. In their upright posture, they resemble frogmouths (Podargidae) of the Old World, with which they have sometimes been allied, along at times with the Oilbird (Steatornithidae). More often, though, the nightjars (Caprimulgidae) are thought to be potoos' closest relatives. In fact, the earliest potoo species discovered were originally described in the genus *Caprimulgus*. A recent molecular study placed the potoos as sister to a group comprised of the nightjars (including the *Eurostopodus* eared-nightjars) and the owl-nightjars (Aegothelidae). In general, though, biochemical studies have found all the caprimulgid families to be highly genetically differentiated, probably a consequence of their great old age. The result is that the families have numerous unique characteristics, a few characteristics shared by all members of the order, and a seemingly random distribution of traits shared with one or another family that could be due as much to convergence over long periods of time as to genetic relatedness. This makes it difficult to establish with any certainty the relationships among the families.

The seven extant species of potoos all belong to the genus *Nyctibius*. The levels of genetic divergence among these species, however, may be the greatest in any single genus of birds, and are equal to or greater than those typically found among birds in

different genera or even families! This suggests that the species too are very old, once again hindering phylogenetic analyses. It is possible that this genetic differentiation, although not obviously reflected in morphological differences, will be acknowledged in the future by separating the most divergent forms into distinct genera.

Likewise within species, a lack of conspicuous geographical variation in morphology might mask strong genetic differentiation. Within a single subspecies of the Great Potoo (*Nyctibius grandis*), for example, genetic divergence between populations on opposite sides of the Andes is comparable to that among distinct potoo species. Thus, it is conceivable that future study will reveal the presence of unrecognized "cryptic species" of potoos. In Costa Rica, what was previously thought to be a single widespread race, *costaricensis*, of the Common Potoo actually contains two vocal types now recognized as belonging to distinct species, the Northern Potoo (*Nyctibius jamaicensis*) and the Common Potoo. Nevertheless, no consistently diagnostic morphological features have yet been identified to distinguish them (see Voice). On the other hand, in the Long-tailed Potoo (*Nyctibius aethereus*), two races, the nominate and *longicaudatus*, originally described as distinct species based on rather striking size and colour differences, are reported not to differ vocally. In this case, the vocal similarity between the two populations might be just another example of the conserved nature of potoo phenotypes over long periods of time.

Despite the conservative phenotypes, individual variability in potoo plumages is considerable, sometimes as much among individuals within a population as between supposedly distinct subspecies. This, coupled with a general shortage of data, due in large part to the difficulty of studying nocturnal birds, has further hindered progress in recognizing taxonomic limits and phylogenetic relationships. Many new taxa were described based on one or a few specimens and incomplete knowledge of species' distributions. Hence, a somewhat different-looking individual in a new part of a species' known range was interpreted as representing a new taxon, rather than as a previously undocumented variant within the normal range of variation, or as an extreme in a continuum of geographical variation. This is the case for the mainland Middle American subspecies of Northern Potoo, which on further study might prove to grade into one another over a continuous range. Similarly, the great individual colour variation and longitudinal size trends (see Morphological Aspects) in Great Potoos, may render the race *guatemalensis*

undiagnosable by morphology. However, if the Andes prove to be a clear barrier between genetically disparate forms, as already suggested, then the name *guatemalensis* may better be applied to the entire Great Potoo population west of the Andes through Middle America.

Another example of these problems is the currently invalidated subspecies *N. griseus cornutus*, originally described from Paraguay in 1817. As early as the 1920's, A. Wetmore recommended that *cornutus* be synonymized with nominate *griseus* (which itself had been overlooked in the literature for over a century), pointing out that the species' considerable individual variation in plumage colour is an obstacle to proper classification. Wetmore's suggestion was corroborated by subsequent study in Brazil by O. Pinto and colleagues and generally adopted in the Brazilian literature. Without any further evaluation and apparently overlooking Wetmore's work, however, the English-language literature maintained the taxon *cornutus* up to the present, applying the name to all *griseus* south of the River Amazon. A study by L. I. Davis even proposed that *cornutus* be elevated to full species rank based on vocalizations of a single individual in Peru. Even if the subtle distinctions of those songs represent an entire population, rather than simply the individual recorded, it is not clear that the Peruvian population would refer to typical *cornutus*, from Paraguay. Until thorough studies are conducted, *cornutus* can not be considered distinctive on the basis of either voice or morphology.

Molecular evidence suggests that Andean Potoo (*Nyctibius maculosus*) and the lowland White-winged Potoo (*Nyctibius leucopterus*) are most closely related, and that they share a common ancestor with the widespread Common Potoo. The phylogenetic relationship of the other species is not as clear. Based on similarity in vocalizations, one author suggested that the Northern Potoo, long considered conspecific with Common Potoo, is actually closer to the Great Potoo. This rather unlikely hypothesis has not been tested rigorously. The notable vocal similarity between Long-tailed and Andean Potoos could also be interpreted as indicating close relationship, although no such suggestion has been forwarded in the literature, and other evidence seems to argue against this interpretation. Much work remains on the evolutionary history and relationships of potoos.

Though in their characteristic sharply upright perching stance potoos resemble the frogmouths (Podargidae) of South-east Asia and Australasia, they seem to be most closely related to the nightjars (Caprimulgidae), but they have distinctive features of their own, such as a toothed bill with no adjacent bristles. There are complex inter-relationships of size, colour and song-type both within and between some potoo species. Thus, the Common Potoo is now separated from the Northern Potoo (*Nyctibius jamaicensis*), though they can be distinguished only by voice.

Patricia Fogden]

As recently as 1989, a new population of potoos was discovered in Amazonia. These birds closely resemble the White-winged Potoo, itself known only from two museum specimens collected in the nineteenth century, probably in Brazil's Atlantic rainforest. Research in progress has turned up this Amazonian form in widespread localities throughout the basin. Subtle but consistent differences between the Amazonian and Atlantic forms suggest that the Amazonian birds are distinct, and they will receive their own designation, at least as a separate subspecies. However, considering how in potoos even small phenotypic differences can correspond to enormous genetic divergence, this Amazonian bird might best be considered a new species.

Morphological Aspects

Potoos are strange-looking birds. Structurally, they are very much like large, upright nightjars. Their vertical posture lends them a resemblance to frogmouths, which, however, are stockier and have much heavier bills. They also look remarkably like owls, especially when not in their defensive "freezing" posture (see General Habits). Potoos have a disproportionately big head and long wings and tail, relative to their small body and very short legs. The head is dominated by huge eyes and an enormously wide, frog-like mouth, with the bill so short that it barely projects out of the fluffy face. Despite the large head, the brain is tiny, in the smaller species merely the size of a peanut or of a hummingbird's brain. The potoo body is also deceptively small, as attested by their light weight for their size. In a perched bird, more than half of its length, made up entirely of the wings and tail, extends below the perch. In effect, the potoo as a machine is little more than a flying mouth and eyes. Because potoos are rarely observed in the wild, their behaviour is poorly known, and in many cases the connection between their unusual morphology and its function in their lives is a matter of speculation.

All potoo species share the same general morphology, including a number of distinguishing features. The delicate bill is much like that of nightjars, having a very short culmen and wide gape; however, the cutting edge of the maxilla (upper mandible) has a unique, tooth-like projection positioned well to either side of the tip of the bill, which may have a role in foraging (see Food and Feeding). Unlike the similar-looking nightjars, potoos do not have rictal bristles, that is, bristles at the corners of their mouth. They do, however, have some thin bristles emanating from the loreal region between the eye and nostril. Bristles at the base of the bill are also found in many unrelated bird species, especially those that take large or flying insects by capturing them directly in their bills, such as puffbirds (Bucconidae), some wood-warblers (Parulidae), and most tyrant-flycatchers (Tyrannidae). In general, it is believed that these help in detecting or capturing flying prey, or in protecting the predator's eyes.

Potoo eyes are very large, even relatively larger than in the other caprimulgiforms, and at night they reflect a strong red or orange glow in the beam of a flashlight. Large eyes and widely dilating pupils (the reason they reflect so much light in the dark) are an adaptation to life at night and are found throughout the order Caprimulgiformes, as well as in other nocturnal animals, including frogs and cats. The position of their eyes, bulging upward and outward at the sides of the head, enables potoos to see in most directions without turning. Most potoo species have a bright yellow iris; however, the iris of the Rufous Potoo (*Nyctibius bracteatus*) has a dark wedge in the lower portion, and the Great Potoo's is brown. The upper eyelids of all potoos have two or three small folds along their edge, which create notches or slits. The result is that, even when their eyes are closed, potoos have small "peek-holes", through which they can probably detect motion. This so-called "magic eye" probably helps them maintain their camouflage by permitting them to see during the day without conspicuously opening their enormous eyes.

The feet are small and weak, and are barely used for anything other than perching quietly on branches. Potoos are not known to capture prey with their feet or to walk or even to move much on their perches, and only exceptionally will they land on the ground. The underside of their toes has a thick, fleshy pad,

One of the camouflage classics of the animal world: this Great Potoo seemingly turns itself into the thick broken-off stump of a tree branch, as it passes away the daylight hours in peaceful inactivity. For potoos, the roost-site is typically high in a tree in the shadow of the crown, though, depending on local conditions, a bird may spend the day in the full glare of the sun, even in a quite exposed and conspicuous spot.

no doubt an adaptation to their sedentary, perched lifestyle. As in most other caprimulgid families, they lack the unique, comb-like middle claw of nightjars, which is presumably used in preening in that family. Potoos have powder-down patches on the breast and sides and have an oil-gland, both of which are related to preening, although this has rarely been observed in this family.

Potoos' flight is silent and manoeuvrable. In addition to being long, their wings are relatively broad and round-tipped, providing considerable lift for the birds' light weight. Potoos beat their wings stiffly and buoyantly, much like nightjars or enormous butterflies. They often glide on flat wings, the tips held slightly downward, like owls. In direct flight or glides, the long tail is held closed; but on landing or when abruptly changing direction in pursuit of prey, they spread the tail wide open. Broad, fluffy feathers with aftershafts contribute to their noiseless flight.

The differences among potoo species are mostly in size and coloration. The largest, the Great Potoo, at about 500-600 g, is the size of a big owl, whereas the diminutive Rufous Potoo weighs only about 50 g, roughly the size of a large martin. Despite this size range, overall body proportions are similar among the species. The exceptions are the two largest species. Great Potoos are relatively bulky and heavy-bodied, whereas Long-tailed Potoos have disproportionately long tails. Size variation within the widespread species, such as the Great Potoo and the Northern-Common Potoo superspecies, tends to follow Bergmann's Rule, with size increasing with distance from the equator, even within their entirely tropical distribution.

Most species have complex and cryptic plumage patterns of browns and greys, with extensive fine barring, streaking and mottling, much like that found throughout Caprimulgiformes. Typically, they are somewhat paler below than above, with a pale throat and a dark-barred tail. Several species have variably pale secondary coverts, creating a wing patch, which is most developed in the White-winged Potoo. Also, most species have variable densities and distribution of dark blotches on the breast, sometimes giving the impression of a breastband. The Great Potoo is the palest and most variable species; some individuals are nearly white. The exception to the typical potoo plumage pattern is the Rufous Potoo, which is a nearly uniform bright rufous throughout, interrupted only by black-bordered white spots on its body feathers. It is remarkably similar in plumage to the Oilbird

(*Steatornis caripensis*) and to the red colour morph of some nightjars and owlet-nightjars. Reddish tones are found to varying extents in the feathers of the other, predominantly brown and grey species, as well. It has been suggested that potoos have red and grey colour morphs, as in some other caprimulgiforms and owls. However, their considerable intraspecific plumage variability does not seem to fall neatly into distinct colour morphs. Although potoos have no described sexual dimorphism in size or coloration, some of their individual plumage variation may prove to be associated with age or sex.

As might be expected in birds that depend on camouflage for defence, potoo plumage colour appears to be subject to strong natural selection. Coloration within widespread species is often paler in populations in drier environments, such as Caribbean versus mainland Northern Potoos, and so seems to obey Gloger's Rule.

Juvenile plumage is mostly undescribed, but all the species in which the juvenile is known show distinctive juvenile plumages. In several cases they are much paler than the adult form, sometimes nearly pure white. Juvenile Rufous Potoos, by contrast, are darker and browner than adults, with markings more typical of the adults of other potoo species.

Habitat

Potoos are forest birds, all species occurring in dense humid forest, although some also occur in drier forest or in patches of trees amidst lower vegetation. All five lowland Amazonian species can be found in the same *terra firme* woods, whereas in seasonally flooded *várzea* usually only Common and Great Potoos are found. Long-tailed, White-winged and Rufous Potoos all seem to be patchily distributed throughout Amazonian rainforest. This could be due to subtly differing habitat preferences not yet detected or simply to lack of observations. The Common Potoo is especially flexible in its habitat selection, inhabiting rainforest, dry forests, *cerrado*, mangroves, partially disturbed areas, and tall second growth. Its sister species, the Northern Potoo, is also fairly flexible, occurring in humid and dry forests, as well as plantations. All species are limited to the tropical lowlands, except the Andean Potoo, which occurs in cloudforest along a fairly narrow elevational belt in the Andes.

The perfection of a potoo's camouflage must surely make a major contribution towards keeping it secure from the vast majority of its potential daytime predators, looking as it does like dry, cracked bark with a spattering of lichens. The Great Potoo is more variable in its plumage even than are other members of the family, and some individuals can be almost white; such variation may be linked to the habitats occupied by the different populations, as certainly seems to be the case with the Northern Potoo (*Nyctibius jamaicensis*). When roosting in the full sun, a potoo will sometimes sit with the head turned away from the direction of the sun's rays and the bill held very slightly open, as it relieves itself from heat stress with some surreptitious panting. Otherwise, it is quite normal for the roosting bird to make virtually no other movements for hours on end.

Most species occur in the canopy, foraging from exposed perches, especially bare snags, in the tops of tall trees. Because they forage in the open air, several species will venture out along forest edges, sometimes even into pastures, where they will perch on fenceposts. Great, Northern and Common Potoos are the species most regularly found in open habitats at night; however, they are rarely far from forest. The most strictly forest-based species is the Rufous Potoo: it typically stays in the understorey and middle storey of tall rainforest, sometimes less than a metre off the ground, although it too will forage up in the canopy and at the edge of treefall gaps. The Long-tailed Potoo also forages in the shady interior of rainforest, but seems just as at home at edges and even in the open near forest. The White-winged Potoo, on the other hand, stays strictly in the canopy of tall forest, unless at an edge, where it might drop lower accompanying the height of the tallest vegetation.

During the day, potoos typically roost high in trees, but usually in the shadow of the tree crown, along relatively heavy, bare branches where they look like stubs. Potoos have been reported roosting atop telephone poles, and the Great Potoo is regularly seen during the day on exposed canopy branches at river edges, sometimes in full sun. Nest-sites (see Breeding) are like day roosts, usually on branches that are at least as thick as the bird.

General Habits

Potoos are nocturnal and, under normal conditions, will not fly during the day. They spend their days perched still in the trees, upright on horizontal branches or at the tips of broken stubs, sometimes in exposed and conspicuous places. While resting, a bird has its eyes closed, its head hunkered on its shoulders, and its bill held horizontal so that it is almost unnoticeable, the loose body feathers masking anything birdlike in the potoo's form. With its cryptic plumage, the effect is of a dead stump, a lump of fungus, or a termite mound in a tree. If disturbed, perhaps detecting movement through the small slits in its eyelids, it assumes a "freezing" posture with the body elongated, feathers pressed down flat, neck upstretched, and bill held nearly vertically overhead, with the suggestion of a small "horn" erected over each eye. In this pose, it resembles a broken branch even more strongly. This is the posture most often illustrated, because it is the way most potoos are seen. The transition from resting to freezing is so smooth and gradual that, although it may occur in front of an observer, he will usually not detect any movement.

Roosting potoos barely move all day long; hence, they are known in Mexico by such local names as *bienparado* or "perfectly still", and *pájaro estaca* or "wooden stake bird". Occasionally one will stretch its wings, lean forward horizontally as if to stretch, or scratch its head with the foot brought over the wing. Individuals perched in the sun often sit with the bill open slightly, inconspicuously panting, with the head turned away from the sun. Because they do not need to open their big eyes to see movement, they rarely do so during the day. In fact, they rely so heavily on their camouflage that they can sometimes be approached and captured by hand before they will fly. A captured potoo will suddenly become animated, uttering a grotesque, croaking scream with its enormous mouth held open wide. Passing hawks may cause a potoo to "freeze", suggesting that hawks prey on potoos. For the most part, though, potoos are probably rarely bothered because their camouflage is so effective. Their cryptic plumage blends nearly perfectly with the colour and pattern of lichen-covered tree bark. Even the very differently coloured Rufous Potoo is beautifully camouflaged, its reddish tone blending with the colour of dead leaves, and its bright white spots like the flecks of sunlight that dapple the dark rainforest interior.

At night potoos do not seem particularly concerned with being cryptic. While scanning for prey from a perch, they look remarkably owl-like, the head turning rapidly from side to side, covering nearly 360°, or suddenly tipping up to follow the movements of some potential prey. With the head in its natural horizontal position, the eyes are directed slightly upwards, so objects above the horizontal are seen without effort. Potoos sing from the same exposed perches from which they forage, and are highly territorial, responding aggressively to playback of their songs.

The manner in which potoos can alter their appearance when perched is quite striking. The classic thin, inanimate-looking cryptic pose of this Great Potoo, with feathers sleeked flat and bill pointing high, in the past often erroneously interpreted as a sleeping posture, is in fact adopted only when the bird is disturbed; inevitably, this is the posture in which birds are most commonly seen. In contrast, a bird resting normally at the roost, or when active and hunting at night, has its feathers looser and relaxed, its head sunk into its shoulders, and its bill held level. The enormous eyes are not normally opened fully during the daytime, but this hunting Common Potoo clearly shows how the globular eyes bulge outwards and upwards, giving their owner an ample field of vision. Most species, like this one, have a bright yellow iris.

The main feeding technique used by potoos is that of a large, nocturnal and highly arboreal flycatcher. They make short sallying flights from an open perch, usually to take flying prey, though they will also fly to pick items off vegetation. Catching prey on the ground is evidently rare at best. This Great Potoo, perched on a snag in open woodland, can be seen in a typical alert foraging posture. Birds will also hunt in dense forest, where they are sometimes required to swoop acrobatically on their long wings.

Next to nothing is known about potoo hygiene and maintenance. In a modest concession to cleanliness, a bird will lean forward and raise its tail slightly to defecate at an angle, avoiding staining the nest-site or day roost. The only preening observed has been an infrequent and rather lethargic bill primping of the breast feathers during the day, performed with the eyes characteristically closed. Reminiscent of the fur of sloths, the tail of some species can have a green stain on its tip or underside, apparently due to moss or algae growing on the feathers. Potoos are host to their own unique genera of parasitic feather mites (*Nyctibiolichus*) and lice (*Nyctibicola*).

As far as known, potoos always roost solitarily. At night, it is not uncommon to hear two singing birds in the same general area, quite possibly members of a pair. However, pair members are rarely seen together and then only briefly, even near the nest. In Trinidad, where the Common Potoo has unusually dense populations in the mangroves, and many individuals can be seen in a short period at nightfall, up to three birds have been seen foraging within sight of each other.

Because they are nocturnal, cryptic in plumage and behaviour, and live in the canopy of dense and remote forests, potoos are among the least studied of birds. What little is known about them is based mostly on museum specimens, themselves rare in collections, and on few observations of few species. Much of the information included here is from recent, unpublished observations by the present author and colleagues. Current fieldwork in the Neotropics is gradually improving our understanding, especially now that potoo voices are better known, making the birds easier to detect and locate.

Voice

Much more often heard than seen, potoos are best known by their haunting songs. Some species have more or less pure-toned songs sounding like whistles; others have a rougher, raspy, or even croaking quality. In Trinidad, the Common Potoo is called the "Poor-me-one", a more or less onomatopoeic interpretation of its song, meaning "Poor me, all alone". This is the most plaintively beautiful of all potoo songs. The experience of hearing a Common Potoo in a rainforest bathed in moonlight is one that marks its listener for life. The combination of eerie melancholy and mys-

tery surrounding potoos make hearing their song one of the quintessential Neotropical experiences.

Potoos sing most on moonlit nights, especially within a few days of the full moon, and at twilight. Apparently, the dim light conditions at these times are what most stimulate song. As with most birds, their song is a form of territorial advertisement. Playing back a tape recording or imitating a singing bird will usually bring that bird in close, even from a considerable distance, and is one of the few dependable ways of seeing a potoo. In response to playback, birds may sing continuously from a perch almost directly overhead and sometimes utter short calls while apparently searching for their imagined rival. Call notes are also given by both members of a pair to establish contact. Both males and females sing, although females may utter a weaker version of typical song, and males normally respond more aggressively to playback.

Vocalizations play an important part in potoo taxonomy (see Systematics), sometimes even serving as the sole basis for distinguishing species, as is the case with Northern and Common Potoos. Populations that were for a long time considered a single species occurring throughout the Neotropics are now recognized as containing two distinct vocal types, one in northern Middle America, and the other adjacent to it in southern Middle America and throughout tropical South America. In Costa Rica, where both vocal types occur and seem to segregate geographically, no distinct morphological differences have been found that correspond with the abrupt vocal shift. The differences in song are assumed to represent genetically distinct populations, not local dialects that are due to song learning from parents or neighbours. Also, it is assumed that representatives of the different song groups, if they came into contact, would treat each other as distinct species, not reacting to songs of the other type and not interbreeding. Although these are all probably reasonable assumptions, none has yet been tested.

The extent to which vocal differences represent populational genetic differences is not always clear. Striking differences in song helped to confirm the distinct species status of Andean and White-winged Potoos. On the other hand, without strong pressure from natural selection, voice could be subject to the same conservatism as found in potoo morphology. Thus, a lack of vocal distinction between geographically isolated populations may not signify a lack of genetic divergence. In the case of the Long-tailed Potoo, the Amazonian and Atlantic forest subspecies differ more morphologically than do other

The nest of this Common Potoo is in a typical site, being no more than the knot-hole of a broken-off branch. As rather large birds breeding in exposed sites, and with a nesting period lasting about three months in all, camouflage and cryptic behaviour are even more important to potoos when they are breeding than at other times. Thus all activity at the nest is minimized: the sitting adult perches on the edge of its nest, with its belly feathers fluffed forward over the egg or chick; nest change-overs take place only twice a day; and the chick is fed just a few times during the night.

[*Nyctibius griseus*, Cuyabeno Faunal Production Reserve, eastern Ecuador. Photo: François Savigny/ BBC Natural History Unit]

potoo subspecies, but are reported not to differ vocally. Also, it is crucial to distinguish the variations in voice produced by a single individual, or among individuals or between sexes within a species, from actual population genetic differences. The subtle vocal differences suggested by L. I. Davis to indicate the full species status of both *N. jamaicensis abbotti* and *N. griseus cornutus* need further study, to establish that they are not merely the product of single or few unusual individuals or of particular behavioural contexts.

Considerable progress has been made recently in identifying the mysterious sounds of night birds. The songs of all currently recognized potoo species are known. Nevertheless, there are numerous Neotropical night sounds reported, the source of which has never been identified; some of these may be potoo vocalizations. Also, potoo vocal repertoires are probably more varied than is presently known. Distinctive vocalizations associated with courtship, disturbance, and chick begging calls have been recorded in only a few species, but probably all species have them. Within any species, very little has been documented in the way of geographical variation in songs, and complicated cases, like that of the Northern and Common Potoos, require much more detailed study. With the White-winged Potoo, only the voice of the Amazonian form is known; birds of the population in Brazil's Atlantic forest have never been heard knowingly, nor has any individual been seen alive. As has been found in other potoo species, morphological resemblance is no guarantee of vocal similarity.

Food and Feeding

Potoos eat flying insects. They forage during the crepuscular period and at night, mostly by sallying from exposed perches much in the manner of many Tyrannidae: they fly up into the air to intercept and catch their prey one by one, returning to the same or another perch between attacks. This is also similar to the foraging of nightjars, except that potoos initiate their sallies from arboreal perches, never from the ground. A typical sally may range from less than one to several metres and is usually directed upward or horizontally on a more or less straight path. In aerial pursuit of prey, potoos can be surprisingly acrobatic on their long wings, even in dense forest. A Long-tailed Potoo, one of the largest species, was observed chasing flying termites in the rainforest understorey by making short sallies, turning abruptly to return to

its perch or suddenly twisting and changing directions in pursuit; yet it never even brushed its great wings or tail against the crowded vegetation or made a single sound.

Potoos will sometimes fly to vegetation to pluck off a perched insect. Unlike frogmouths and owlet-nightjars, potoos apparently do not drop to the ground after prey. A large katydid, being chased by a Great Potoo, closed its wings and fell straight to the ground, at which point the predator stopped its chase and, turning around abruptly in mid-air, returned to its high perch; from there, it completely ignored the katydid, although the insect remained on the ground in an open and conspicuous spot. The presence of beetle larvae and pieces of wood in the diet of one Northern Potoo suggests that potoos may occasionally investigate rotten trunks, although how they exploit this substrate, from the air or perched, is not known.

The commonest prey are beetles, including fireflies. Potoos also eat other night-flying insects, especially ones that fly slowly on fairly straight or predictable paths, including moths, true bugs, large orthopterans, and neuropterans. Flying termites constitute a favourite food during one of their hatches, when they are consumed in large quantities by potoos, as they are by most rainforest insectivores. Although their disproportionately large mouths enable potoos to take large prey, the bulk of their diet is composed of remarkably small items, and it is often impossible for an observer to detect the target of a given foraging attempt.

Potoos engulf their prey whole on the wing and are not known to beat it or to manipulate it in any way with their feet. The "teeth" on a potoo's bill may help to secure or break the wings of large prey, if they extend beyond the potoo's gaping mouth when captured. It is difficult to imagine how potoos swallow hard-bodied prey like beetles, which often have horns, spines, powerful mandibles and claws, without hurting themselves. Their jaws are too weak and the bill too delicate to crush such prey. However, the soft mouth and throat are lined with a tough and flexible skin that probably helps immobilize prey. Remarkably, a White-collared Seedeater (*Sporophila torqueola*) was found in the stomach of a Northern Potoo! Presumably, the little bird was taken after being flushed off its perch at night.

Although they rarely have any fat in the furcula or elsewhere on the body, potoos typically have large amounts of fat in the abdominal cavity. The reason for this is unknown. Perhaps the fat is a natural by-product of digesting their particular prey. It could

also be an adaptation for surviving short periods without food, such as rainy nights when few insects are flying or during the new moon when nocturnal visibility may be limited to dawn and dusk periods. Supplementing diet from fat stores might allow reduced foraging frequency, which could be advantageous to a bird whose primary form of defence is to remain still and camouflaged, especially during the prolonged nesting season (see Breeding).

Breeding

Considering how little is known about potoos in general, a surprising amount has been published on their nesting. Because a potoo nest, once found, is easy to observe, some accounts involve prolonged and detailed description. The total number of nests studied still amounts to only a handful, mostly of Common and Great Potoos, but the similarities among them (including observations of a Rufous Potoo nest, as yet unpublished) suggest that the following description may be generalized to all potoos.

Potoos are monogamous, both parents participating actively throughout the nesting period. Although the duration of the pair-bond is not known, nonetheless given the long duration of nesting and the fact that individual potoos maintain long-term territories, it is likely that pairs stay together on a long-term basis. On one occasion, a female apparently solicited mating by uttering an unusual vocalization, immediately attracting the male to her perch where they briefly copulated. Nothing is known about selection of the nest-site: how or when the site is chosen, by which member of the pair, or whether nest-site plays a role in mate selection or in territory location and size.

Potoos do not build a nest, but rather choose a natural depression in a tree, to which they apparently add no nesting material whatsoever. Typically, the nest is in the scar left on a branch or trunk where an upward-pointing branch died and fell off, or on top of a broken stub. One nest was in the tip of a slender dead palm stem, where the natural segmentation of the stem (as in bamboo) left a hollow just large enough for the single egg. The depression must be shallow enough so that part of the egg sits above it and can be incubated, but deep enough so the egg will not roll out. Although the female surely lays her egg directly in the nest, the spot appears so precarious that it has even been suggested that the egg is laid elsewhere and later carried to the nest in the adult's capacious mouth! The egg appears not to be stuck to the nest in any way, as is sometimes supposed, but also is not known to be turned or manipulated at all by the adults. Its shape is elliptical, averaging roughly 1.4 times longer than wide, and with one end broader than the other. Overall coloration is white with dark purplish-brown spots, most densely distributed near the broad end. Egg size for the smallest species is not known, but those eggs described to date range from roughly 36 x 26 mm for the smallest Common Potoo egg to about 52 x 38 mm in the Great Potoo. Clutch size, as far as known, is always one egg.

Both parents participate in nesting. It is impossible to identify the sex of the parents by their outward appearance and usually is hard even to distinguish one parent from the other. Nevertheless, specimens collected on nests during the day have turned out to be males. The parent that incubates in the day, presumably the male, stays all day without leaving the nest. At nightfall and before dawn, the parents switch roles. Sometimes the switch is made seamlessly, and on other occasions there can be a brief period when no adult attends the nest, during which time both parents are probably foraging. This timing may depend in part on whether the arriving bird has eaten enough yet when the other decides to leave, and on whether weather conditions permit the bird on duty to leave before the other settles in. In any case, the parents often give soft calls during this period, so vocal as well as visual cues may alert the sitting parent to the presence of the other.

The incubating or brooding parent perches at the edge of the nest in a normal resting position giving no sign that it is on a nest. The egg, and later the chick, disappears under the belly feathers of the adult. Normally the chick and brooding adult face in the same direction, and only after the chick is fairly large does it begin to become visible, poking out among the adult's breast feathers. Once the nestling has grown feathers covering its body,

the adults leave it for longer periods and take turns brooding through the night. Eventually, when the chick is too big for an adult to perch with it comfortably, the adults stop brooding. At this point, they may perch near the chick in the same tree or elsewhere out of sight, presumably nearby.

The chick is fed only a few times during the night, mostly just after dusk and before dawn. The parents feed by regurgitation, landing at the nest, looking upward while choking up food, and then tipping the head down to the nestling with open mouth, into which the chick lunges. Each arrival of an adult at the nest usually results in one or at most three feedings. Feeding frequency decreases as the chick grows, although possibly the quantity of food delivered increases.

Camouflage and inconspicuousness are the rule in potoo nesting. Infrequent feedings, limited activity, and infrequent vocalizing at the nest are probably adaptations to limit drawing attention. One Common Potoo was reported singing repeatedly from the nest, but in other cases singing was only heard away from the nest. Anything larger than a small bird near the nest may cause the adult to assume its alarm posture. Only as a last resort in defence of its young will a nesting adult potoo give up its dead stump imitation to frighten off a potential predator. If approached too close, first it will open its huge, bulging eyes and then suddenly lunge, snapping open-mouthed. Although unlikely to inflict any damage with its strike, this is a startling and intimidating display, especially coming from an object that moments before looked like a stick! Adults flushed from the nest during the day have given distraction displays, feigning a broken wing and sometimes even falling to the ground. A pair near their nest at night vocalized conspicuously and took turns flying short distances until they had led the observer several hundred metres through the woods away from the nest, at which point they became silent and flew off.

As the chick grows, it increasingly gives begging calls; these are single, buzzy notes and are hard to locate. At a fairly young age, the developing chick begins to assume the freezing posture when disturbed. If approached closely by an intruder, however, it will also lunge at it with open bill in mock strikes. Otherwise, the chick is extremely still, looking more like a lump of fungus

The Great Potoo chick sits tight in its knot-hole nest for some two months before it finally fledges. While peacefully perched, both adults and young will perform light rocking movements, perhaps in order to take a little exercise in a most inconspicuous way. The chick soon starts to adopt the adult's stiff upright posture if there is a source of danger or disturbance present, but, surprisingly, the near-white juvenile plumage of this species does not seem well suited to the crypsis on which it appears to depend.

[*Nyctibius grandis grandis*, gallery forest of the llanos, central Venezuela. Photo: Russell Thorstrom]

than a bird. Both nesting adults and nestlings have been observed to make a gentle rocking motion periodically at the nest. This may be a way to increase circulation without drawing attention. Eventually, shortly before fledging, the chick begins sessions of wing beating, mostly at night. Newly fledged young will perch near the nest for some days after their first flight, but seem to make no effort to return to their long-held position at the nest.

The incubation period can last at least one month and the fledging period over two more months after hatching. This is one of the longest nesting periods of any landbird. Even after leaving the nest, the fledgling is not adult size and continues to beg and be fed by the adults. This slow development, with limited activity at the nest shared by both parents invested in a single chick over a prolonged period, is consistent with the economy of movement characteristic of potoos, and attests to the success of their cryptic behaviour. A few cases of egg loss or chick disappearance and subsequent nest abandonment have been reported, but the presumed nest predator was not observed.

Nesting seasonality in potoos is poorly understood. Reports of nesting at the same location two and three years in a row at the same time of year suggest that nesting is seasonal and annual. Across the geographical ranges of Great and Common Potoos, however, these species appear not to be consistent in the time of year or season (wet as opposed to dry) during which they nest. A possibility worth examining is that factors such as the amount of annual rainfall and seasonal abundance of insect prey are related to nesting seasonality. In areas of very heavy rainfall, prolonged and forceful rains in the wet season may endanger chick survival and decrease available foraging time for adults, making dry season nesting preferable. On the other hand, insect abundances are usually greater at the start of the rains, when nesting might be expected to occur in drier regions, where the rainy season is milder. Multiple brooding is not known in potoos, and the length of the nesting period makes their producing more than one brood per year seem unlikely, especially if nesting is indeed seasonal.

The nest itself is apparently not used as a roosting site outside the nesting season, either by the adults or by the chick once it has fledged. Repeated nesting at the same site, however, sug-

gests that a good nest-site, although requiring no particular construction effort by the parents, may be hard to find. Considering that nest-sites are typically where some part of a tree has been damaged, either at a broken vertical stub or at the knot-hole where a branch has fallen off completely, such sites are probably often subject to rotting and may be short-lived. After one year, the dead and broken-topped palm stem where a Rufous Potoo had nested was so decomposed and fragile that it could not sustain even a gentle touch without breaking, much less the comings and goings for months of a pair of nesting birds. Despite not adding any material to a nest-site to improve its quality, adults seem to choose remarkably consistent kinds of locations for nesting. Given the rather exact specifications a nest-site must meet and the site's probably brief useful lifespan, the availability of nest-sites could be a limiting factor in potoo population density.

Movements

As far as is known, all potoo species are sedentary. In most cases, they probably maintain permanent territories all year round. Potoos can be found consistently at known sites for years, often at the same favourite perches. On the other hand, the Common Potoo in Costa Rica is known to occur only sporadically at certain sites. This may reflect local variability in resource quality or unstable population density near the limit of the species' range, rather than any large-scale movements.

Home range size is unknown. It may simply be noted that playback of vocalizations can attract a singing individual over several hundred metres. Post-fledging dispersal of young potoos from natal territories is, as with most birds, entirely undescribed.

Presumed vagrancy has been reported three times in potoos. There are two records of Northern Potoos from the tiny Caribbean islands of Mona and Desecheo, west of Puerto Rico; the nearest resident population is in Hispaniola, roughly 100 km away over open sea. Whether those vagrant birds arrived under their own power or were assisted by ships, as suggested by the following case, is a matter for speculation. A bird identified as a Common Potoo was seen flying around a ship sailing through the Panama Canal at dusk. As the ship pulled into harbour in Florida several days later, the bird was seen again, circling the ship before flying off in the direction of the mainland.

Relationship with Man

Potoos have fascinated man mostly for their mysteriousness. Even in their normally dry, technical writing, ornithologists often wax poetical and romantic on the subject of potoos. A. F. Skutch wrote that potoo calls "stir the imagination" and quoted lines from the poet Shelley. S. L. Hilty and W. L. Brown, in a field guide, described potoos as "so poorly known they seem more fiction than substance, their gruff or wailing cries ghostly delusions of the dim nocturnal world they inhabit". Although the genus name *Nyctibius*, meaning active or hunting at night, is not especially inspired, the choice of *aethereus* ("ethereal") for the Long-tailed Potoo is more representative of people's reactions to potoos. In parts of rural Colombia, potoos are called *mira para el cielo*, meaning "looks at the sky".

Local peoples in the range of potoos sometimes misidentify the familiar night voices of potoos as other animals. The voice of the Common Potoo is attributed to a sloth in some places, elsewhere to the pygmy anteater (*Cyclopes didactylus*). In the Brazilian Amazon, the song of the White-winged Potoo is often thought to be given by the *curupira*, a mythical forest spirit that protects animals from hunters.

Potoos, even when recognized as such, are surrounded by legend. The Common Potoo, in Brazil called *mãe-da-lua* ("mother of the moon") or *urutau*, is often believed to be the reincarnation of one of a pair of separated, widowed, or unrequited lovers whose sad lament is the bird's melancholy song. The songs of other species often inspire fear, and that of the Great Potoo is sometimes considered a sign of bad luck or impending death. For reasons unknown, potoo feathers have sometimes been attributed the power

The large size and long wings and tail of the Long-tailed Potoo make it an unlikely, if effective, flycatching species of dense forest interiors, as well as of more open woodland. Though not in danger on a global scale, as a species of primary forest it is locally threatened wherever such habitat comes under pressure, as for example in the Atlantic coastal forest of central South America. An adaptation of potoos which appears to be related to roosting is the presence of two or three notches which form peep-holes in the bird's upper eyelid: these may allow the bird to see approaching danger without having to risk opening its large and conspicuous eyes.

[*Nyctibius aethereus longicaudatus*, Amazonian region of Ecuador.
Photo: Russell Thorstrom]

to insure chastity. In rural Brazil, a potoo used to be killed and skinned for use in a ceremony intended to ward off seduction. Daughters at the beginning of puberty were made to sit on the potoo skin for three days while receiving worldly advice from their elders. More recently, and perhaps still to this day, potoo feathers were simply swept over the legs and hammock of the maiden to be protected or the bride whose fidelity was to be guaranteed. This power of potoo feathers, or perhaps merely their decorative value, may explain their occasional use in the ornamental garments of Amazonian Indians, including a necklace from Brazil made entirely of potoo feathers of several species.

Throughout the range of potoos, people living by subsistence will eat virtually any animal, and there are occasional reports of people eating potoos. However, potoos offer relatively little meat for their size and do not appear to be especially prized.

Status and Conservation

Potoos are extremely inconspicuous, appear to have few natural predators, and are not directly persecuted by man. On the other hand, they are not abundant anywhere, usually occur at low densities, and, for the most part at least, appear to be sedentary. These characteristics make them naturally vulnerable to the onslaught of human-caused habitat destruction. They are only as threatened as the forest habitats they occupy. Unfortunately, forests throughout the Neotropics are under constant assault from logging and agriculture, from governmental development projects, and from the ever-increasing numbers of landless poor. The first step of modern human expansion into areas of natural habitats continues to be deforestation or burning, resulting in what is often permanent unsuitability of those areas for continued occupation by native species.

No potoo species is currently listed as threatened, but several deserve special attention. The White-winged Potoo, although widespread in Amazonia, continues to be entirely unknown in life in the Atlantic forest, since it was first found there about 180 years ago. The Atlantic forest population, which is distinct from the Amazonian and may even be a separate species, if not extinct is probably limited to tiny patches of remnant forest. Before its near-total deforestation, the Atlantic forest was a heterogeneous

area composed of many different forest types, so it cannot be assumed that this species occurred throughout the entire region. Nevertheless, all areas should be searched intensively. The region from which it was originally described, presumably between the cities of Vitória da Conquista and Salvador in the Brazilian state of Bahia, is now dominated by cacao plantations. These plantations have historically left the largest forest trees intact, while replacing the understorey with plantations of cacao. It is possible that this potoo persists in the canopy of these areas, as do a number of other species with Amazonian affinities. Unfortunately, a recent blight affecting cacao plantations has caused many growers to switch to other activities, cutting down the remaining tall trees on their lands. Thus, the Atlantic forest's form of the White-winged Potoo should really be considered highly endangered, possibly extinct.

Similarly, the Atlantic forest population of Long-tailed Potoo is quite distinct from equatorial forms and may deserve recognition as a separate species. Although known from widespread localities, it appears to be rare and is probably quite limited in its current distribution. As with the entire Atlantic forest fauna, these birds must be vigorously protected. The Chocó form of Long-tailed Potoo, which is virtually unknown in life, and the Andean Potoo, which occurs in a fairly narrow elevational range on the humid slopes of the Andes, both have limited distributions and as such, although not in immediate danger, should be considered vulnerable. The Northern Potoo seems to be the most tolerant of man-altered habitats; nevertheless, this could simply be a result of the extreme lack of pristine environments in Middle America. Studies are needed to determine whether individuals found in disturbed areas represent breeding populations or mere stragglers from diminishing areas of preferred habitat.

Amazonian potoo species are in no immediate danger, because there are still huge expanses of primary forest in the Amazon. Nevertheless, habitat destruction in the Amazon continues apace, and it is only a matter of time before the situation becomes critical. Even in the most remote areas, due to international demand for timber, logging threatens pristine forests. Furthermore, recent recognition of the high levels of intraspecific genetic differentiation in potoos raises the possibility that traditional species limits do not account for real levels of potoo diversity. For this reason, populations within every major biogeographical sub-region, such as the Guianan shield and the major Amazonian interfluvia, should all be treated as potentially unique and should be protected. Because much the same may prove true for most of the Neotropical bird fauna, large and vigorously protected parks must be established in every habitat in every bioregion throughout the Neotropics. Seen from this regional perspective, even some Amazonian taxa are under immediate threat. For example, south-eastern Amazonia is already heavily deforested and contains few protected areas, although its birds are particularly poorly known.

In general, potoos probably do not require conservation measures directed specifically at them. Rather, habitat protection focused on preserving unique vegetation types and known areas of endemism for other bird species should be sufficient for potoo conservation as well. However, given their naturally low population densities, preserving large areas of continuous habitat may be necessary to maintain viable potoo populations. Forest management should include leaving some snags, which are important roosting, foraging and nesting sites for potoos, as well as for many other species. Finally, we must remember that potoos are among the world's least-known bird families. Ecological requirements, microhabitat preferences, distributional limits, and perhaps even new taxa of potoos, along with most details of their natural history, remain to be discovered.

General Bibliography

Atyeo (1979), Borrero (1974), Brodkorb (1971), Brumfield *et al.* (1997), Cannell (1986), Cascudo (1993), Cicchino (1989), Cleere (1998), Cohn-Haft (1998), Cracraft (1981), Davis (1978), Gonzaga (1981), Haverschmidt (1985), Hoff (1966), Mariaux & Braun (1996), Mourer-Chauviré (1988b), Olson & Steadman (1977), Peters (1940a), Ridgway (1914), Rose (1976), Sclater (1866a, 1866b), Sibley & Ahlquist (1990), Sibley & Monroe (1990, 1993), Sibley *et al.* (1988), Sick (1993, 1997), Stettenheim (1974), Wetmore (1918).

The Rufous Potoo is, in appearance, the most atypical member of the family. In addition to its small size, it has strikingly coloured plumage, somewhat resembling that of the Oilbird (*Steatornis caripensis*), and a peculiar dark wedge in the lower part of its iris. This bird is brooding a young chick on the only nest of the species so far known, atop a thin broken palm stem. This poorly known species is restricted to primary forest in lowland Amazonia, where it appears to be uncommon and perhaps locally distributed.

Genus *NYCTIBIUS* Vieillot, 1816

1. Great Potoo

Nyctibius grandis

French: Grand Ibijau **German:** Riesentagschläfer **Spanish:** Nictibio Grande
Other common names: Grand Potoo

Taxonomy. *Caprimulgus grandis* J. F. Gmelin, 1789, Cayenne. Currently accepted races are doubtfully valid, and perhaps represent merely extremes in broad geographical size trends and individual plumage variation. No taxonomically recognized variation in most of extensive range, despite great genetic divergence on opposite sides of Andes and possible population disjunction between Amazonia and Atlantic forest; may contain undescribed "cryptic" taxa. Two subspecies tentatively accepted.

Subspecies and Distribution.

N. g. guatemalensis Land & Schultz, 1963 - extreme S Mexico, Guatemala, and possibly Honduras. *N. g. grandis* (J. F. Gmelin, 1789) - Nicaragua to N South America, where mostly E of Andes throughout Amazonia to N Paraguay, and in SE Brazil; may occur locally between Amazonia and Atlantic forest regions.

Descriptive notes. 45-55 cm; 500-620 g. Largest and bulkiest potoo, looking relatively big-headed and owl-like. Palest and most variable species in overall colour, ranging from buffy-brown to nearly white; iris brown. Sexes alike. Juvenile nearly pure white. Races weakly defined, mostly based on subtle, perhaps clinal, differences in size. **VOICE.** Song a harsh, sickly sounding "KWAAAHW", sometimes followed quickly by a similar, shorter note; given mostly on moonlit nights and during the crepuscular period. A few other short, guttural or barking calls have been described.

Habitat.

Canopy of lowland forested habitats, including tropical rainforest (both *terra firme* and *várzea*); gallery forest in areas of savanna or *cerrado*; and forest patches, old second growth, and tree plantations in moderately disturbed areas. Found most often along rivers and lakes. At night regularly ventures into clearings or open areas near forest to forage. Roosts during the day in canopy of large, often bare trees, where resembles a large pale stump or termite nest.

Food and Feeding. Feeds on beetles (Coleoptera), large katydids and grasshoppers (Orthoptera), and other flying insects; may sometimes capture small bats. Forages at night with flycatcher-like sallies from exposed perches in forest canopy or posts in clearings. Each sally may be several metres long, directed at a single flying prey item; bird often returns to same perch after sally.

Breeding. Presumed monogamous. Nesting noted at various times of year with no described pattern of seasonality. Nest usually located at bend or along upper surface of heavy, horizontal or diagonal branch in canopy; no nesting material added; egg laid in knot-hole or natural depression just large enough to contain it. Lays 1 egg, white with dark brown, grey and lilac blotches, mostly near broad end. Male incubates during day; fledging period nearly two months.

Movements.

Presumed sedentary. **Status and Conservation.** Not globally threatened. Uncommon in closed-canopy forest; common or more easily detected in naturally semi-open habitat, such as in Venezuelan llanos. Supposed absence from the *cerrado* and *caatinga* regions of Brazil, between the great forested domains of Amazonia and the Atlantic coast, may be real or merely the result of undersampling in an area where densities may be naturally low, due to the scattered and local distribution of forest; possibly commoner and more widespread in this area before most of original forest cover was destroyed. Historical evidence suggests that the species once occupied Atlantic forest in NE Brazil, whence there have been no confirmed records in the last three centuries. Probably vulnerable in northern Central America and in SE Brazil, where little forest remains intact.

Bibliography. Cintra & Yamashita (1990), Clay *et al.* (1998), Davis (1978), Friedmann & Smith (1955), González-García (1993), Haverschmidt (1948, 1958c), Haverschmidt & Mees (1994), Hilty & Brown (1986), Howell & Webb (1995a), Land (1970), Land & Schultz (1963), Meyer de Schauensee & Phelps (1978), Monroe (1968), Ortiz & Carrión (1991), Penard & Penard (1910), Perry (1979), Perry & Slud (1980), Pinto (1938), Rangel-Salazar (1990), Rangel-Salazar & Vega-Rivera (1989), Rangel-Salazar *et al.* (1991), Remsen & Traylor (1989), Ridgely & Gwynne (1989), Ridgway (1914), Ruschi (1979), Rutgers & Norris (1972), Schubart *et al.* (1965), Sick (1951, 1953, 1993, 1997), da Silva (1995), Slud (1979), Snyder (1966), Stiles & Skutch (1989), Teixeira (1992), Terborgh *et al.* (1990), Tostain *et al.* (1992), Vanderwerf (1988), Wetmore (1968a), Young & Zook (1999).

2. Long-tailed Potoo

Nyctibius aethereus

French: Ibijau à longue queue **German:** Langschwanz-Tagschläfer **Spanish:** Nictibio Colilargo
Other common names: Large-tailed Potoo (*aethereus*, if two species recognized)

Taxonomy. *Caprimulgus aethereus* Wied, 1820, Rio Mucuri, Bahia, Brazil. Race *longicaudatus* (incorporating *chocoensis*) generally considered a distinct species for most of its recorded history, but recently lumped on rather scanty evidence; based on distinctive morphology, separate species status may be appropriate, although voices apparently similar. Relationships of all races require further study. Three subspecies currently recognized.

Subspecies and Distribution.

N. a. chocoensis Chapman, 1921 - Chocó region (W Colombia). *N. a. longicaudatus* (Spix, 1825) - scattered localities across Amazonia, probably throughout. *N. a. aethereus* (Wied, 1820) - Atlantic forest of SE Paraguay, NE Argentina and SE Brazil. A specimen from near mouth of R Amazon has been attributed to nominate *aethereus*, but probably erroneously.

Descriptive notes. 46-58 cm; 280-447 g. Long, strongly graduated tail, proportionately longer than in other species; species more rufescent overall than most congeners; conspicuous pale shoulder patch often present. Nominative race longer overall than bulkier *N. grandis*. Sexes alike. Race *chocoensis* darker, more richly coloured than similar *longicaudatus*; both considerably smaller and more rufescent than nominate, and proportionately longer-tailed. **VOICE.** Song a lethargic, plaintive, "ra-OOH" (with second syllable higher), repeated once every 5-10 seconds. Also, a series of short "woof" notes, like large owl. Voices of Atlantic and Amazonian races apparently very similar; voice of Chocó population unknown.

Habitat. Forests in lowlands, from very wet to relatively dry and gallery forest. Inhabits primary forest interior, from understorey to subcanopy, and edges; occasionally in open areas adjacent to forest.

Food and Feeding. Forages nocturnally like other potoos, consuming flying termites, moths and beetles. Appears clumsy and over-sized, making short, acrobatic sallies in the cluttered forest interior on its great wings and tail.

Breeding. Nesting reported Aug-Nov in Paraguay. Single spotted egg atop broken stub or fencepost. **Movements.** Presumed to be sedentary.

Status and Conservation. Not globally threatened. Very poorly known. Nominative subspecies probably threatened in Atlantic forest, where little original forest remains. Northern forms appear more likely to be overlooked rather than really rare; not threatened as long as extensive primary forest lasts; race *chocoensis*, however, has restricted distribution and is poorly known, so should perhaps be considered vulnerable.

Bibliography. dos Anjos *et al.* (1997), Bates *et al.* (1992), Bierregaard (1988), Brooks *et al.* (1993), Butler (1979), Canevari *et al.* (1991), Chapman (1921, 1926), Chebez (1994), Cohn-Haft *et al.* (1997), Collar & Andrew (1988), Greenway (1978), Hartert (1892), Hayes (1995), Hellmayr (1912), Hilty & Brown (1986), Laubmann (1940), Madroño & Esquivel (1997), Meyer de Schauensee (1966), Meyer de Schauensee & Phelps (1978), Ortiz & Carrión (1991), Parker, Donahue & Schulenberg (1994), Parker, Foster *et al.* (1993), Parker, Kratter & Wust (1994), Penard & Penard (1910), Pinto (1938), Salaman & Gandy (1994), Schubart *et al.* (1965), Sclater (1866a), Sick (1951, 1993, 1997), da Silva (1995), Snyder (1966), Stotz & Bierregaard (1989), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Straneck & Johnson (1990), Straube & Bornschein (1991, 1995), Wied (1820, 1830), Zimmer & Hilty (1997).

3. Northern Potoo

Nyctibius jamaicensis

French: Ibijau jamaïcain **German:** Mexikotagschläfer **Spanish:** Nictibio Jamaicano
Other common names: Common(!)/Jamaican/Antillean Potoo

Taxonomy. *Caprimulgus jamaicensis* J. F. Gmelin, 1789, Jamaica. Sometimes considered conspecific with *N. griseus*, with which it forms a superspecies; separation based on distinctly different voices. In Costa Rica, where both occur, there appear to be no consistent morphological characters to distinguish the two vocal types. The type specimen of race *costaricensis* comes from a region in Costa Rica where it is presumed only *jamaicensis* vocal type occurs, hence its placement within present species; most specimens previously attributed to *costaricensis*, however, including those from Caribbean slope of Nicaragua, probably represent the *N. griseus* vocal type. Mainland races *lambei* and *costaricensis* doubtfully valid, probably representing extremes in clinal variation, suggesting synonymy with *mexicanus*. Race *abbotti* once proposed to be separate species, based on longer song noted in sample of unspecified number of individuals. Thorough taxonomic revision needed. Five subspecies currently recognized.

Subspecies and Distribution.

N. j. lambei Davis, 1959 - Pacific slope of W Mexico. *N. j. mexicanus* Nelson, 1900 - E & S Mexico to El Salvador and Honduras, including Roatán I. *N. j. costaricensis* Ridgway, 1912 - Pacific slope of N & C Costa Rica, and possibly W Nicaragua. *N. j. jamaicensis* (J. F. Gmelin, 1789) - Jamaica. *N. j. abbotti* Richmond, 1917 - Hispaniola and Gonâve I.

Descriptive notes. 38-44 cm; 210-251 g. Within single populations, individuals vary from reddish brown to grey-brown; iris yellow. Sexes alike. Juvenile paler than adult. Mainland races weakly distinguished, based on subtle differences in size and overall darkness of plumage, possibly related to ecological factors such as humidity and latitude: dry-region forms paler, northerly forms larger. Races *jamaicensis* and *abbotti* similar to one another, with more conspicuous streaking on underparts than in mainland forms. **VOICE.** Song, in quality like that of *N. grandis*, but in pattern like that of *N. griseus*; a harsh, guttural, unmusical "bwaahawh."

"bwa-bwa-bwa"; up to ten final syllables in *abbotti*.

Habitat. Forest edge and open areas near forest or with scattered trees, including parks and farmland, even golf courses (Jamaica); humid and dry woodlands; lowlands occasionally up to 1500 m. Roosts during day in trees or atop poles. At night forages in open from fenceposts and snags.

Food and Feeding. Feeds on flying insects of all sizes, including Coleoptera, Homoptera, Hemiptera, Orthoptera, Lepidoptera and Neuroptera; one bird recorded eating a White-collared Seedeater (*Sporophila torqueola*). A nestling's stomach contained beetle larvae and bits of wood as well as more typical winged prey, all presumably fed to it by the parents. Forages nocturnally like all potoos, sallying from exposed perches after flying insects.

Breeding. Adults with enlarged gonads in Feb-Apr in Mexico and Belize; one May egg in Mexico; unfledged young in May in Mexico and Guatemala; nesting reported nearly throughout year in Jamaica, and Apr-Jul in Hispaniola. Nest is simple depression atop stub, where adult sits cryptically perched; site sometimes reoccupied in subsequent years. Lays 1 egg, white with grey, brown

and purplish blotches at wide end; male attends nest during the day, female at night, both parents feeding chick.

Movements. Presumed mainly sedentary; individual vagrants twice found on islands off Puerto Rico. **Status and Conservation.** Not globally threatened. Fairly common to rare and possibly local, but poorly known. In danger of extirpation in El Salvador; presumed presence in Nicaragua unconfirmed. Apparently tolerant of human-altered habitats, where some forest remains. Major threat is continued forest destruction throughout range. Health of populations in fragmented landscapes, such as those prevailing in most of range, not known; research and census work required.

Bibliography. Álvarez del Toro (1971), Anon. (1995a), Binford (1989), Bond (1985), Brodtkorb (1943), Cory (1886, 1918), Davis (1972, 1978), Dod (1987, 1992), Foster & Johnson (1974), Hardy & Webber (1975), Hartert (1892), Howell & Webb (1995a), Klaas (1968), Komar (1998), Land (1970), Lowery & Dalquest (1951), Monroe (1968), Paynter (1955), Raffaele (1981), Raffaele *et al.* (1998), Rand & Traylor (1954), Ridgway (1914), Rowley (1984), Russell (1964), Schaldach (1963), Sclater (1866a), Slud (1964), Smithe (1966), Stiles & Skutch (1989), Sutton (1950, 1951b), Thurber *et al.* (1987), Van Tyne (1935), Wetmore & Swales (1931).

4. Common Potoo

Nyctibius griseus

French: Ibijau gris **German:** Urutau-Tagschläfer **Spanish:** Nictibio Urutáu
Other common names: Grey/Lesser Potoo

Taxonomy. *Caprimulgus griseus* J. F. Gmelin, 1789, Cayenne. Forms superspecies with *N. jamaicensis*, and these two sometimes treated as conspecific, although voices differ greatly. Costa Rican birds, originally all included in single race, *costaricensis*, now thought to include two species; because *costaricensis* is currently recognized as a race of *N. jamaicensis*, birds of present species in Costa Rica and elsewhere in N are referred to adjacent race *panamensis*, although they possibly represent an unnamed taxon. Invalid race *cornutus*, recognized by some earlier authors, is now considered synonymous with nominate race, despite proposal for full species status based on geographically limited sample showing subtle differences in voice. Two subspecies currently accepted.

Subspecies and Distribution. *N. g. panamensis* Ridgway, 1912 - Nicaragua and SW Costa Rica to N South America W of Andes, from NW Venezuela to W Ecuador. *N. g. griseus* (J. F. Gmelin, 1789) - Trinidad and Tobago; E of Andes from Colombia, Venezuela and the Guianas to N Argentina, N Uruguay and S Brazil.

Descriptive notes. 33-38 cm; 145-202 g. Nearly identical to *N. jamaicensis*, especially in area of contact, although averages smaller throughout range. Colour variation within populations ranges from reddish-brown to grey-brown. Sexes alike. Juvenile whitish. Races weakly defined, based on subtle, perhaps clinal, differences in size and overall coloration. Voice. Song a haunting, drawn out, descending series: "feeoo, foo, foo, foo, ..." of roughly 4-8 pure or slightly raspy notes; first "note" sometimes distinctly two-toned, dropping abruptly in pitch. Sings most at dusk, just before dawn, and on moonlit nights.

Habitat. Open woodland, especially near water; savannas and plantations with trees, *cerrado*, *várzea* and *terra firme* forest edges, second growth and mangroves. Roosts in trees in canopy and at edges; forages in open places from exposed snags and atop posts and stumps, often within few metres of ground, where vegetation is low. Mainly in lowlands, but occasionally up to c. 2000 m. **Food and Feeding.** Feeds on beetles (including large fireflies), moths, true bugs, mantids, flying ants and termites, cicadas, leafhoppers and grasshoppers. Forages mostly solitarily, at night, especially during the crepuscular period. Searches for prey from exposed perches, turning head rapidly from side to side, in owl-like way. Sallies like a flycatcher after night-flying prey, often returning to same perch.

Breeding. Throughout range as a whole nesting has been noted during every month of the year, with no general seasonal or annual pattern; however, in any given region, it tends to occur at roughly the same time each year. Nest is shallow knot-hole or depression at broken stub, situated at medium-height in tree; no nesting material. Lays 1 egg, with violet and brown speckles, densest at broad end; incubation 1 month or longer; chick is brooded for as much as 3 weeks; fledging 40-50+ days. Male incubates and broods during the day, rarely moving and relying on cryptic coloration and posture to avoid detection; female incubates at night after brief foraging period at nightfall; parents take turns brooding and feeding chick through the night.

Movements. Apparently sedentary, although perhaps not maintaining permanent territories. Reported to be of sporadic occurrence at certain sites in Costa Rica. Apparent absence outside breeding season in S of range may reflect merely seasonal singing, rather than migratory movements. One reported case of ship-assisted vagrancy between Panama and Florida, thought to refer to present species.

Status and Conservation. Not globally threatened. Fairly common to uncommon; biology and status not well known, despite being the most intensively studied potoo species. Less strictly tied to primary forest than most other species and so more tolerant of human disturbance; nevertheless, the chief threat is habitat destruction.

Bibliography. Anon. 5. Andean Potoo

Nyctibius maculosus

French: Ibijau des Andes **German:** Andentagschläfer **Spanish:** Nictibio Andino

Taxonomy. *Nyctibius maculosus* Ridgway, 1912, Ambato, Ecuador.

For some time was considered a race of *N. leucopterus*, which differs, however, in size, plumage, voice, and elevational distribution. Monotypic.

Distribution. Scattered localities in Andes from W Venezuela and E Colombia through E Ecuador and E Peru to NW Bolivia.

Descriptive notes. 34-38 cm; 145-195 g. Similar size to that of *N. griseus*; dark brown overall, never grey as in some individuals of *N. griseus*. Variable amount of white in wing patch, never as extensive as in smaller *N. leucopterus*. Iris yellow. Sexes alike. Voice. Song, given on moonlit nights from one of several preferred perches, repeated at roughly 10-second intervals: a raspy "ra-AH", higher on second syllable; like a fast, high-pitched song of *N. aethereus*. Short, descending, three-note call apparently given by female in courtship.

Habitat. Montane subtropical and temperate cloudforest with openings, at elevations of 1800-2800 m. Perches on snags in canopy.

Food and Feeding. Stomachs contained large insects, including beetles.

Breeding. One copulation observed in Sept in Ecuador. Otherwise unknown; presumed to be broadly similar to other potoos.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Very poorly known; may be fairly common locally. Extensive research and survey work needed in order to establish ecological requirements, as well as population densities and trends.

Bibliography. Chapman (1926), Fitzpatrick & Willard (1982), Fjeldså & Krabbe (1990), Greenway (1978), Hilty & Brown (1986), Kirwan & Sharpe (1999), Krabbe (1992), Meyer de Schauensee & Phelps (1978), Ortiz & Carrión (1991), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Remsen & Traylor (1983, 1989), Ridgway (1912a, 1914), Schulenberg & Aubrey (1997), Schulenberg *et al.* (1984).

6. White-winged Potoo

Nyctibius leucopterus

French: Ibijau à ailes blanches **German:** Weißflügel-Tagschläfer **Spanish:** Nictibio Aliblanco

Taxonomy. *Caprimulgus leucopterus* Wied, 1821, near Conquista, Bahia, Brazil. Formerly considered to include *N. maculosus*, which differs, however, in size, plumage, voice, and elevational distribution. Includes two populations: Amazonian form is a new taxon, as yet undescribed, perhaps deserving species status. Currently treated as monotypic.

Distribution. Lowlands of Amazonia in N Brazil, S Guyana and distantly scattered unpublished localities, probably occurring throughout; also single site in E Brazil (type locality).

Descriptive notes. 24-29 cm; 77-85 g in Amazonia, weight of eastern form unknown. Relatively short-tailed; dark brown, paler below; conspicuous, large white patch across secondary coverts. Sexes apparently alike. Variability in extent of white wing patch and of reddish tones in brown may be age- or sex-related. Amazonian form much smaller than eastern, the two virtually identical in coloration. Voice. Haunting, melancholy, whistled song in Amazonia, given mostly on moonlit nights: a gradually descending, pure-toned "feeoooooooo" lasting c. 4 seconds; sometimes rising slightly at beginning. Call a soft, single or repeated "bweep".

Habitat. In Amazonia, canopy of primary lowland *terra firme* rainforest, including lighter forest on sandy soil. In E Brazil, habitat unknown; species presumed to occur similarly in canopy of primary Atlantic rainforest.

Food and Feeding. Small to medium-sized flying insects, including beetles, moths, cicadas, mantids, orthopterans, winged termites, and true bugs. Forages by sallying into air from exposed perches at night.

Breeding. Unknown. Habits presumed to be similar to those of congeners; nest probably situated in canopy.

Movements. Probably sedentary.

Status and Conservation. Not globally threatened. E Brazilian form is unknown in life, and probably limited to remnant patches of Atlantic rainforest, where it is highly threatened or possibly even extinct. Amazonian form, only recently discovered, has been found as being common to uncommon at scattered distant localities; probably occurs throughout Amazonia in appropriate habitat, where the biggest threat comes from continued destruction of pristine forest.

Bibliography. Chapman (1926), Cohn-Haft (1993, 1998), Cohn-Haft *et al.* (1997), Collar & Andrew (1988), Greenway (1978), Hartert (1892), Parker *et al.* (1993), Peres & Whittaker (1991), Schulenberg *et al.* (1984), Sick (1993, 1997), Wied (1821, 1830), Willis (1992).

7. Rufous Potoo

Nyctibius bracteatus

French: Ibijau roux **German:** Tropfentagschläfer **Spanish:** Nictibio Rufo

Taxonomy. *Nyctibius bracteatus* Gould, 1846, Bogotá, Colombia. Monotypic.

Distribution. Known from scattered localities in E Ecuador and E Peru to N Brazil and Guyana; probably occurs throughout lowland Amazonia.

Descriptive notes. 21-25 cm; 46-58 g. Smallest and atypically coloured potoo; overall deep orange-rufous coloration, with large white spots narrowly bordered in black, resembling Oilbird (*Steatornis caripensis*) and red morph of some *Aegotheles* species; long bristles ema-

nating from loral region; yellow iris has dark wedge in the lowest portion. Sexes alike. Juvenile plumage browner without white spots, more typical of adults of other potoo species. **VOICE.** Song a soft, rapidly descending series of roughly 10-15 notes: "bu-bu-bu-bu-bu-bu...", reminiscent of an *Otus* screech-owl or Amazonian Pygmy-Owl (*Glaucidium hardyi*). Call a single note, "wup", raspier than that of *N. leucopterus*. Another vocalization, "quaaw-co", for some time attributed to present species but almost certainly erroneously. **Habitat.** Occupies understorey and middle storey of primary lowland *terra firme* rainforest and also swampy palm forests. Can occasionally be found perching within 1 m of ground, but usually higher up. **Food and Feeding.** Consumes flying insects of orders Coleoptera, Orthoptera, Lepidoptera, Hymenoptera and Neuroptera. Forages like other potoos, with short upward- or outward-directed sallies, typically returning to same perch.

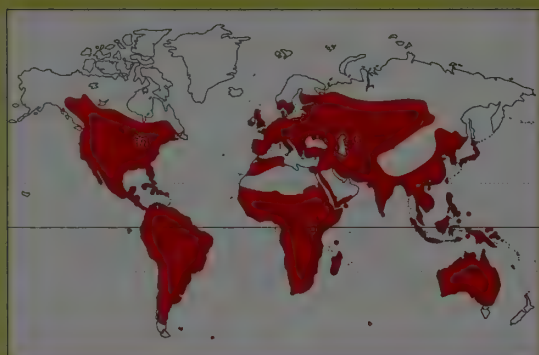

Breeding. Single nest known, from Brazil, occupied Sept to Dec: 1 blotched egg atop broken stub, inside rainforest; both adults participated in nesting tasks; fledgling, not yet adult size, still fed by parents away from nest. **Movements.** Presumed sedentary. **Status and Conservation.** Not globally threatened. Very poorly known; perhaps locally distributed, and probably not common. Probably not seriously threatened as long as extensive areas of Amazonian forest remain intact; needs further study to determine specific habitat preferences and distributional limits. **Bibliography.** Bierregaard (1988), Butler (1979), Cohn-Haft (1989, 1998), Cohn-Haft *et al.* (1997), Collar & Andrew (1988), Hartert (1892), Hilty & Brown (1986), Parker, Donahue & Schulenberg (1994), Parker, Parker & Plenge (1982), Penard & Penard (1910), Selater (1866a, 1866b), Sick (1993, 1997), Snyder (1966), Stotz & Bierregaard (1989), Stotz *et al.* (1996).

Class AVES

Order CAPRIMULGIFORMES

Suborder CAPRIMULGI

Family CAPRIMULGIDAE (NIGHTJARS)

- Small to large nocturnal birds, with variegated plumage, large mouth, long wings and tail, and short legs.
- 15-40 cm (with tail streamers, up to c. 100 cm).

- Cosmopolitan, although absent from polar regions.
- Desert, grassland and open wooded country to forest, from sea-level up to 4200 m.
- 15 genera, 89 species, 221 taxa.
- 6 species threatened; none definitely extinct since 1600.

Systematics

The rather primitive-looking nightjars have probably arisen from ancient landbirds, but, despite the valuable fossil evidence now available, their true origins still remain unknown. Their earliest ancestors so far identified belong to an extinct family of ancient caprimulgid birds, the Archaeotrogonidae, that date back to the late Eocene some 40 million years ago. Originally considered to be fossil trogons that lacked the heterodactyl foot typical of modern trogons (Trogonidae), four species have so far been discovered in the Phosphorites du Quercy deposits in south-west France and have been placed in an extinct genus *Archaeotrogon*. One species, *Archaeotrogon venustus*, appears to have been more successful than the others, its fossil remains showing that it had a temporal span of approximately 14 million years. Two of the others do not appear earlier than about 32-30 million years ago during the Oligocene, and data for the fourth are insufficient for accurate dating. Fossil Caprimulgidae also date back to similar times, a species from the Upper Eocene of the Phosphorites du Quercy being placed in an extinct genus *Ventivorus*, and an as yet unidentified species taken from the Middle Eocene Messil oil shales clearly showing a characteristic nightjar-like foot. Fossil material from the much less distant Quaternary period is also well documented: apart from the Cuban species *Siphonorhis daiquiri*, apparently long extinct, and the Jamaican Poorwill (*Siphonorhis americana*), which might also be extinct, evidence is available for extant species from Europe, North and South America, Puerto Rico and Australia.

Since the 1750's, taxonomists have classified the various caprimulgiforms in many different ways, especially when attempting to determine their relationships with other birds. Frequently treated as relatives of the owls (Strigiformes) and the swifts (Apodidae), they have also been linked with hummingbirds (Trochilidae), trogons, todies (Todiidae), motmots (Momotidae), bee-eaters (Meropidae), rollers (Coraciidae), jacamars (Galbulidae) and puffbirds (Bucconidae), while another grouping often placed nightjars close to the swallows (Hirundinidae) within the passerines, with swallows formerly being considered relatives of the swifts. Superficial ties between nightjars and swifts are suggested by their adaptations to feeding, species in both families being aerial insectivores with wide gapes, while owls and nightjars share soft, variegated plumages and nocturnal habits, although several authorities put all of these similarities down to convergence. The scientific evidence, however, shows that

there are some morphological similarities which appear to confirm a phylogeny linking the owls, nightjars and other Caprimulgiformes (see below), and this is further supported by results from recent DNA-DNA hybridization studies.

During the second half of the eighteenth century, all caprimulgiform birds were assigned to the single genus *Caprimulgus*; it was not until the early nineteenth century that ornithologists realized that some of the species were so different that they actually belonged not only in separate genera, but also in separate families. Thus, by the 1830's, the Oilbird (*Steatornis caripensis*), the frogmouths (Podargidae), the owl-nightjars (Aegothelidae) and the potoos (Nyctibiidae) had been separated from the nightjars, although it was often recognized that, aside from their relationships to other birds, they were each other's closest relatives. From this time also, taxonomists began to separate the true nightjars into different genera, and it seems that the

Subdivision of the
Caprimulgidae

[Figure: Dave Nurney &
Angels Jutglar]

The nightjars comprise a fairly diverse assemblage of nocturnal aerial insectivores.

Of 51 different genera that have at various times been recognized within the family Caprimulgidae, only 15 are currently considered valid.

The Ocellated Poorwill belongs to the group loosely known as the poorwills. They are restricted to North and South America and are amongst the smallest of the nightjars, having shorter and more rounded wings than other species and extremely long rectal bristles.

[*Nyctiphrynus ocellatus*

Oxford Scientific Films]

only thing they could actually agree upon was that all members of the family were instantly recognizable as being nightjars. These changes in genera covered species in all parts of the world, although the greatest re-evaluation concerned the Americas, many authors arguing that all New World species differed from their Old World *Caprimulgus* counterparts. In all, 51 different nightjar genera have been named since 1758, although the number of genera considered valid currently stands at 15.

The so-called nighthawks are thought to have originated in South America and now breed throughout much of North America and the Neotropics. Nighthawks differ from nightjars in having a desmognathous palate, that of the nightjars being schizognathous; they differ further in generally lacking elongated rectal bristles around the gape, and in often being more active during the day. They are placed in a separate subfamily, the Chordeilinae, all other nightjars being placed in the subfamily Caprimulginae. Four genera of nighthawks are currently recognized: *Chordeiles*, containing six species, is the largest and most widespread; *Lurocalis* comprises two species; and both *Nyctiprogne* and *Podager* are monotypic.

The genus *Eurostopodus* comprises seven species that also lack prominent rectal bristles. Found in Australia, New Guinea, Sulawesi and many parts of Asia, these are fairly large birds that do not have white markings on the tail, while the majority of species also lack prominent white spots on the outer primaries. Two species also have elongated feathers on each side of the head, at the rear of the crown, from which the term "eared-nightjars" has been coined.

The New World poorwills are among the smallest of the nightjars, comprising seven species divided into three genera. They have brownish wings that are strongly banded tawny or buffish and lack white markings, and have most of their tail feathers tipped with white. *Nyctiphrynus* numbers four Central and South American species, including two endemic to Mexico and one endemic to the Chocó faunal region of Colombia. *Siphonorhis* contains two species, one endemic to Hispaniola, the other to Jamaica, although the latter may be extinct, not having been seen with certainty since the middle of the nineteenth century. The other genus within this group is the monotypic *Phalaenoptilus* of North America and northern Mexico. Loosely clumped alongside this group is the distinctive genus *Nyctidromus*.

The most widespread and species-rich genus is *Caprimulgus*, containing 56 species of "typical" nightjars that often have variegated plumages, white wing and/or tail markings (at least in males) and long rectal bristles around the gape. On the basis of main breeding ranges, Africa has the highest number, with 19 species, while Asia and South America have 12 each. Central America and the Caribbean islands are home to seven, Madagascar has two endemics, and North America and Europe have two apiece.

The Afrotropical genus *Macrodipteryx* contains two species, in which the males grow elaborate and elongated second (innermost) primaries prior to the breeding season. Finally, four distinctive genera are to be found in South America. These are *Hydropsalis* and *Uropsalis*, each containing two species, and *Macropsalis* with one species, all of which may possibly be closely related, and the monotypic *Eleothreptus*. The *Hydropsalis* nightjars are characterized by the unique tail shape of the breeding males, while *Uropsalis* and *Macropsalis* males have extremely elongated outermost tail feathers, the two groups possibly being linked by the male Scissor-tailed Nightjar (*Hydropsalis torquata*), which also has elongated outer tail feathers.

For many years, all *Lurocalis* nighthawks were thought to belong to one species, the Short-tailed or Semi-collared Nighthawk (*Lurocalis semitorquatus*), although the larger Andean form has different vocalizations and morphological characteristics and is now recognized as a distinct species, the Rufous-bellied Nighthawk (*Lurocalis rufiventris*). The Semi-collared's southern migratory form *nattereri*, sometimes known as the Chestnut-bellied Nighthawk, is also regarded as specifically separable by some ornithologists, although its similar vocalizations would suggest that further studies are needed if this split is to be convincingly justified.

The *Chordeiles* nighthawks are a distinct group of partially diurnal nightjars, occurring throughout much of North, Central and South America. Three species, the Common Nighthawk (*Chordeiles minor*), the Lesser Nighthawk (*Chordeiles acutipennis*) and the Least Nighthawk (*Chordeiles pusillus*), have vast breeding ranges and are subdivided into numerous subspecies. The Antillean Nighthawk (*Chordeiles gundlachii*) was long regarded as a Caribbean form of the Common Nighthawk, but its different vocalizations and its sympatric breeding on the Florida Keys confirm its status as

■ distinct species. The recently described Bahian Nighthawk (*Chordeiles vielliardi*), assigned to the genus *Chordeiles* on the basis of two museum specimens and brief vocal and behavioural evidence, has generated a certain amount of interest and comment, and recent field observations suggest that it might actually be more closely related to the Band-tailed Nighthawk (*Nyctiprogne leucopyga*). The Sand-coloured Nighthawk (*Chordeiles rupestris*) is the remaining member of this group and is highly adapted to life along the sandbars and riverbanks of large South American waterways. The Nacunda Nighthawk (*Podager nacunda*) is a distinctively large, boldly marked Neotropical species which remains within a genus of its own.

Those nightjars within the genus *Eurostopodus* are medium-sized to large birds that range from India east to China, and south through Sumatra, Borneo, Sulawesi and New Guinea to Australia, the Solomon Islands and New Caledonia. Evidence from recent DNA-DNA hybridization studies suggests that they may be sufficiently different from the rest of the Caprimulgidae to warrant placing them in a separate "sister" family, the Eurostopodidae, and the term "eared-nightjars" is increasingly being used when referring to species within this group. However, only two species, the Great Eared-nightjar (*Eurostopodus macrotis*) and the Malaysian Eared-nightjar (*Eurostopodus temminckii*), appear to have the "ear-tufts" at the back of the head, and they also differ from other *Eurostopodus* nightjars in their whistled call-notes, which are often given in flight, and in having ranges that extend into mainland Asia. Further studies may suggest that these two species be separated from the five "non-eared" nightjars; if so, the genus *Lyncornis* is available for them. The genus *Eurostopodus* was first used for the two species that occur in Australia, these being the Spotted Nightjar (*Eurostopodus argus*) and the White-throated Nightjar (*Eurostopodus mystacalis*). It is interesting to note that these two also show some morphological, vocal and ecological differences from their congeners, which begs the question whether the three remaining species, the Papuan Nightjar (*Eurostopodus papuensis*) and Archbold's Nightjar (*Eurostopodus archboldi*), both endemic to New Guinea, and Heinrich's Nightjar (*Eurostopodus diabolicus*), endemic to Sulawesi, are separable as a third genus. Two other island forms also require further study: birds on the Solomon Islands and New Caledonia are currently regarded as subspecies of the White-

throated Nightjar of Australia but may yet prove to be one, or even two, separate species.

Eight species classified in four genera occur only in the Americas. The Common Poorwill (*Phalaenoptilus nuttallii*) presents no real taxonomic problems. Nor does the Pauraque (*Nyctidromus albicollis*), although it was originally described as a *Caprimulgus* nightjar and was also tentatively linked with the *Siphonorhis* poorwills by some early ornithologists. Two species are placed in the latter genus: the possibly extinct Jamaican Poorwill and the Least Poorwill (*Siphonorhis brewsteri*) of Hispaniola. These are distinctive but poorly known species, with long tarsi, a wide bill and prominent, tubular nostrils. Although obviously closely related to the Jamaican Poorwill, the Least Poorwill was originally named in a separate genus, *Microsiphonorhis*. The four *Nyctiphrynus* poorwills are small, Neotropical nightjars about which very little seems to be known. Two species, the Eared Poorwill (*Nyctiphrynus mcleodii*) and the Yucatan Poorwill (*Nyctiphrynus yucatanicus*), are Central American endemics occurring mainly in Mexico, while a third species, the Ocellated Poorwill (*Nyctiphrynus ocellatus*), is found mainly in South America, although a small, rather disjunct population occurs in Central America. These three poorwills share several morphological features such as extremely long rictal bristles, dense crown feathers, and all but the central pair of tail feathers tipped white. The fourth species, the Choco Poorwill (*Nyctiphrynus rosenbergi*), is possibly worthy of further generic study as it differs from the other three in all of those respects.

The genus *Caprimulgus* encompasses most nightjar species and has representatives breeding in all of the world's faunal zones. Within the genus, there are many species that are obviously closely related to others, and at least ten groups of superspecies are possibly recognizable. Many other members of the genus show no immediate affinities with other nightjars, including probably a few that should not be classified as *Caprimulgus* nightjars at all.

Among the 21 New World species of *Caprimulgus*, there are possibly four or five groups of closely related nightjars covering 9-12 species. The first comprises the Chuck-will's-widow (*Caprimulgus carolinensis*) and the Rufous Nightjar (*Caprimulgus rufus*), which share similar plumages and vocalizations, while a second grouping covers two Caribbean endemics, the Cuban Nightjar (*Caprimulgus cubanensis*) and the Hispaniolan

Containing 56 species and spanning six continents, *Caprimulgus* is currently the largest and most widely distributed of the nightjar genera. It can be grouped into ten superspecies although ■ few taxa with no obvious affinities might best be allocated to separate genera. The Spot-tailed Nightjar perhaps belongs in this second category. It inhabits the grasslands, marshlands and scrub of South and Central America. While its long wings, tiny legs and variegated patterning are typical of the group, the unusual high-pitched call and tail-spotting of males suggest that it is not closely related to any other *Caprimulgus* species.

[*Caprimulgus maculicaudus*, Montsinéry, French Guiana. Photo: Jany Sauvanet/ NHPA]

For centuries, nightjars have been immersed in superstition and folklore as a result of their strange calls and mysterious nocturnal habits, and their shyness makes them extremely difficult to study. For instance, examination of current literature reveals almost nothing about the foraging behaviour or breeding biology of the Hispaniolan Nightjar. Several other species are known only from a few old specimens or rumours. Gradually, however, ornithologists are rediscovering missing taxa, using radio-telemetry to elucidate behaviour and recording the vocalizations of obscure species, thus facilitating their detection.

Nightjar (*Caprimulgus ekmani*), which until recently were generally considered to be conspecific. A third group links the Silky-tailed Nightjar (*Caprimulgus sericocaudatus*) of South America with two Central American endemics, the Tawny-collared Nightjar (*Caprimulgus salvini*) and the Yucatan Nightjar (*Caprimulgus badius*), all three again being considered conspecific at times. Two small, dark nightjars, the Blackish Nightjar (*Caprimulgus nigrescens*) and the little-known Roraiman Nightjar (*Caprimulgus whitelyi*), perhaps represent a further grouping; while yet another is possibly formed by the Whip-poor-will (*Caprimulgus vociferus*), the Puerto Rican Nightjar (*Caprimulgus noctitherus*) and the Dusky Nightjar (*Caprimulgus saturatus*).

Outside these close groupings, the Scrub Nightjar (*Caprimulgus anthonyi*) is endemic to the lowlands of western Colombia and Ecuador and until recently was considered to be conspecific with the widespread and fairly abundant Little Nightjar (*Caprimulgus parvulus*), the two not finally being recognized as separate species until the 1960's. The Cayenne Nightjar (*Caprimulgus maculosus*) is the rarest South American representative of the family, still known only from the type specimen, a male, taken in French Guiana in 1917. It is a small, brownish but nevertheless distinctive forest nightjar which, as some taxonomists have suggested, might be related to the Blackish and Roraiman Nightjar grouping.

Even less clearly related to other New World *Caprimulgus* species, the scarce and localized White-winged Nightjar (*Caprimulgus candicans*) perhaps does not belong in this genus. Described in the mid-1860's from two specimens, an adult male and a probable immature female, it remained something of a mystery until the 1990's, when birds began to be discovered at sites in Brazil, Bolivia and Paraguay. It has occasionally been linked with the White-tailed Nightjar (*Caprimulgus cayennensis*), possibly due to the amount of white in the tail of the adult male. However, examination of the type specimens, together with recent field observations, show that it exhibits several similarities to the Sickie-winged Nightjar (*Eleothreptus anomalus*), including the same sexual dimorphism, with males sharing some morphological features such as a generally cinnamon-based plumage and blackish, curved outer primaries, and females sharing a browner plumage and straighter, browner wings that are regularly barred tawny. Both species also appear to prefer grassland

habitats and have similar vocalizations and breeding habits, all of which supports the view that the White-winged Nightjar may actually be better placed in *Eleothreptus*. The remaining species found in the Americas are the Buff-collared (*Caprimulgus ridgwayi*), Band-winged (*Caprimulgus longirostris*), Spot-tailed (*Caprimulgus maculicaudus*) and Pygmy Nightjars (*Caprimulgus hirundinaceus*).

Among Afrotropical *Caprimulgus* nightjars, there are perhaps four groups of closely related species containing four, three, three and two members respectively. The remaining species in this region show no real ties with other nightjars, although the rare and almost unknown Prigogine's Nightjar (*Caprimulgus prigoginei*) looks remarkably similar to the Javan form *bartelsi* of Salvadori's Nightjar (*Caprimulgus pulchellus*), especially in the extent and shape of its wing and tail markings. One superspecies group contains species that generally inhabit wooded country and have whistled songs, although ornithologists are still divided as to how many species are involved. A common view is that there may be four in total: two lowland species, the Black-shouldered (*Caprimulgus nigriscapularis*) and Fiery-necked Nightjars (*Caprimulgus pectoralis*); and two upland ones, the Abyssinian (*Caprimulgus poliocephalus*) and Montane Nightjars (*Caprimulgus ruwenzorii*). A second group contains three species with churring songs: the southern African Rufous-cheeked Nightjar (*Caprimulgus rufigena*); the eastern African Sombre Nightjar (*Caprimulgus fraenatus*); and the European Nightjar (*Caprimulgus europaeus*), which has a breeding toehold in the extreme north-west of the continent. Another group of nightjars with churring songs comprises the Long-tailed (*Caprimulgus climacurus*), Slender-tailed (*Caprimulgus clarus*) and Mozambique Nightjars (*Caprimulgus fossii*). In the past, these three species were placed in their own genus *Scotornis*, being separable from *Caprimulgus* on the grounds of having graduated tail feathers, although the Mozambique Nightjar proved to be intermediate between *Scotornis* and *Caprimulgus* in having a slightly squarer, less strongly graduated tail. The final group comprises two species which superficially look very alike, the Plain Nightjar (*Caprimulgus inornatus*) and the poorly known Star-spotted Nightjar (*Caprimulgus stellatus*), although vocal and morphological differences, as well as their sympatric breeding range in East Africa, possibly invalidate their pairing as a superspecies.

Most nightjars have variegated plumage, the overall coloration of which tends to be related to the local soil or the habitat type frequented. The birds are most vulnerable during daylight when they roost on the ground, and cryptic plumage has evolved to minimize the likelihood of detection by diurnal predators. While many nightjars have conspicuous white patches in the primaries and outer-tail feathers, these are concealed when the tail is closed and the wing folded. Although deserts and semi-deserts with very little vegetation would appear to be a dangerous and unsuitable habitat for nightjars, several species have adapted to these harsh environments. This is reflected in the pallid and densely speckled plumage of the Egyptian Nightjar, closely matching the appearance of Saharan sand. Other species occur in dense vegetation and require much darker and more coarsely patterned plumage. The Pauraque, for example, displays a pattern of gold, black and rich brown that helps it to blend in with the leaf litter of Neotropical forests.

Patricia Fogden]

The remaining African species are: Bates's Nightjar (*Caprimulgus batesi*); the Freckled Nightjar (*Caprimulgus tristigma*); the Swamp Nightjar (*Caprimulgus natalensis*); Donaldson-Smith's Nightjar (*Caprimulgus donaldsoni*); the Golden Nightjar (*Caprimulgus eximius*); the Nubian Nightjar (*Caprimulgus nubicus*); the Egyptian Nightjar (*Caprimulgus aegyptius*), which also has a separate breeding population in Asia; the Red-necked Nightjar (*Caprimulgus ruficollis*), which also breeds in the Iberian Peninsula; and the distinctive Brown Nightjar (*Caprimulgus binotatus*). The last of these was once placed in its own genus *Veles*, and probably deserves to be returned there owing to its morphological differences from other

Caprimulgus species. These features include small "ear-tufts" at the rear of the head, slightly curved outer primaries, and stiff tail feathers which are held in an inverted "V" posture when the bird is at rest.

The two Madagascan endemics within this genus are the Collared Nightjar (*Caprimulgus enarratus*), a boldly marked species which regularly nests in epiphytic or free-standing ferns above ground level and may be worthy of further taxonomic study, and the fairly common Madagascar Nightjar (*Caprimulgus madagascariensis*), which looks and sounds remarkably similar to a widespread Asian species, the Indian Nightjar (*Caprimulgus asiaticus*).

The Common Poorwill occupies a monotypic genus, one peculiarity being that it regularly enters torpor in response to low temperatures and low food abundance, sometimes for long periods in a kind of hibernation during the non-breeding season. While dormant, or during daytime, its plumage defends it from the danger of predation, being perfectly adapted to blend in with rock and gravel in the deserts, plains and prairies of North America.

The Ladder-tailed Nightjar's plumage is patterned differently to protect this species while it roosts and nests on the sandbars and beaches exposed during the dry season along South American rivers. Roosting nightjars tend to flatten themselves when danger approaches, behaviour that results in a reduction of shadow and outline; also, they often close their eyes almost completely to increase their crypsis, appearing restful while actually remaining acutely alert.

There are fewer *Caprimulgus* nightjars in Asia and only one superspecies grouping, the latter containing the Large-tailed (*Caprimulgus macrurus*), Jerdon's (*Caprimulgus atripennis*), the Philippine (*Caprimulgus manillensis*) and the Sulawesi Nightjars (*Caprimulgus celebensis*), all four having previously been regarded as conspecific. The ten subspecies of the widespread Savanna Nightjar (*Caprimulgus affinis*) are roughly split into seven southern, island forms and three larger northern forms, the latter having formerly been classified as a separate species called Franklin's Nightjar (*Caprimulgus monticolus*). There are three central Asian desert nightjars: Vaurie's Nightjar (*Caprimulgus centralasicus*), Sykes's Night-

jar (*Caprimulgus mahrattensis*) and the Asian population of the Egyptian Nightjar. Superficially, Sykes's and the Egyptian are very similar to look at, but because of their differing vocalizations and wing and tail markings they are not considered to be so closely related as to form a superspecies. Vaurie's Nightjar is certainly worthy of further study: it is still known only from the type specimen taken in 1929, although it remained misidentified as an Egyptian Nightjar for 31 years, eventually being described as a new species in 1960. Apart from the Indian and Salvadori's Nightjars, mentioned above, the two remaining Asian species are the Jungle Nightjar (*Caprimulgus indicus*), which is occasionally described as the

eastern counterpart of the European Nightjar, and the little-known Bonaparte's Nightjar (*Caprimulgus concretus*) of Sumatra, Borneo and Belitung Island.

The two highly distinctive *Macrodipteryx* species occur only in Africa. Although the Pennant-winged Nightjar (*Macrodipteryx vexillarius*) and the Standard-winged Nightjar (*Macrodipteryx longipennis*) are currently placed in the same genus, they are not thought to be sufficiently closely related to represent a superspecies, and indeed for many years taxonomists placed the Pennant-winged in its own genus, *Semeiophorus*.

The five remaining nightjars are all poorly known South American species. The Ladder-tailed (*Hydropsalis climacocerca*) and Scissor-tailed Nightjars appear to be related and share the same genus, while the Swallow-tailed (*Uropsalis segmentata*)

and Lyre-tailed Nightjars (*Uropsalis lyra*) share another. The rare Long-trained Nightjar (*Macropsalis forcipata*) is a monotypic species with its own genus.

One recent discovery has posed quite an interesting problem to taxonomists. During a 1990 survey of the Nechisar National Park in southern Ethiopia, remains of the decomposing corpse of a nightjar were encountered half-buried in a vehicle track in a treeless area. Tantalizingly for science, the tail feathers blew away while the remains were being freed from the soil, but a single wing was recovered in fair condition. Subsequent comparison of the wing with those of the four species known from the area showed it to be markedly larger. This called for the identification attempt to be transferred to the museum desks, where the wing was compared with skins of other large African nightjar species, and then of all other nightjar species available. After extensive examination, it emerged that this wing was amongst the most distinctive of any nightjar, in particular because of the positioning of the white primary patch unusually close to the carpal joint; it was not similar to that of any other species known. On this basis, the wing was used to describe the Nechisar Nightjar (*Caprimulgus solala*). Nevertheless, despite the extensive analysis and the undeniable distinctiveness of the wing, the validity of the species remains under question. A single wing seems rather a meagre sample to permit the definite conclusion that a distinct species is involved, especially as the differences, while notable within the context of nightjars, are not perhaps so very remarkable. Although the chances that this wing belonged to an aberrant individual are difficult to reconcile with the array of species that could potentially be involved, they can not be convincingly ruled out, so for the present the best course may be to delay its recognition as a valid species until more evidence is produced; this is the view adopted here. It is sometimes argued that recognizing a dubious form as a valid species can help promote interest in its conservation. However, in this case it may be that tentative rejection of this claimed species may actually act as a stronger spur for ornithologists to go out and try to prove beyond all doubt its existence as a valid species.

Morphological Aspects

Nightjars are generally medium-sized birds with fairly long wings, although they range in size from the Neotropical Least Nighthawk, which averages 15-19 cm in length and weighs less than 30 g, to the Great Eared-nightjar of Asia, which can measure up to 40 cm and weigh over 150 g. In addition, the males of

Although most nightjars rely on vocal communication to advertise for mates and defend territories, some species have evolved conspicuous visual signals which are used in display. The outer tail feathers of male Scissor-tailed Nightjars can reach 36 cm in length and thus protrude conspicuously beyond the remaining rectrices. This deeply forked tail is made obvious during courtship when stereotyped displays are performed on open patches of ground. Males extend their wings, then close them rapidly, making a small snapping sound and simultaneously hopping into the air.

[*Hydropsalis torquata fuscifera*, Cerro Corá National Park, Anambay, Paraguay. Photo: Robert Behrstock/VIREO]

The genus *Uropsalis* comprises two spectacular species largely restricted to the Andean cloudforests. One of these, the Lyre-tailed Nightjar, ranges from Venezuela to northern Argentina. During the breeding season males grow extremely long tail feathers which can reach some 75 cm in length. Several males often gather at communal leks, flicking these plumes to and fro when hovering, and calling in flight and pursuing females which visit the display ground.

[*Uropsalis lyra lyra*, La Soledad, Mérida, Venezuela. Photos: Robert Behrstock/VIREO]

Another species with sexually selected plumage modifications is the Pennant-winged Nightjar of sub-Saharan Africa, although in this case the elongated feathers are inner primaries rather than rectrices. These feathers are displayed by males at leks either in flight or on the ground. While individual males appear to hold territories within leks, they are not territorial at breeding sites and in many areas the species forms loose colonies with several nests only a few metres apart.

[*Macrodipteryx vexillarius*, near Bulawayo, Zimbabwe.
Photo: Brendan Ryan/Planet Earth]

several species can appear even larger in their breeding plumage. In the Neotropics, the males of a number of species have extremely long outermost tail feathers, which in the Lyre-tailed Nightjar can be up to about 75 cm long, while in the Afrotropics, the males of two species grow enormously elongated second primaries.

For their size, most nightjars appear to be reasonably large-headed, and yet, despite this, they have only a very small, weak-looking bill. They do, however, have an enormous gape, with an extremely sensitive palate, and are able to open their mouths both vertically and horizontally by using a highly specialized spreading mechanism of the lower jaw. In addition, their eyes are relatively large and situated laterally on the head. All these adaptations are, of course, advantageous to a nocturnal, aerial feeding strategy, but the skull consequently needs to be large enough to support these features. Nightjars have raised nostrils that are usually found along the top and towards the rear of the upper mandible, and in most species the gape is surrounded by extremely long, and possibly very tactile, rictal bristles, the exceptions being the nighthawks and the *Eurostopodus* nightjars. These bristles are actually strong, barbless contour feathers which are connected to special muscles in the skin, and are probably a further adaptation to nocturnal feeding. Evidence of another, possibly unique morphological feature in nightjars shows up only at night: this is the distinctive "eye-shine" that is noticeable when the birds are seen in artificial light. This is the result of light hitting a reflective surface called a tapetum, which is situated behind a layer of photoreceptors in the retina, at the back of the eye. A tapetum helps to increase the amount of light entering the eye and therefore improves vision at dusk and dawn and during moonlit nights, and is yet a further adaptation to nocturnal activities.

Nightjars are superb fliers and generally have long, slender wings with fairly pointed tips, although some species, such as the poorwills, have slightly shorter, broader and more rounded wings. A few species have evolved very unusual wing and tail structures which are used during courtship display flights (see Breeding). Male Pennant-winged and Standard-winged Nightjars of tropical Africa develop a greatly elongated pair of inner primaries, while male Sickie-winged Nightjars of South America have curved primaries and very short, almost non-existent-looking secondaries. Breeding males of five other South American species, the Ladder-tailed, Scissor-tailed, Long-trained, Swallow-tailed and Lyre-tailed Nightjars, possess unusually shaped and/or elongated outer tail feathers. Whatever their overall wing shape, all species are extremely agile in the air and obtain their high

degree of aerial skill through low wing-loading, which is achieved by having a very large wing area in proportion to body weight, and by having a highly manoeuvrable tail which serves as a perfect rudder.

Most nightjars have short tarsi and small, weak feet, which might suggest that they are uncomfortable on the ground. This is not, however, the case and many species can walk quite strongly, this being especially true of chicks. Some occasionally feed on the ground by picking up or even chasing insects. Species with rather longer tarsi include the Nacunda Nighthawk, the *Siphonorhis* poorwills and the Pauraque, which is quite at home on the ground and is often considered to be the most terrestrial of all nightjars. All members of the Caprimulgidae have partly webbed toes, with four phalanges in the outermost toe, two phalanges in the hallux, and a pectinate middle toe. The pecten is a small comb-like structure situated on the inner side of the claw and is possibly used for removing parasites, or straightening out the rictal bristles, during preening.

Adaptations to local environmental conditions take several forms. An important one for many nightjar species is the ability to withstand extremes of temperature. Nightjars are commonest in warmer climates and often roost and nest in open situations where they can be subjected to long periods of direct exposure to the sun. In these circumstances, they can keep cool by losing heat through gular fluttering, during which the mouth is opened, the gular area is vibrated, and the rate of blood flow to the buccal area is increased. Nightjars may also be able to maintain their brain temperature at a lower level than the rest of their body, by way of heat exchange through a highly vascularized region in the temples; this is certainly known to occur in one species, the Lesser Nighthawk.

Some nightjars also experience periods of cold weather, which affects not only their own level of activity but also that of their insect prey. At least some species have the physiological ability to lower their body temperature, reduce their rate of metabolism, and therefore become capable of entering and arousing from torpor. The first documented case of torpidity in nightjars is that of a Common Poorwill found in an apparent state of hibernation in the Chuckwalla Mountains of California, in December 1946, although naturalists may have been aware of torpidity in this species since the 1890's and native peoples probably knew of it even before then, the Hopi Indians' name for the bird being *Hölchko*, "the sleeping one". Since the late 1940's, investigations into the possible use of torpor by nightjars have been undertaken on both wild and captive birds of several species, including the Common Poorwill, the Common Nighthawk, the Whip-poor-will, the Eu-

During the breeding season, male Standard-winged Nightjars sport one of the most outlandish ornaments, not only within the Caprimulgidae, but of any bird. They possess highly modified second primaries, in this case consisting of a long bare shaft terminating in broad racquets. Both species in this African genus emit rapid high-pitched calls and they differ in their breeding biology from other nightjars studied. In particular, their mating system appears to be polygamous with several males attending display arenas that are visited by females. In the Standard-winged Nightjar, males circle potential mates while quivering stiffly bent wings in a slow undulating flight with their "standards" borne aloft. At rest, these bizarre feathers are held along the ground, perpendicular to the body. Despite considerable similarities, the two *Macrodipteryx* species are not thought to be particularly closely related because of discrepancies in plumage and wing shape.

[*Macrodipteryx longipennis*.]

ropean Nightjar and the Spotted Nightjar, but it seems that the Common Poorwill is the only nightjar that regularly utilizes this physiological capability to counter periods of low temperatures and poor food availability. Studies suggest that the Common Poorwill may become dormant when its body temperature falls below about 20°C and, quite remarkably, it can lower its body temperature to below 5°C during torpor and fly with a body temperature as low as 27.4°C, both values being the lowest recorded in any species of wild bird. In parts of its range, it is also known to enter prolonged periods of torpor, often referred to as hibernation, to help it survive poor weather during the non-breeding season. Other species that occur in more northerly or southerly latitudes or breed at higher altitudes do not appear to enter torpor regularly during bad weather, and usually overcome the shortage of food resulting from cold winters by migrating to warmer climes.

Most species have highly variegated plumages, with the upperparts and breast usually a variable mixture of brown, grey, white, black, buff, tawny, rufous and cinnamon, broken up with brownish or blackish streaks, spots or vermiculations. Such complex plumage patterns are essential for camouflage at the roost- or nest-sites, and the overall coloration is usually an adaptation to the local soil or habitat type. The underparts, which are visible only when a bird is in flight, generally tend to be buffish or off-white, barred brown. In many species, males have large white markings on the wings, tail and throat, the most extreme example being the White-winged Nightjar of South America, which has largely white wings, except for the inner wing-coverts and black primary tips, and an almost entirely white tail. In some species, white markings are present in both sexes. These markings stand out as strong visible signals during territorial aggression, courtship displays, and defence and distraction displays at the nest-site, but they are tucked away and hidden from view when birds are roosting, incubating or brooding. Two species appear to lack all forms of white markings, these being the Bahian Nighthawk of the Neotropics and the Afrotropical Standard-winged Nightjar, while several others, including the Brown Nightjar and some of the *Eurostopodus* species, have only the white throat patches. At hatching, chicks are usually covered in a pale down, but they quickly grow their first set of feathers, after which they generally look fairly similar to the adults.

Most nightjar species replace their plumage in one annual, post-breeding moult, and many attain adult plumage during their first winter, although a few remain in immature plumage until their second winter. Juveniles of a few species have only two partial moults during their first winter, and they tend to keep

their "second-year" plumage until the following annual moult. A complete moult is not always undertaken in one go, and some migratory species suspend a moult started on the breeding grounds and complete it at the wintering sites. Generally speaking primary moult is descendant, secondary moult is ascendant and tail moult is centrifugal, although the outermost tail feather (T5) is often renewed before the adjacent T4. Not all nightjars, however, share the same moult pattern. Some species within the genera *Caprimulgus* and *Macrodipteryx* have a secondary moult that commences at the outermost and innermost feathers and converges in the centre of the inner wing; some *Caprimulgus* and *Eurostopodus* nightjars have a serially descendant secondary moult; and another *Caprimulgus* species replaces the outer secondaries ascendantly and the inner secondaries centrifugally. Male Pennant-winged Nightjars have an unusual wing shape; they replace their primaries in a generally descendant sequence, although P4-P2 are moulted ascendantly.

Habitat

The vast majority of species within the family Caprimulgidae are permanently distributed in warm climates around the globe, but in many other regions where there are seasonal periods of hot and cold weather nightjars will move in to breed during the summer and depart again to escape the winter. They spend much of their time on the ground and usually need plenty of broken cover in which they can roost or rear their offspring. They occur in all types of habitat from deserts to rain forests, but semi-open country with trees and bushes is possibly preferred throughout the entire range, and areas where there is at least some kind of surface water are frequently occupied.

Nightjars can be found at all altitudes from sea-level, where some occur on or near beaches and shorelines, up to about 4200 m. Species of the more mountainous regions include Archbold's Nightjar of New Guinea, and several species in South America, such as the Roraiman Nightjar which is endemic to the "tabletop" mountains of the Pantepui region of southern Venezuela and north-west Brazil, and the Andean trio comprising the Rufous-bellied Nighthawk, the Swallow-tailed Nightjar and the Lyre-tailed Nightjar.

Deserts and semi-deserts with very little vegetation would appear to be among the poorest of places for nightjars, yet several species have adapted to living in the harsh conditions on offer there. These include the Egyptian Nightjar of Africa and

While the long wings and tiny feet of nightjars are indicative of their predominantly aerial habits, they roost and breed on the ground. Most nightjars frequent scrubby or bushy habitat, choosing open spaces in which to nest. Only a few species inhabit dense forests, nesting and roosting on leaf litter and generally feeding above the canopy.

Even within species, however, habitat choice is varied. The European Nightjar, for example, breeds on heaths and moorlands, young forestry plantations, chalk downland, scrubby steppes, stony hillsides, shingle banks, sand dunes and deserts, then spends the non-breeding season in the savannas, Acacia woodlands and highlands of Africa. It tends to avoid urban areas, mature forests, treeless plains and mountains, although it has been recorded up to 2800 m in the breeding range, and 5000 m in the Afrotropics.

The Star-spotted Nightjar is locally common in parts of East Africa, notably Ethiopia and northern Kenya, frequenting stony grassland and black laval deserts. In appearance, it is quite similar to the Plain Nightjar (*Caprimulgus inornatus*), with which it is thought to form a superspecies. Although the breeding ranges of these two forms narrowly overlap, reproductive isolation is presumably maintained by their very different vocalizations.

Asia, the Afrotropical Golden Nightjar, and possibly Vaurie's Nightjar of central Asia. Savannas and other grasslands, including areas with a composition nearer to that of a swamp or marsh, are inhabited by a few specialized nightjars; these include two extremely uncommon Neotropical species, the Sickle-winged and White-winged Nightjars, and the more widespread Afrotropical Swamp Nightjar. Species found in grasslands often seem to prefer areas where there are low structures such as bushes or termite mounds to perch on or to sing or display from. However, grasslands are often rather unstable environments which may be subjected to fires, flooding, trampling by large herbivores, or destruction for agricultural purposes, and the nightjars which live in them may frequently be forced to move to other regions.

Some species are often found in rocky or boulder-strewn terrain and at least two, the Neotropical Blackish Nightjar and the Afrotropical Freckled Nightjar, are known regularly to lay their eggs directly on rock surfaces. Other species, such as the Buff-collared Nightjar in Central America and Salvadori's Nightjar of Sumatra and Java, spend part of their time near cliffs, where they use the cliff faces to hunt from. In many regions, nightjars will frequent rivers and streams, and in South America species such as the Sand-coloured Nighthawk and the Ladder-tailed Nightjar are highly adapted to roosting and breeding on the sandbars and riverbanks exposed by low water levels during the dry season. Many of the world's nightjars, however, especially *Caprimulgus* species, actually occur in a wide variety of habitats and are often found in regions with a mixture of open ground, grassland, bushes, shrubs and trees. Others have taken to woodland and forests, where they prefer clearings and openings, the edges of roads, tracks or paths, or the borders and edges of the woodlands themselves.

As a general rule, nightjars tend to shy away from man-made habitats and usually avoid large urban areas, dense stands of forestry, agricultural country with few trees and little or no ground cover, and intensively farmed regions. A few species, however, will always exploit new opportunities as they arise, and some are frequently encountered in seemingly alien environments. Artificial lights, animal corrals or concentrations of livestock often attract large numbers of insects at night, and hunting nightjars soon learn to take advantage of such localized food sources. In North America, the Common Nighthawk is certainly not afraid of towns and cities and regularly nests on flat, gravel-topped roofs in some areas, frequently catching moths and other insects attracted to the light of street lamps. Roof-nesting has also been recorded for species in South America, Europe, Asia and Africa, albeit on a much smaller scale than in the Common Nighthawk.

Migratory species, which can cover huge distances between their breeding and wintering grounds, are always likely to turn up in atypical situations, often as a result of exhaustion or disorientation.

General Habits

Nightjars are secretive, nocturnal birds which are most active at dusk and dawn and during periods of strong moonlight, although a few species, such as the Common, Lesser and Antillean Nighthawks, can be equally alert at certain times during the day. Most species tend to leave their roost-sites at or during the twilight period of dusk, although during dull and overcast weather conditions many birds can often be seen slightly earlier, while others are more nocturnal and do not become active until well after dark. At certain times, especially when there is plenty of moonlight or when there are chicks to be fed, they can also be active throughout much of the night. They almost always return to their roosts before dawn.

Most nightjars usually roost on leaf litter on the ground, but they will also rest on bare soil, sand, pine needles, rocks, boulders, tree stumps, logs, roots and branches in trees. Some birds occasionally roost on artificial surfaces such as the roofs of buildings, or on man-made materials on the ground such as cardboard or sacking. Whatever site is chosen, it is usually somewhere where they can use their cryptic plumage to blend in with their surroundings and where they have a good view of any approaching danger. Nightjars tend to have several favoured roost-sites within their home range and will often use one site day after day, but they nearly always change sites once they have been disturbed. Nightjars often roost alone, although pair-members occasionally roost together, and in some regions, especially during the non-breeding season, many species often roost semi-colonially at favoured sites.

Roosting nightjars often awaken for short periods during the day, and they will then sit upright, preen, stretch their wings or gape widely, an action which looks remarkably like a big yawn! They may also move short distances, especially if they have been roosting in direct sunlight for too long, move around to face the sun, thereby reducing their tell-tale shadow, or move away from cooler, shaded spots to sunbathe. If danger approaches, a roosting bird immediately assumes a "vanishing" posture by slowly flattening itself to the ground, lowering its neck, head and bill, and closing its eyes until they are almost fully shut. While in such a position, nightjars are extremely alert and actually keep

The Collared Nightjar, one of two members of the family found on Madagascar, is a scarce bird largely restricted to the eastern humid forests. Its taxonomic placement perhaps deserves further study, since its bold, distinctive markings and unusual behaviour suggest that it might belong in a separate genus. Although it generally prefers denser, more continuous forest than most nightjars, it has also recently been discovered inhabiting brush and mangroves in the west. Individuals hawk for insects, either above or below the canopy, and have been recorded sallying repeatedly from emergent bare branches. It appears to be oddly silent for a nightjar and no song has ever been described, a circumstance which exacerbates the considerable difficulty of locating the species. It is most easily encountered in some of the better known protected areas, such as the Perinet-Analamazaotra Special Reserve, where regular roosting sites are known by local guides. Although it sometimes breeds on the ground, nests are also positioned fairly high in epiphytic or free-standing ferns. This behaviour is presumably an adaptive response to high predation rates, although in Madagascan forests snakes appear to be the only potential egg thieves sufficiently abundant to produce this effect.

The Nacunda Nighthawk is a large Neotropical species that occupies a monotypic genus. It spends much time on the ground, often walking upright and standing rather than sitting on relatively long, robust legs, in comparison with the tiny tarsi and feeble feet of most nightjars. Like several other nighthawk species, it is partially diurnal, regularly gathering in large feeding or migrating flocks high over open country. It is a summer visitor to southern portions of its range, occasionally straggling to Patagonia in the austral summer.

watch on whatever is going on around them, through the tiniest of slits between their eyelids. Should the potential threat approach too closely, a roosting nightjar immediately takes flight, flies away from the roost-site and quickly re-alights, where it either remains alert or once again adopts the flattened posture. If detected, nightjars flushed from their roost during the day are frequently mobbed by other birds, possibly because of their resemblance in shape to small birds of prey or parasitic cuckoos, and they are then at risk from predators such as hawks or falcons. If seen at dusk, nightjars leaving their roost also attract attention from other birds, or even bats, and may be preyed upon by larger species of owl.

Nightjars are mainly aerial feeders (see Food and Feeding) that carry out most of their hunting during their main activity periods at dusk and just before dawn. Normally, they have several relatively inactive spells during the night, and often sit on roads, tracks or paths or in other open spaces, or, in the case of some species, perch high up in trees. They sometimes hunt from these resting places, usually by making short flycatching sallies after passing insects, but quite often they will just rest or preen. While preening, nightjars maintain and waterproof their plumage, using the bill to transfer oils from down feathers on the breast and above the tail; the uropygial gland tends to be rather small. Some species occasionally dust-bathe, although such behaviour is poorly documented.

They often drink water, preferring to take it from the surfaces of lakes, ponds and slow-moving rivers rather than from fast-flowing waterways. Some species will also drink from artificial sites such as cattle troughs and swimming pools, especially in regions with very limited or no natural water supply. They usually drink in flight, normally by gliding low over the water surface with their wings and tail held up, and either "trawling" with an open bill or repeatedly dipping the bill into the water. Another, more hesitant, approach is to descend to the water in a series of short hovers before drinking and flying off. Some species, such as the Lesser Nighthawk, will also alight at the water's edge and drink with a "bobbing" action of the head and neck.

As a rule, these are highly inquisitive birds. They will often investigate intruders within their territory by approaching fairly closely and hovering nearby, although potential predators such as owls, foxes, cats and snakes are frequently mobbed or chased. Males holding territory are also fairly aggressive towards other

males of their own species, and will harass or even fight intruders to drive them away; such behaviour is usually commoner at the beginning of the breeding season.

Nightjars remain among the most poorly known of all birds and are difficult to observe, yet radio-tracking studies and the use of image-intensifying equipment are beginning to reveal some secrets of the behaviour of at least a few species.

Voice

Although nightjars generally seem to be rather silent, mysterious birds, they actually have quite a large repertoire of calls and can be particularly vocal at certain times, especially during the early part of the breeding season. On the other hand, they are often silent for much of the rest of the year. The main vocalizations of all species appear to be the advertising calls or "songs" of the males, which are given from a perch, in flight, or from the ground. Some species also make mechanical, clapping or "booming" sounds with their wings (see Breeding).

The most obvious sound given by the majority of species is the main advertising call of the male, which usually serves to proclaim a breeding territory and attract a mate. Although such calls play a vital role in the life cycles of all species of birds, they are especially important to nightjars, as nearly all of their main activities take place at night. Males often choose to "sing" or call from an elevated perch such as a tree branch, fence post, overhead wire, rooftop or boulder, but some sing or call in flight, often high above the ground, and some sing from the ground itself. Nightjars appear to sing with their bill closed, and project their calls in different directions either by turning about on one song-perch or by flying around their territory and calling from different places.

Advertising calls can carry a long way but are less audible in bad weather, and nightjars are often silent or sing only briefly in adverse conditions. Peak calling times for most species are dusk and dawn, although nightjars often sing throughout the night when there is plenty of moonlight. They tend to sing more strongly prior to and at the beginning of the breeding season, and sing much less often once a pair-bond has been formed or the eggs have been laid. Some species, such as the Common Nighthawk,

Despite the proximity of Madagascar to the African mainland, there are many clear links between the Malagasy and Asian avifaunas. It is thus less surprising that the Madagascar Nightjar, endemic to the Indian Ocean islands, looks and sounds remarkably like the Indian Nightjar (*Caprimulgus asiaticus*). Like most nightjar species it possesses elongated and extremely tactile rictal bristles around the bill.

These feathers are attached to special muscles in the skin and are presumably related to its nocturnal feeding habits. It is the commonest nightbird in Madagascar, occurring in almost all habitats on the island except humid forest where it is replaced by the Collared Nightjar (*Caprimulgus enarratus*).

It frequents lighter woodland, plantations, cultivation and even urban areas where it has been recorded nesting on the roofs of buildings. The densest populations, however, are found in the spiny forests of the south and south-west, a distinctive dry habitat characterized by baobabs and strange *Didierea* trees. In this area, large numbers congregate after rain to feast on dispersing termites, and they frequently fly out over the sea at dusk, feeding on flying insects low over the Mozambique Channel.

[*Caprimulgus madagascariensis*, Berenty Reserve, Madagascar.

All nightjars are agile and buoyant fliers, primarily because of the very large wing area in relation to their body weight, and skillful adjustments to the spread and angle of the tail which acts as a rudder in flight. This manoeuvrability allows them to pursue and capture highly mobile flying insects. The Nacunda Nighthawk has more rounded wings than most nightjars and its flight action is noticeably looser and more erratic. It is sexually dimorphic, the female having a less extensive area of white at the base of the primaries and more brown bars on the belly. The white patches on the wing and throat form conspicuous visual signals and are present in many nightjar species.

frequently give their advertising call during the day, and even some of the most nocturnal species may sing briefly if disturbed from their daytime roost.

Many species have large white throat patches, which are generally hidden by the surrounding throat feathers when a bird is roosting or at the nest-site. When singing, however, these patches are prominently displayed and are puffed out at each call note, and at close range they serve as a visual signal to potential mates or competing males. The females of some species are also thought to give similar calls to the advertising calls of their mates, although the exact reason for this has yet to be identified.

Several different groups of advertising calls are recognizable within the Caprimulgidae, the most remarkable being the monotonous sounds that are often referred to as "churring" and which are produced by repeating a long series of often identical notes very rapidly. Although it was this eerie sound emanating from the undergrowth at dusk that gave these birds their English name, such calls are in fact given by only a handful of *Caprimulgus* species in Europe, Africa and Asia. The "churrs" vary from long, evenly pitched series to others that vary in pitch or are interspersed with other call notes. One Neotropical *Chordeiles* species, the Lesser Nighthawk, has a song that could be interpreted as a slow churr, although it is more often referred to as a trill, and this gave rise to its alternative English name, the Trilling Nighthawk.

Perhaps the commonest types of nightjar advertising calls are the whistled forms, which are probably given by the majority of species. Whistled songs vary greatly and may be rather simple, such as those given by some of the *Nyctiphrynus* poorwills or certain *Caprimulgus* species such as the Band-winged Nightjar or the White-tailed Nightjar. At the other end of the scale, whistled songs may be more complex, and range from those given by species such as the Chuck-will's-widow and the Whip-poor-will, which appear to sing their own names, to the more musical whistles of species such as the Fiery-necked and Abyssinian Nightjars.

Other varieties of advertising call include those which resemble repeated knocking sounds, as given by species such as the Red-necked, Large-tailed and Swamp Nightjars; those which sound like a ball bouncing on a hard surface, as given by the Indian, Madagascar and Sulawesi Nightjars; and high-pitched, insect-like

or bat-like twitterings, as given by the two *Macrodipteryx* species, the spectacular Standard-winged and Pennant-winged Nightjars of the Afrotropics. At least two species of *Eurostopodus* nightjar, the Spotted and the White-throated Nightjars of Australasia, have songs consisting of a series of "bubbling" notes.

Many species also have distinct flight calls which differ significantly from the main advertising call and are often given at times of contact with other birds of the same species. Contact calls vary greatly between species but often consist of clucking, croaking, chattering, twittering or whistling sounds. Nightjars utter a variety of other calls at all stages of their life cycle, especially at the nest-site, these ranging from soft murmurings, cooings and single call notes to churrs, rattles, squeaks, nasal "pinks" and throaty hisses. Chicks frequently make soft peeping or cheeping sounds, although they immediately become silent at the first sign of danger.

The most striking of all calls given by nightjars is a loud, guttural hissing sound that slowly rises in pitch and volume as the huge gape is opened. Such calls are always given in circumstances when the individual bird feels threatened, and similar sounds appear to be common to all members of the family in the same situations. Although usually uttered during defence or distraction displays at the nest-site, where they are intended to frighten off potential predators, they are also frequently given when a nightjar is handled by humans. Feathered, unfledged chicks will also emit this sound when cornered.

Food and Feeding

Nightjars are generally insectivorous feeders that hunt by sight and take a wide variety of prey. Their food is composed mostly of night-flying, winged insects which are captured and swallowed in flight, although many species also take insects from surfaces such as leaves, branches and logs, and some occasionally take prey items from the ground. This diet has enabled the family to occupy a wide range of habitats, and feeding nightjars have few competitors apart from bats.

Details of the dietary requirements and foraging behaviour of the Caprimulgidae are available for only a few well-studied species, such as the European Nightjar and the Common

The Sand-coloured Nighthawk is probably the most diurnal and gregarious of all nightjar species. It is highly adapted to riparian habitats in the Amazon basin, sometimes occurring near villages and clearings in forest but rarely straying far from water. While other nightjars tend to be encountered as solitary individuals or pairs, this species feeds, roosts and nests communally, usually on riverbanks and sandbars beyond the reach of most terrestrial predators. Flocks of up to 50 individuals are regularly observed foraging over rivers while colonies of more than 200 pairs have been recorded, often adjacent to nesting groups of Black Skimmers (*Rynchops niger*), Large-billed Terns (*Phaetusa simplex*) and Yellow-billed Terns (*Sterna supercilialis*). Males display near the colonies, walking towards females then stretching horizontally with wings raised to reveal the conspicuous underwing pattern. Their eggs or chicks are predated by a variety of raptors and are often harvested by local people as a seasonal supplement to the local protein intake.

Nighthawk. Most of the information on food taken by the members of this family comes from the analysis of stomach contents, either from birds taken for museum specimens or from road casualties. Prey items range in size from the smallest of gnats and mosquitoes to fairly large hawkmoths and locusts, although larger insects are presumably easier to hunt visually and are more beneficial in terms of nutrition gained to energy expended. On the wing, nightjars usually take numerous moths, beetles, flies, mantids, bugs, cicadas, lacewings, caddisflies, mayflies, damselflies, dragonflies, winged termites and ants, wasps, mosquitoes, gnats, cockroaches, grasshoppers, locusts, crickets and occasionally butterflies. Prey items taken from leaves, branches or the ground include flightless glow-worms, moth larvae, locust nymphs, caterpillars, small bivalves, earwigs and spiders, while insect egg cocoons, mites, small pieces of wood and vegetation, small seeds, earth and grains of sand are also ingested, in some cases no doubt accidentally. Gravel, grit, pebbles and stones are also swallowed, sometimes deliberately, and possibly aid the breaking-up of indigestible animal matter, which is later regurgitated in pellets. In Asia, the food of the Indian Nightjar in winter is documented as including *Euphorbia caducifolia* flowers and small mice (*Mus cervicolor*), while in North and Central America the Chuck-will's-widow is known to take small birds such as hummingbirds, swallows, warblers (Parulidae) and sparrows (Emberizidae).

Most species forage mainly at dusk and dawn, and their extremely agile and buoyant flight is constantly interrupted by sudden twists, turns, wheels, rises and descents as they spot and chase after prey. With such wide gapes, nightjars are often thought to trawl for insects by flying around with their mouths open, especially as prey items as small as mosquitoes are often taken, but generally they just snap at insects when they come within range. Most nightjars also have elongated rictal bristles around their gapes, and these sensitive, modified feathers probably help to locate or funnel insects into the mouth. Between chases, they frequently glide around with their wings held in a "V" shape above their body. While hunting, some nightjars also occasion-

ally hover and swoop down after prey. Some species, such as the *Chordeiles* nighthawks, often hunt in a faster, even more erratic flight that is also interspersed with short glides. Nightjars occasionally forage during daylight, especially in very overcast conditions, although such behaviour usually takes place just before dusk or just after dawn.

Hunting nightjars will usually take food in the air space between ground level and above treetop height, although some species, such as some of the larger nighthawks, often forage very high up at about 150-175 m above ground. Nightjars usually forage alone, but in many regions, especially during migration periods and the non-breeding season, up to 20 or more birds of more than one species have been recorded gathering at good food sources, such as around grazing animals, animal corrals, lights or fires, or at insect swarms or termite emergences. Some species of nighthawk, such as the Common and Lesser Nighthawks, often forage in large flocks of several hundred birds.

Later in the night, when there is less available light than at dusk or dawn, nightjars sometimes change their foraging strategy to a wait-and-see technique, by flycatching from a perch or from the ground. During this method of hunting, a nightjar leaves its perch when an insect comes within range, pursues it in a short, acrobatic flight and then returns to either the same or a nearby perch. Flycatching nightjars possibly use moonlight or the night sky to backlight their prey when it is too dark for prolonged aerial foraging. Species that occasionally take insects from foliage or branches do so by hovering briefly, plucking off the prey item in the bill and then flying off.

Nightjars feed on the ground by running and darting after food, although such behaviour is possibly not common in the majority of species. For a few species, however, ground feeding can be quite important at certain times of the year. The Chuck-will's-widow, for instance, undergoes a rapid moult on the breeding grounds, during which it is often unable to fly strongly, and the ability to hunt prey on the ground is obviously a valuable survival asset at this time. The Pauraque has relatively long tarsi, suggesting that it is more strongly adapted to a terrestrial life

The Rufous-cheeked Nightjar is an intra-African migrant, breeding in southern regions, including South Africa, Zimbabwe, Angola and Namibia, and spending the non-breeding season in West Africa, with the majority of birds visiting Cameroon and Nigeria during the austral winter. During courtship in September and October, males clap their wings in display flights over wooded savannas, Acacia scrubland and the sparsely vegetated semi-deserts of the Karoo, Kalahari and Namib. The species is closely related to the Sombre Nightjar (*Caprimulgus fraenatus*) of north-east Africa with which it was previously considered conspecific.

[*Caprimulgus rufigena* rufigena, Brandvlei, Northern Cape, South Africa.
Photo: Peter Steyn/Ardea]

The genus *Eurostopodus* contains seven species that are often termed the "eared-nightjars", although only two of them possess elongated superciliary tufts. They differ from most other members of Caprimulgidae in lacking prominent rectal bristles and any traces of white in the tail, and recent genetic research reveals that they might belong in a separate sister family, the *Eurostopodidae*.

Continued study might well support the further division of this new family into three genera as there is considerable variation in morphology, ecology and vocalizations within the group. The nominate race of the White-throated Nightjar usually breeds in dry forest, heathland or the fringes of humid forest in Australia, with southern populations wintering as far north as New Guinea. The dark Solomon Islands race *nigripennis* nests on or near beaches, while the New Caledonian form *exul* is known from only one specimen taken in lowland Melaleuca woodland in 1941. It has not been recorded since despite considerable efforts to locate it. Both *exul* and *nigripennis* are highly divergent from *mystacalis* and might prove to justify recognition as separate species, in which case they would both be considered threatened. Nest defence, at least in the nominate subspecies and many other nightjars, takes the form of a threat display during which the adult stands upright, stretches its neck and wings and spreads its tail. This sometimes develops into a distraction display wherein the adult either hisses and retreats slowly or flutters to feign injury.

Dawn Frith]

All nightjars have very small, weak bills and yet their gape is enormous due to a highly specialized spreading mechanism of the lower jaw which means that they can open their mouths both vertically and horizontally. This adaptation, along with the extreme sensitivity of their palate, presumably enables them to catch and consume large or mobile insects in flight. Most species, including the Red-necked Nightjar, also use this broad gape to frighten intruders during threat displays at the nest. While raising their wings and gaping they emit curious guttural hissing sounds.

[*Caprimulgus ruficollis ruficollis*, near Páncas, Tagus Estuary, Portugal. Photo: Tony Tilford/Oxford Scientific Films]

style than other nightjars, as may also be the case of the *Siphonorhis* poorwills, though unfortunately ground-feeding by all three of these species is very poorly documented.

During the non-breeding season, many species can have rather a large home range in which to forage, but breeding territories are often smaller, and it has been found that nightjars sometimes travel distances of up to 10-15 km outside the territory to feed in areas with plenty of food. They will also drink when water is available (see General Habits).

In British Columbia, Canada, several recent studies have revealed that Common Nighthawks, when foraging, can fly at speeds of up to 5.3 m per second, pursue up to 18-19 items of prey per minute, capture more than one insect at a time, and spend up to 5.3% of each 24-hour period foraging. Studies of the Whip-poor-will, also in Canada, have shown that this species is generally lunarphilic, its activities and bouts of foraging being most intense during periods of twilight and bright moonlight, and it is highly probable that this also applies to most nightjar species. The same study in Canada also suggests that, although many insects are lunarphobic, being less active during twilight and in bright moonlight, the higher levels of light available during these periods probably help a foraging Whip-poor-will and provide an opportunity for a greater capture rate, despite there being less prey available. Studies of European Nightjars have demonstrated that while foraging they can take up to 12 prey items per minute, but if hunting using the flycatching technique they may make up to 28 sallies over a 15-minute period and pursue up to 31 items of prey.

Breeding

The ecology of nocturnal birds is difficult to study, and the breeding behaviour of almost all nightjar species remains little known and poorly documented. With a few exceptions, nightjars are

generally territorial, ground-nesting birds that have a monogamous breeding strategy, with pairs mating for life, or breeding together for one season only, or occasionally even changing partners between first and second clutches. In the majority of species, breeding pairs usually nest by themselves within their own territories, but some species occasionally breed semi-colonially, while a few sometimes nest in colonies. In some regions, breeding appears to be linked to particular phases of the moon, while in others it is influenced by the annual rains. Both sexes take active roles in parental care, although females usually spend more time at the nest-site during the day. The two Afrotropical *Macrodipteryx* species, the Standard-winged and the Pennant-winged Nightjars, have a different breeding strategy from that of other nightjars and are possibly polygamous.

The breeding cycle usually commences with males establishing a territory, which they do by "singing" from different points around an invisible boundary. Once a territory has been occupied, males generally defend it vigorously against other males, especially during the early part of the breeding season or before a pair-bond has been formed. The most common form of territorial defence is for a male to sing strongly towards a neighbouring singing male. Should two singing males be within visual range of each other, they may adopt an aggressive posture with their wings drooped and their tail fanned or raised in the air. The more extreme confrontations at territorial disputes involve physical contact, in which two males fly at each other while hitting out with their wings and bill-grappling. Fights of this sort can actually take place either on perches or in the air, and may end with both birds falling to the ground before they break off and go their own ways. Territory size varies from species to species and also depends on the amount of suitable habitat available to the local population. The smallest territories measure less than 1 ha in size, while the largest cover up to 40 ha or more, and, with habitat often dictating population densities in many areas, terri-

Nightjars often glide with their wings held in a distinctive "V" shape, a posture that they adopt when drinking in flight. This behaviour is perfectly illustrated by this series of photographs of a Common Nighthawk gliding low over the surface of a lake and "trawling" for water with an open bill. Although not the only technique employed by nightjars to drink, this is the most frequently recorded. They have also been observed dipping the bill repeatedly while hovering over water, or perching beside a water source and sipping at the surface. Nightjars tend also to bathe in flight, often using wind-driven rain which they fly towards then suddenly spread their tail, an action which stalls them in the air and pulls the body upright. They maintain this position with bouts of rapid fluttering while ruffling their rain-rinsed feathers. Common Nighthawks are indeed common over much of North America, migrating to South America in the non-breeding season, sometimes reaching as far south as Patagonia. They forage high over open country or water, occasionally in flocks of up to 300 individuals. Long-distance migration renders them prone to vagrancy and they are regularly recorded on the western seaboard of Europe in autumn after displaced individuals have inadvertently crossed the Atlantic.

[*Chordeiles minor*,
Texas, USA.
Photos: Tom Vezo]

Nightjars do not construct a nest as such, merely laying the clutch onto bare patches of ground, sometimes directly onto rock. The eggs tend to be whitish with a variable amount of brown, red or grey speckling. Traditional nesting sites are sometimes used year after year and most species nest alone in territories extending up to 40 ha. The Common Nighthawk generally follows this rule, but occasionally breeds in loose colonies, sometimes together with congeners. While nests of this species are most frequently placed in open country or woodland they have been recorded in the old nests of American Robins (*Turdus migratorius*) and on top of fence posts. Increasingly, man-modified environments are used too, such as the roofs of buildings or between the rails of railway tracks, incubating females apparently tolerating the trains regularly passing overhead.

[*Chordeiles minor*,
USA.

territories may be either far apart, side by side, or with boundaries that overlap in places.

Singing is also used to attract potential mates into the male's territory, and, once this has been achieved, males usually display to the females to try to establish a pair-bond prior to breeding. During courtship displays, the males of many species show off a series of prominent white markings on the throat, wings or tail (see Morphological Aspects), while some, such as those in the genera *Macrodipteryx*, *Hydropsalis*, *Uropsalis* and *Macropsalis*, deploy elaborate or elongated wing or tail feathers. Courtship rituals may be performed on the ground or on a perch, but more commonly they take place in the air.

During aerial courtship displays, some species, and especially the *Caprimulgus* nightjars, display their white markings during a gliding or "sailing" flight, with the wings held in a "V" shape above the body and the tail fanned at an angle. Many species, again notably male *Caprimulgus* nightjars, are also known to produce clapping or "whip-cracking" sounds with their wings. Common and Antillean Nighthawks display by circling high up, then diving through the air with their wings held in a "V" shape above the back. As they come out of the dive, they suddenly bend their wings downwards and produce a "booming" sound. A few species make other types of "mechanical" wing noise during their display flights: these include the Standard-winged Nightjar, which makes "frp" sounds, the White-winged Nightjar, which produces "frt" and short "tk" sounds, and the Sickle-winged Nightjar, which gives audible flaps and muffled "tuc" sounds.

The courtship of the Lyre-tailed Nightjar often takes place at communal display sites or leks, with several males calling and pursuing several females. Males also hover and move their elongated tail feathers to and fro. Male Long-trained Nightjars also display their enormously long tail feathers while courting females. They may display either from the ground, raising the tail to form a large white "V", or in flight, when the tail is fanned into an

inverted "V". Male White-winged and Sickle-winged Nightjars perform display flights around their territories by fluttering and gliding between exposed perches such as termite mounds, during which they use their uniquely shaped wings to produce the far-carrying mechanical sounds mentioned above.

Some courtship displays commence on the ground, with a male taking flight, circling and fluttering around the female, then alighting again nearby. During these short courtship flights, males often fly with their wings held level and rapidly quiver their wingtips. In the ground display of the Sand-coloured Nighthawk, the male stretches up, inflates his throat, fans his tail, sways from side to side and walks towards the female, before suddenly stretching horizontally, touching the ground with his inflated throat, and raising his wings to show off the underwing pattern. Male Scissor-tailed Nightjars often perform their courtship displays from open patches of ground, during which they stretch up their wings, suddenly close them to produce a snapping sound, and make little jumps into the air. Other displays, such as those given by the Puerto Rican Nightjar, often take place on tree branches or other elevated perches and often begin with a male and a female sitting parallel about 50 cm apart. The male may sing briefly while vibrating his body, drooping his wings and fanning his tail, then walk slowly towards the female. Copulation often follows a successful display. At the start of the breeding season, the males of many species usually roost alone within their territories. However, pair-members often roost together at the chosen nest-site prior to egg-laying, and once breeding is under way the male occasionally roosts close to the incubating female.

The two Afrotropical *Macrodipteryx* species both have display arenas, at which usually several males display to several females. The male Standard-winged Nightjar has a slow, undulating display flight during which he vibrates his stiffly bent wings, while his elongated second primaries, the flag-like "standards", float above and behind him. Pennant-winged Nightjars have two

types of courtship display. During their aerial displays, males glide around, often at treetop height, with their elongated second primaries, the "pennants", fluttering behind them, and are often followed by one or more females. For their other type of display, males alight on regular perches such as stones, termite mounds or even the ground, spread their wings and slowly circle around on the spot while vibrating their "pennants".

Nightjars usually prefer dry, open areas for nesting, and often choose nest-sites that are near or among vegetation, rocks, stones, logs or fallen branches, which typically offer some protection against the elements or predators. They do not build nests, and generally lay their eggs on leaf litter on the ground, or on bare soil, gravel or sand. Nightjars are often considered to make little scrapes in which to lay their eggs, but it is more likely that the small depressions which develop at the nest-site are caused by sitting birds and by the adults dislodging debris during change-over duties. Some species, such as the Freckled Nightjar and the Blackish Nightjar, frequently choose to nest on rocks or boulders, and lay their eggs on a thin covering of lichens, or on leaf litter or directly on the rock surface. The Semi-collared Nighthawk of South America may be unique among nightjars in that it nests in trees, laying its single egg in a branch hollow or at a fork. Two forest species for which few data are available are also thought to nest off the ground, at least on some occasions: the Brown Nightjar may lay its eggs on a palm frond, while the Collared Nightjar of Madagascar is known to nest in epiphytic ferns on tree trunks, or in the crowns of free-standing ferns, where the nest-site may be up to 1.5 m above ground. Nesting on the roofs of buildings is also well known and has been recorded for several species, including the Common Nighthawk and the Band-winged and Madagascar Nightjars, in different parts of the world. For the Common Nighthawk this is a common practice, and birds have been breeding on flat, gravel roofs in some urban areas of North America since at least the middle of the nineteenth century. Colonial nesters include the Sand-coloured Nighthawk, with up to 200 pairs often breeding close to each other on beaches and sandbars. Beach-nesting nightjars and nighthawks often lay their eggs close to the nests of other birds such as plovers (Charadriidae),

terns (Sternidae) and skimmers (Rynchopidae). Semi-colonial nesting is occasionally recorded, notably in the mixed-species associations of Common and Antillean Nighthawks. Some nightjars use the same favoured nest-sites year after year.

Nightjars generally lay clutches of only one or two eggs. Although three or four eggs have been recorded for a few species, such as the European Nightjar, these occurrences are extremely rare and are possibly the result of two females laying at the same site. In most species, the eggs are laid at intervals of 24-48 hours. Egg size ranges from about 22 x 17 mm in the Least Nighthawk to about 44 x 31 mm in the Great Eared-nightjar. Eggs are generally elliptical, smooth and whitish, although some species such as the Pauraque and the Papuan Nightjar often lay eggs with a pinkish or brownish ground colour. Markings of spots, blotches, freckles and scrawls may be blackish, greyish, brownish, reddish or lilac in colour, and eggs range from being completely unmarked to densely patterned, the latter especially at the fatter end. Having pale eggs enables a parent bird to locate them more easily at night, but the light colour may prove to attract predators during the day. Nightjars counter this, however, by sitting very tightly during the incubation period. Most species tend to be single- or double-brooded, although when conditions are favourable in tropical regions some may attempt to rear three broods in one season.

Eggs that are accidentally dislodged from the "nest" are occasionally moved back by the adult pushing them with its bill, but reports of nightjars deliberately carrying their eggs away from danger appear to be erroneous. After the eggs have hatched, however, pieces of eggshell may occasionally become stuck to the adults' legs or underparts, presumably with dried albumen, and this may give the appearance of eggs being carried.

The incubation period averages about 16-22 days in most species, the eggs hatching asynchronously. Chicks are covered in greyish, brownish, buffish or reddish down. Although fairly mobile from hatching, downy chicks are less cryptically coloured than their parents, and until the first set of feathers is grown they rely on the tight brooding behaviour of the adults for their protection. Although some chicks remain in the vicinity of the nest-

The Fiery-necked Nightjar inhabits the miombo and mopane woodlands of eastern Africa where it is locally common.

Like other nightjars, it does not make a nest, laying its eggs directly onto leaf litter amongst which the incubating adult is well camouflaged.

Like most nightjars it is often encountered sitting at night on the sandy roads that traverse its favoured habitat, easily picked out in car headlights at long range, due the glaring orange eye-shine.

Ardea]

This Philippine Nightjar is only a few days old and its juvenile plumage has only recently started to emerge on its wings. Nightjar chicks are semi-precocial, being fairly mobile immediately after hatching, and covered in dense grey, brown or buffy down. As they are particularly vulnerable to predation at this stage, and poor at maintaining body temperature, they are almost permanently brooded by the adults. Reptiles and terrestrial mammals are the most frequent culprits of losses at nightjar nests. While the effective crypsis of eggs and chicks often conceals them from these predators, it also results in unintentional trampling by large mammals including people.

[*Caprimulgus manillensis*, San Salvador Island, Luzon, Philippines. Photo: Doug Wechsler/VIREO]

site until they fledge, others will move considerable distances and frequently change locations each night; for example, young White-throated Nightjars may move up to 10 m each night until about 10 days of age, and up to 20 m per night after that until they fledge. Chick movements are triggered by the adults landing nearby and calling, the offspring responding by walking, running or hopping over to them to be fed. To be given food, the chick reaches up and grabs the parent's bill; the adult then feeds

it either by regurgitating balls of insects directly into its mouth or by letting the chick take the food from inside the adult's mouth. After feeding, the chicks are then brooded at the new site.

The first set of feathers starts to appear at about 5-7 days of age. The feathers grow quickly, and in their juvenile cryptic plumage the young can be left unattended for long periods and may not be brooded during the day, although one or both parents often roost close by. If threatened, young birds adopt the flattened

According to published data, the largest clutch known for the Jungle Nightjar of eastern Asia is two eggs, although this photograph suggests that more may sometimes be found. Clutches of more than two eggs have only been reported in a few nightjar species, generally those that have received the most intensive study. It is not known whether this rare phenomenon is a result of unusually high resource levels, or egg dumping by additional females. Nightjars usually begin to incubate immediately after the first egg is laid, which leads to asynchronous hatching. This occurs after 16-19 days in the Jungle Nightjar, and the chicks tend to fledge around 17 days later.

[*Caprimulgus indicus jotaka*, central Ussuriland, Russian Far East. Photo: Yuri Shibnev/VIREO]

As this female Red-necked Nightjar takes flight from her nest, her wings almost touch over her back. During display, wing mobility is used by males of this species, and of several others, as they produce sharp clapping noises by snapping their upraised wings together. Pursuing the female in fast, direct flight, the male Red-necked claps up to fifteen times in succession. At other times, he also sings with a series of hollow "kutok" notes, a familiar sound of Iberian summer nights. While the song appears to function in both territory defence and mate attraction, wing-clapping is reserved for these courtship displays.

[*Caprimulgus ruficollis*
ruficollis,

Albacete, Spain.

Photo: Francisco Márquez]

defence posture and sit completely immobile with their eyes shut, while the adult performs a distraction display. Sometimes they remain at the site at which they were originally disturbed, but often they move to nearby cover while the adult is performing its display. Older chicks often perform a threat display if cornered, during which they stand upright, stretch out their wings, gape widely and utter a throaty hissing sound (see Voice); at times they also attempt to escape by fluttering away along the ground. Nightjar chicks often take their first flights and fledge during their third week, and become independent at about 25-35 days of age, but many also remain in family parties with their parents for many weeks.

Nest protection takes several forms, of which the first can probably be considered the actual choice of nest-site. Perhaps the most extreme example can be seen in Common Nighthawks nesting on the roofs of very tall buildings, well out of the way of most ground predators. The second and commonest method is camouflage, incubating or brooding birds sitting tightly and relying on their cryptic plumage pattern to blend in with their surroundings. When danger threatens, defence displays are performed by some parents if they are reluctant to fly away and leave their nest-sites unattended. During such displays, the adult bird usually stands upright, stretches up its neck, spreads out its wings and tail, and backs away slowly, all the time gaping widely and uttering a guttural hissing noise. Defence displays are more commonly given when there are eggs. The last lines of defence are the distraction displays, which are more usually given after hatching. The most frequent type of distraction is the broken-wing display, in which an adult feigns injury and flutters along the ground or across low vegetation, with one or both of its wings outstretched and its tail fanned. If followed, the nightjar will continue the display for a distance before flying off. Distraction displays are sometimes performed in the air, with an adult nightjar labouring or fluttering about in flight and repeatedly alighting on the ground. Some nightjars also fly to an elevated perch and perform a distraction display from there, by drooping and fluttering the wings and fanning the tail. During all forms of distraction display, nightjars are usually extremely vocal and utter various croaks, clucks or guttural hissing sounds (see Voice).

The eggs and chicks of all species are highly vulnerable to predators, especially if left unattended for long periods. Their

main enemies include snakes, lizards, diurnal raptors, owls and a vast array of carnivorous mammals. In many regions, introduced predators such as feral or domestic cats and dogs, rats (*Rattus*) and mongooses (*Herpestes*) often take a heavy toll, and island or endemic populations are particularly at risk from this threat (see Status and Conservation).

It is often maintained that nightjars try to synchronize their breeding with particular phases of the moon, so that chicks hatch and grow during periods when their parents can forage in strong moonlight, and so that young birds become independent in similar conditions. Studies have shown that some species, such as the Whip-poor-will, the Fiery-necked Nightjar, the Mozambique Nightjar and the Pennant-winged Nightjar, do often synchronize their breeding with lunar phases, while the Common Nighthawk and the Common Poorwill apparently do not. In some species, especially migratory ones such as the European Nightjar, such synchronization may occur only accidentally, as factors such as the limited time available for breeding, failed clutches, predation and weather all play their part during a particular breeding season.

In tropical or subtropical regions, rainfall can also have a dramatic effect on the breeding success of many species. In South America, species such as the little-known Scrub Nightjar sometimes attempt to rear two broods in seasons of prolonged rains but may not breed at all in dry years. In Africa, many species commence their breeding cycles towards the end of the rainy season, while in Australia two *Eurostodopus* species, the Spotted Nightjar and the White-throated Nightjar, may not breed in regions where the preceding winter has been too dry. In more temperate zones, too much rainfall can have the opposite effect and be harmful to breeding success, especially when it occurs during the breeding season itself.

Movements

As with most of their activities, the movements and migrations of nightjars usually take place at night, and as a result they remain poorly known and difficult to study. In most species, the only real indication of movement comes from the increase or decrease of numbers at a given locality, and this may be simi-

Between May and August the evocative churring song of the European Nightjar drifts over heaths, moors and woods where females lay eggs on patches of bare ground and leaves. The timing of egg-laying is apparently sometimes synchronized with lunar phases in this species, purportedly to maximize the amount of moonlight, and thus foraging efficiency, while nestlings are developing. Research shows, however, that various other factors, such as weather and the time available for breeding, combine to reduce the likelihood of this occurring. Incubation and chick-care are undertaken almost exclusively by the female, identified here by the lack of white patches in the primaries and outer rectrices. Quite often, however, she will lay a second clutch when the first brood is only 10-16 days old. If so, the male takes care of the nestlings until they reach full independence 16-22 days later, and then helps with the second brood.

[*Caprimulgus europaeus europaeus*, south-east England. Photo: Jack A. Bailey/Ardea]

larly reflected in local road-casualty figures. Given that the Caprimulgidae occur in all of the world's faunal zones, it is not surprising that a range of different migration patterns has been identified, with many species having distinctly separate breeding and non-breeding areas. Some are either wholly or partially migratory, while others undertake only local movements, some are altitudinal migrants and a few are permanently resident.

Nightjars are almost entirely insectivorous and can survive only in areas with a plentiful food supply, so any seasonal reduction in the abundance of insects will often determine a need to move to other regions. Climatic conditions are probably the most important factors affecting insect levels, and, as most nightjar species generally do not use torpor to survive seasonal "lean" periods (see Morphological Aspects), they must migrate to more suitable areas at times when there are severe food shortages.

The real long-distance migrants are to be found among the species that breed in the northern temperate zone, usually in regions that experience cold winters. These include the Canadian and North American populations of the Common Nighthawk, which winter in South America; the European Nightjar, especially in its Asian populations, which mostly move across the Arabian Peninsula and winter in south-east Africa; and the eastern Asian populations of the Jungle Nightjar, which winter mostly in South-east Asia. All of these species try to avoid long sea crossings where possible, although individuals often turn up on islands, or on ships and oil platforms at sea. There is a record from the Aleutian Islands in late May of a vagrant Jungle Nightjar from eastern Asia, but it is the Common Nighthawk that is

especially prone to vagrancy, a number of representatives of this species, mostly immatures, having been recorded in Britain and elsewhere on the eastern side of the Atlantic in autumn, with one even reaching remote Tristan da Cunha.

Many other species undertake much shorter migrations, although the distances covered are often still quite impressive. In North America, some populations of species such as the Common Poorwill and the Whip-poor-will move south to winter in the southern states and in parts of Central America, while the Chuck-will's-widow also winters in the Caribbean and in the extreme north of South America. During the autumn, northern populations of the Lesser Nighthawk and the Pauraque also vacate their breeding grounds in the USA, but their migration routes and wintering areas in Central and South America are often obscured by the presence of resident, southern populations.

Central and South American nightjars remain largely unstudied, and the migratory status of many is still almost completely unknown. Some populations of species such as the Least Nighthawk undertake reasonably long-range movements, other species move around locally, some are largely or entirely resident, and a few high-altitude species such as those that breed in the Andes generally move down into the lowlands during the non-breeding season. The most obvious migrations, however, occur in the south of the continent and involve a whole range of species, from the relatively common Band-winged and Little Nightjars to the rare Sickie-winged Nightjar. All of these migratory forms have populations that move south for the austral summer, some breeding in regions as far south as Patagonia, and return north during the winter.

In Africa, the migratory habits and routes of some nightjars are reasonably well known. A few primarily East African species, such as the Nubian and the Plain Nightjars, have partially migratory populations that breed in parts of the Arabian Peninsula and the Middle East, while several more widespread species, including the Long-tailed and Standard-winged Nightjars, are intratropical migrants that move among the savannas between the Sahara Desert to the north and the forest zone to the south. Some more southerly species, such as the Fiery-necked and Mozambique Nightjars, have rather complex migrations that are often influenced by seasonal rains, while two others, the Rufous-cheeked and Pennant-winged Nightjars, are trans-equatorial migrants that are more open to vagrancy than all other Afrotropical species.

Several Asian species within the genera *Eurostopodus* and *Caprimulgus* are known to be migratory, at least in the more northern parts of their ranges, and in Australia some populations of the Spotted Nightjar and the White-throated Nightjar have north-south migrations that appear to take small numbers into New Guinea during the non-breeding season. The nightjars that breed in New Guinea, however, are generally not migratory, and this appears to be largely true of island species and subspecies throughout South-east Asia and westwards to the Indian Subcontinent.

Altitudinal migration is perhaps the least common strategy within the Caprimulgidae, since relatively few species occur regularly in high mountainous regions or in areas far above sea-level. Of those that do, probably the majority are found in the Andes of South America, and these include the Rufous-bellied Nighthawk, the Swallow-tailed Nightjar and the Lyre-tailed Nightjar, although details of their movements, other than possible nomadic post-breeding wanderings, have yet to be studied. Data concerning the ecology of Archbold's Nightjar, the highland species of New Guinea, are rather scarce and no altitudinal movements have so far been documented. Elsewhere, other species exhibit such be-

haviour only in some parts of their ranges, an example being the Abyssinian Nightjar population breeding in Saudi Arabia, which generally occurs at altitudes of 2000-3000 m on the Raydah escarpment along the western side of the Asir Mountains but may descend to 1200-1900 m during cold winters.

Relationship with Man

Nightjars are not only crepuscular and nocturnal, they are cryptic, secretive and often silent, and are extremely difficult to study, observe or even identify in the field. In many parts of the world, they are mysterious enough to have been the subject of numerous stories and tales over the years and often feature heavily in local folklore. From one of the oldest stories has arisen the colloquial name "goatsucker", and the term is still frequently used, even to this day.

The European Nightjar is one of the most widespread and commoner species and has probably had more contact with man than just about any other nightjar. With an entirely insectivorous diet, it tends to feed in areas with a good food supply; in the past, this often meant foraging around livestock, including goats, especially in places where the animals had been corralled for the night. During the summer, it would not be uncommon for at least some of the livestock to be in breeding condition or have newly born offspring, and females would therefore often have milk dripping from their teats. The shepherds and country people, seeing the shadowy nightjars around their animals at dusk and noticing the milk early in the morning, put the two circumstances together and believed that the birds were sucking milk during the night and that, as a result, their animals would eventually be sucked dry and go blind.

This particular piece of folklore dates back at least to the time of Aristotle or even earlier, and became widespread through-

Like all members of the family, the European Nightjar is an almost exclusively aerial feeder that hunts moths, beetles and many other flying insects by sight. Its nocturnal habits leave it with few competitors apart from bats, and it has been recorded capturing up to twelve food items per minute. During the breeding season, food is delivered to nestlings and fledglings in the form of mashed up insects regurgitated in balls. When the adult visits the nest, a hungry chick reaches up to grab its bill and begs. In response, the adult inserts food into the chick's mouth or holds it up for the chick to take. The size of item brought to the nest is related to the age of chicks, with well-grown young being delivered conspicuously large helpings.

After the initial downy phase, feathers first appear on young Large-tailed Nightjars after 5-7 days. This juvenile plumage resembles that of the adult and grows very rapidly, providing the chick with camouflage that reduces the risk of predation and allows it to be left for longer periods. Indeed, the adults stop brooding the chicks after about 14 days, but often roost close by. Fledglings tend to take their first flights in the third week of life, becoming fully independent at around 35 days old. This species is common and widespread in a variety of wooded and grassy habitats between Pakistan and Australia, where it quickly colonizes deforested areas.

[*Caprimulgus macrurus bimaculatus*, Singapore.
Photo: Rolf E. Kunz]

out the whole of Europe, often earning the bird names such as goat owl or goatsucker in English, *Ziegenmelker* in German, *kozodoi* in Russian and *chotocabras* in Spanish. Indeed, the legend of the goatsucker was so widespread and well known that it also formed the basis for the scientific genus name *Caprimulgus*, *capra* being the Latin word for a nanny goat and *mulgere* meaning to milk, a "*caprimulgus*" thus being a milker of goats.

With such a huge breeding range, it is not surprising that the European Nightjar also became the subject of other myths and legends, and in Britain alone strange beliefs and local names were commonplace. In some regions, it was often associated with a mischievous spirit of the dark called Puck, from which it possibly earned the local name Puckeridge. This name, however, might also have arisen from the belief that nightjars would strike young calves with their beaks and infect them with a disease, although the skin infection concerned was most probably caused by an egg-laying fly. In other areas it was given the name Gabble Ratchet, based on the legends of the Gabriel Hounds of the wild hunt, because, when unbaptized children died, their souls were thought to disappear into nightjars. Associations with bad omens also resulted in local names such as corpse bird, corpse fowl and litch-fowl, and similar names also came into being in other countries such as Germany, where in some parts it was called *Todtenvogel* or death bird.

Superstitious beliefs about nightjars also abound in many other countries around the world, especially in remote regions, and are often based around their unseen, nocturnal habits and their strange calls. In parts of North America, the Whip-poor-will was often associated with death, while in other areas it was linked with marriage, the number of successive times it called being the number of years a man would remain a bachelor. In some regions of South America, the number of successive call notes given by a nightjar was believed to be the number of years the person who heard them would live, while, in some areas along

the Amazon, nightjars were thought to be the souls of the deceased. In parts of Australia, some Aborigines believed that the Spotted Nightjar took away babies during the night. In Sulawesi, an even stranger mythology concerns Heinrich's Nightjar, which until recently was known only from a single museum specimen taken in 1931. Also known as the Satanic or Devilish Nightjar, it was given the scientific name *Eurostopodus diabolicus* apparently as a reference to the local belief that the call of this species at night was the sound it made as it took out people's eyes.

Nightjars have never really been hunted for food, at least in any great numbers, but the eggs of some species such as the Sand-coloured Nighthawk of South America may form an important seasonal part of local diets.

Status and Conservation

Although some nightjar species are widely distributed and appear to be fairly common, the majority are so poorly known that it is difficult to gauge accurately the impact that human activities are having on their populations. Habitat destruction probably poses the greatest threat to most species, and, even allowing for the fact that a few nightjars occasionally make use of artificial or urban landscapes, they are generally intolerant of environments that have been greatly altered. After dark, nightjars like to rest in or hunt from open spaces on the ground. Unfortunately, such spaces include roads and tracks where they frequently become casualties to an ever-increasing amount of traffic, birds being run over while their vision is impaired by vehicle headlights. Many species, particularly island endemics, are also suffering as a result of predation by introduced mammals such as rats and mongooses, and the widespread reduction of insect populations through pollution and pest-control methods appears to be affecting nightjar numbers in some re-

Sadly, the European Nightjar has decreased substantially in many portions of its range.

Reduced grazing of heathlands and pastoral woodlands accelerates vegetational succession, while conversion to cultivation eliminates them altogether. These factors have reduced nightjar numbers and are compounded by catastrophic reductions in the populations of large insects, such as cockchafers (*Melolontha melolontha*), since the widespread application of pesticides on farmland.

Fortunately, modern afforestation practices provide suitable habitat for the species and although this only applies for 15-20% of the forestry cycle it has helped to maintain nightjar populations in areas from which they might otherwise have disappeared.

gions. Officially, six species are currently listed as globally threatened, three of which are classified as Critically Endangered, and a further eight species are considered to be Near-threatened. However, with new species and populations still being discovered, it is clear that much more information is needed in order to determine the true status of all nightjars before it becomes too late for some.

In Europe, the widespread and reasonably well-studied European Nightjar is decreasing in numbers and range in many regions. Although these declines were originally considered to be restricted to the northern and north-western limits of its breeding range, it is now clear that the species is also suffering throughout central and eastern Europe. The main reasons for the declines are generally considered to be habitat loss and pesticide use, but not all is doom and gloom, as in some countries such as Great Britain the conservation of the remaining heathland habitats and better management of woodlands and young conifer plantations has seen a small increase in numbers during the last 10-15 years. The only other European breeding species, the Red-necked Nightjar, is experiencing similar threats, and in the Mediterranean region its habitat is disappearing at an alarming rate often as a result of the ever-increasing tourist industry. The Egyptian and the Nubian Nightjars have small breeding populations just outside Europe but still within the Western Palearctic, and they, too, have declined through human pressures.

In North America, species such as the Common Nighthawk, the Common Poorwill and the Whip-poor-will are not uncommon in places, but appear to be undergoing declines at the northern limits of their breeding ranges. Of these species, the Common Nighthawk is generally the most tolerant of urban habitats and frequently occurs in towns and cities. The Lesser Nighthawk and Chuck-will's-widow are apparently faring better than most and small increases in numbers or expansions of range have been documented for some regions. The Buff-collared Nightjar is pri-

marily a Central American species with just a toehold in the extreme south-western USA; here it is officially classed as endangered, and protection measures include a complete ban on the taking of specimens for museum collections. Further to the south, this poorly known species is regarded as reasonably common in Mexico, but it is rarer in the south of its range. The Pauraque also has a small North American population in Texas, but it is primarily a Neotropical species that is generally regarded as common to fairly abundant in many parts of Central and South America.

The complexity, variability and general similarity of their plumage renders many nightjar species difficult to separate even with the benefit of prolonged views.

The combination of a white fore-wing bar, white secondary tips and a short, square tail distinguish the male Mozambique Nightjar from all other species, but these helpful features are less evident in females and immature birds.

[*Caprimulgus fossii welwitschii*,
Mvuu Camp,
Liwonde National Park,
Malawi.
Photo: Peter Steyn/Ardea]

The Long-trained Nightjar is restricted to the Atlantic forests of south-east Brazil and north-east Argentina, where it is scarce and local. During display, the male's elongated rectrices are fanned in flight, or raised while perched, to form a distinctive white "V".

The species is currently considered Near-threatened and is gradually declining as a consequence of deforestation.

To complicate conservation strategies for the species, it is an altitudinal and latitudinal migrant requiring suitable forest-edge habitat in both the breeding and non-breeding range.

[*Macropsalis forcipata*, Nova Petropolis, Rio Grande do Sul, Brazil. Photo: Haroldo Palo Jr/ NHPA]

The remaining species in Central America are, for the most part, not thought of as immediately in danger, although most are little known and infrequently seen. Several are endemic to the region, however, including two *Nyctiphrynus* poorwills and three *Caprimulgus* nightjars, and as such their populations should be closely monitored where possible. The Eared Poorwill, a Near-threatened species, and the Tawny-collared Nightjar are found only in Mexico; a disjunct population of the Ocellated Poorwill of the race *lautus* occurs in parts of Central America; the Dusky Nightjar is confined to upland forests in Costa Rica and western Panama; while the Yucatan Poorwill and the Yucatan Nightjar are, as their names suggest, largely restricted to the Yucatán Peninsula in south-eastern Mexico.

The Caribbean islands hold five endemic species which, in addition to habitat and agrochemical threats, also face the additional spectre of predation from alien omnivores and carnivores such as rats, mongooses and cats. Two of these species, the Puerto Rican Nightjar and the Jamaican Poorwill, are officially listed as Critically Endangered, and the latter is generally regarded as being the only nightjar species to have become extinct within the last 150 years. Although not positively seen since the mid-nineteenth century, all may not be lost for this always rare poorwill, since unidentified nightjars have been sighted on the island in recent years, and ornithologists need look only as far as the Puerto Rican Nightjar to see how the fortunes of these secretive birds can be dramatically different from what was previously thought. Described from a specimen taken in 1888 but not recognized as a distinct species until 1919, the Puerto Rican Nightjar was often thought of as extinct until it was rediscovered in 1961. By the early 1990's an estimated population of up to 2000 birds was thought to exist in a few dry cordillera forests in south-western Puerto Rico. Of the other endemics, the Hispaniolan Nightjar and the Near-threatened Least Poorwill are found only on Hispaniola, and the Cuban Nightjar occurs only on Cuba and the Isle of Pines. Although none of these is considered to be in immediate danger, their true status will need to be carefully monitored.

With more nightjar species than any other continent, it is not surprising that South America has more species at risk than anywhere else. Only six have so far been catalogued as being threatened or Near-threatened, but many more are poorly known and

possibly in serious trouble. The White-winged Nightjar is classified as Critically Endangered, but, although until recently it had not been seen for over 100 years, the new or potential populations lately discovered in parts of Brazil, Bolivia and Paraguay suggest that this beautiful nightjar is possibly not so rare as was previously thought. The Near-threatened species include: three endemics, namely the Choco Poorwill of western Colombia and western Ecuador, the Roraiman Nightjar, which is restricted to

Several anomalous features, such as tough, curved primaries and the apparent production of mechanical noises rather than vocalizations, suggest that the White-winged Nightjar might belong in the genus *Eleothreptus* along with the Sickie-winged Nightjar (*E. anomalus*); both species inhabit the grasslands and sparsely vegetated cerrados of South America where they are uncommon. The White-winged is only known from three widely separated sites. Adequate conservation of these legally protected areas is vital, as are further surveys in intervening regions. This species habitually perches on ant-hills or termite mounds.

[*Caprimulgus candicans*, Mbaracayú Reserve, Paraguay. Photo: K. Zyskowski/ VIREO]

After its discovery in 1888, the Puerto Rican Nightjar went unrecorded for many years and was assumed to be extinct until its rediscovery in 1961. Recent surveys have concluded that around 2000 individuals survive at a few forested sites on the coast and cordilleras of south-west Puerto Rico, including the Guánica Forest Biosphere Reserve. The species is considered Critically Endangered, mainly because of the industrial, residential and recreational development of the area, which has rapidly reduced the extent of suitable habitat. The potential negative effects of introduced mammalian predators such as cats and mongooses remain to be fully assessed.

[*Caprimulgus noctitherus*,
Guánica Forest,
Puerto Rico.

the Pantepui region of southern Venezuela, and the Pygmy Nightjar of north-east Brazil; and two others, the Long-trained Nightjar and the atypical Sickie-winged Nightjar. To these should be added at least two more species, the Cayenne Nightjar of French Guiana, still known only from the type specimen taken in 1917, and the newly discovered Bahian Nighthawk, described to science in 1994, about which very little is known.

In Africa only one species, Prigogine's Nightjar, is treated as globally threatened, and it is currently listed as Vulnerable. Known only from a single female taken from the Itombwe mountain forests in Zaire, the specimen lay misidentified in a Belgian museum for 35 years until it was formally recognized as a distinct species in 1990. As with the other African forest species, the Brown Nightjar and Bates's Nightjar, deforestation probably poses the greatest threat to this almost totally unknown species, but it is interesting to note that unidentified nightjars have been seen recently in the Itombwe forests and neighbouring regions, suggesting that it might not be too long before this species is rediscovered.

As if to highlight the difficulties involved in seeing, identifying and censusing nightjars, one need only turn to the case of the enigmatic Nechisar Nightjar (see Systematics). This proposed species takes its name from the national park in southern Ethiopia where it was found. Nechisar is a remote and rarely visited region that also falls within the range of another little-known east African form, the Star-spotted Nightjar, and further exploration is urgently needed to try to ascertain the current status of both forms, while hopefully also proving that the Nechisar Nightjar is a valid species.

A similar story to Prigogine's Nightjar can be seen in the Asian species, Vaurie's Nightjar, which is still known only from the type specimen taken from the deserts of Xinjiang in far western China. Although the specimen was originally obtained in 1929, its true identity remained unrecognized for 31 years, until the species was eventually described to science in 1960, although, as with the Nechisar Nightjar, its status as a distinct species is still open to doubt. Several other Asian and Oriental nightjars are rare and poorly studied, and of these only Bonaparte's Nightjar has so far been registered as Near-threatened. Several others urgently need a re-evaluation of their current status, including both

the Sumatran and the Javan populations of Salvadori's Nightjar, and the two New Guinean endemics, the Papuan Nightjar and Archbold's Nightjar. On Sulawesi there are two endemics, the Sulawesi Nightjar and Heinrich's Nightjar, both of which are poorly known and possibly at risk. The latter is especially worthy of further study as it shares a similar story to that of some other species already mentioned above: a large, dark, forest species that was described from a single female taken in 1931, it was not seen again until a possible sighting in 1993, followed by its definite rediscovery in 1996; with large-scale deforestation taking place throughout the island, urgent steps will be needed to protect its future. New Caledonia also has an endemic nightjar that has not been seen again since its original discovery in 1939. Described as the race *exul* of the White-throated Nightjar, the New Caledonian bird is nevertheless remarkably different from other forms of that species, and further studies may well prove it to be a species in its own right. Whatever it turns out to be, it is probably not common and will almost certainly require some form of immediate protection, if indeed it is eventually rediscovered in time.

Subfamily CHORDEILINAE

Genus *LUROCALIS* Cassin, 1851

1. Semi-collared Nighthawk

Lurocalis semitorquatus

French: Engoulevent à queue courte **Spanish:** Añapero Colicorto
German: Bändernachtschwalbe
Other common names: Short-tailed Nighthawk; Chestnut-banded/Natterer's Nighthawk (*nattereri*)

Taxonomy. *Caprimulgus semitorquatus* J. F. Gmelin, 1789, Cayenne. Formerly considered conspecific with *L. rufiventris*, with which probably forms superspecies. Race *nattereri* often considered a separate species. Population on Trinidad requires further study to ascertain subspecific status. Five subspecies currently recognized.

Subspecies and Distribution.

L. s. stonei Huber, 1923 - SE Mexico S through NE Guatemala and N Honduras to NE Nicaragua.
L. s. noctivagus Griswold, 1936 - Costa Rica and Panama S to coastal W Colombia and NW Ecuador.
L. s. semitorquatus (J. F. Gmelin, 1789) - NE Colombia and W & S Venezuela E through the Guianas, and extreme NW Brazil; also (probably this race) Trinidad and Tobago.
L. s. schaeferi Phelps & Phelps, Jr., 1952 - N Venezuela.
L. s. nattereri (Temminck, 1822) - E Ecuador, N & E Peru and Brazil S of Amazon S to N Argentina.

Descriptive notes. 19-29 cm; male 82-89 g, female 79-81 g. Sexes similar; wing-tips project well beyond tip of tail. Upperparts dark brown, speckled and spotted rufous and buff, no nuchal collar; wing-coverts dark brown, speckled and spotted rufous, tawny and buff, no scapular pattern; white throat patch; underparts dark brown, speckled greyish-white and pale buff, becoming tawny-buff barred brown on lower belly and flanks; both sexes lack white markings on wings and tail; iris dark brown, bill blackish, legs and feet brownish or greyish. Immature similar to adult, but upperparts and wing-coverts have brownish-white feathers, boldly spotted

tawny with blackish-brown tips, primaries broadly tipped brownish-white mottled brown, and all tail feathers narrowly tipped greyish-brown mottled brown. Races vary slightly in size and coloration; *nattereri* has darker, more densely barred underparts. **Voice.** Call is a repetitive, wader-like whistle, "too-it" or "to-ic", given in flight or occasionally from perches or ground; other flight calls include "kee-kee" or "kit-kit-kit" notes.

Habitat. Typically forested, wooded or partly wooded lowlands: rainforest, humid forest, forested foothills, second-growth semi-open woodland, plantations, scrubland and open countryside; also edges of forest, marshes and watercourses. Generally recorded from sea-level to 1800 m, occasionally to 2550 m.

Food and Feeding. Feeds on moths, beetles, bugs and other insects. Forages in flight.

Breeding. Breeds late Jan to early Apr in Panama, possibly May-Jun in Venezuela, Oct-Dec in Brazil, and late Nov to Jan in Argentina. Nest-site in tree alongside forest trail, near woodland clearing or beside road; no nest, egg laid in slight depression in tree branch. Clutch 1 egg, elliptical, whitish with brown and grey speckles, or light blue and streaked chestnut (possibly *nattereri* only); incubation period c. 22 days; chick covered in greyish down; fledging period c. 24 days.

Movements. Most populations possibly sedentary. Race *nattereri* may be migratory in S of range. In S Brazil, present only perhaps Oct to early Mar; possibly winters N to Venezuela.

Status and Conservation. Not globally threatened. In Central America, uncommon to frequent in Atlantic lowlands from extreme SE Mexico to Honduras; widespread and locally uncommon to common in Costa Rica; widely distributed in small numbers in Panama, where possibly increasing, resulting in slight expansion of range. In E Chiapas, Mexico, not recorded until 1989, and either previously undetected or has undergone a slight range expansion to N. In South America, widely distributed but possibly local in Trinidad; widespread and locally common in Surinam; local and uncommon in Colombia, where loss of habitat a potential threat in some regions; not recorded in Bolivia until 1980's but possibly overlooked, previous records attributable to *L. rufiventris*; common in E Paraguay but apparently much rarer in *campos cerrados* in N; in Brazil, widespread and fairly common in Amazonas drainage, common in Alagoas, and widely distributed and locally fairly common from Bahia S to Rio Grande Do Sul, where a common summer resident.

Bibliography. 2. Rufous-bellied Nighthawk

Lurocalis rufiventris

French: Engoulevent à ventre roux **German:** Andennachtschwalbe **Spanish:** Añapero Ventrirrufo
Other common names: Taczanowski's Nighthawk

Taxonomy. *Lurocalis rufiventris* Taczanowski, 1884, Peru. Formerly considered conspecific with *L. semitorquatus*, with which probably forms superspecies. Monotypic.

Distribution. Confined to Andes, from W Venezuela to SW Colombia, S through C Ecuador, W & S Peru to W Bolivia.

Descriptive notes. 25-25.5 cm. Sexes similar; wing-tips project well beyond tip of tail. Upperparts dark brown, speckled and spotted rufous and buff, no nuchal collar; wing-coverts dark brown, speckled and spotted rufous, tawny and buff, no scapular pattern; white throat patch; underparts dark brown spotted pale tawny and greyish-white, becoming tawny-buff on belly and flanks; both sexes lack white markings on wings and tail; iris dark brown, bill blackish, legs and feet brownish. Immature similar to adult, but upperparts and wing-coverts have brownish-white feathers, boldly spotted tawny with blackish tips, primaries broadly tipped brownish-white mottled brown, and all tail feathers narrowly tipped greyish-brown mottled brown. **Voice.** Call is a series of evenly pitched or descending "kwa" notes, given in flight; also "kwo-kwo-kwo" in flight.

Habitat. Montane rainforest, cloudforest, second-growth forest and forest edge, between 1650-3000 m.

Food and Feeding. Feeds on insects. Foraging methods not documented.

Breeding. Breeding habits not documented. Breeds from late Mar in Colombia; no other data.

Movements. Sedentary and possibly partially nomadic. Specimens have been taken in Brazil, but further data not available.

Status and Conservation. Not globally threatened. Widely distributed in suitable habitat along Andes, but uncommon and local, often remaining undetected in areas with little or no ornithological coverage; recent range extension reported from Chacha in S Ecuador.

Bibliography. Boesman (1998), Fjeldsá & Krabbe (1990), Fjeldsá & Mayer (1996), Hilty & Brown (1986), Kirwan & Marlow (1996), Krabbe *et al.* (1997), Meyer de Schauensee & Phelps (1978), Parker, Castillo *et al.* (1991), Parker, Parker & Plenge (1982), Stotz *et al.* (1996).

Genus *CHORDEILES* Swainson, 1832

3. Least Nighthawk

Chordeiles pusillus

French: Engoulevent nain **German:** Gnomennachtschwalbe **Spanish:** Añapero Menudo

Taxonomy. *Chordeiles ? pusillus* Gould, 1861, Brazil.

Sympatric with *C. vielliardi* in NE Brazil. Six subspecies currently recognized.

Subspecies and Distribution.

C. p. septentrionalis (Hellmayr, 1908) - E Colombia E to W Surinam and possibly W Brazil.
C. p. esmeraldae Zimmer & Phelps, 1947 - SE Colombia, S Venezuela and extreme NW Brazil.
C. p. xerophilus Dickerman, 1988 - extreme NE Brazil (Paraíba, Pernambuco).
C. p. novaesi Dickerman, 1988 - NE Brazil (Maranhão, Piauí).
C. p. pusillus Gould, 1861 - E Brazil (Tocantins, Bahia, Goiás).
C. p. saturatus Pinto & Camargo, 1957 - WC Brazil and extreme E Bolivia.
Also (race undetermined) extreme NE Argentina.

Descriptive notes. 15-19 cm. Sexually dimorphic, though not greatly so. Upperparts generally brownish, spotted greyish-white, buff and pale tawny, no nuchal collar; wing-coverts brownish, heavily spotted buff and pale buff, faint scapular pattern; small white patch on lower throat or small white spot on either side of lower throat; underparts brown spotted and barred buffish, becoming white barred brown on belly and flanks. Male has white band across four outermost primaries, white trailing edge to inner wing and white tips to inner webs of all but central pair of tail feathers; female has thinner white wing-band and buffish trailing

edge to inner wing, and lacks white tips to some or all tail feathers. Iris dark brown, bill blackish, legs and feet brownish. Immature similar to adult. Races vary mainly in size, coloration and barring of underparts. **Voice.** Song of male is a rapid "k-k-k-k-kuree" rising in pitch and occasionally ending in long churr; flight call short "whit" or "bit".

Habitat. Usually open savanna and grassland with scattered trees and scrub, occurring in both *cerrado* and *caatinga*; also clearings along forest edges, where savanna and scrubland have become established. In Bolivia also dry, seasonally flooded grassland and rocky hillsides. Generally a lowland species, occurring from sea-level to 1000 m.

Food and Feeding. Feeds on insects. Probably catches prey in flight, though foraging methods not documented.

Breeding. Poorly known. Breeds from Jan in Colombia, possibly Oct in S Venezuela, NW Brazil and NE Argentina; two nests recently reported from E Brazil, in Bahia and Minas Gerais, in late Jan and mid-Nov respectively; no data from other localities. Nest-site on ground with stony soil and sparse bush cover; no nest, egg laid directly on ground. Clutch 1 egg, elliptical, creamy-white, faintly blotched and spotted brown and purplish-grey; chick covered in rufous-buff down.

Movements. Poorly known. Although some populations may be largely sedentary, race *esmeraldae* known to move E through N Brazil after breeding season.

Status and Conservation. Not globally threatened. Generally common to abundant in suitable habitat throughout much of range, though status in many regions poorly documented. Rather common in Guyana, especially on savannas; fairly common in NE Santa Cruz, Bolivia, more so during

Jul-Oct; seasonally common May-Sept in Mato Grosso, Brazil. Recently recorded breeding in Misiones province, NE Argentina, though race involved undetermined.
Bibliography. Bates *et al.* (1992), Dickerman (1988), Dubs (1992), Forrester (1993), Friedmann (1948), Friedmann & Smith (1950), Hilty & Brown (1986), Kirwan & Sharpe (1999), Leite *et al.* (1997), Meyer de Schauensee & Phelps (1978), Sargeant (1994a), Schubart *et al.* (1965), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Willis & Oniki (1993).

4. Bahian Nighthawk *Chordeiles vielliardi*

French: Engoulevent du Bahia **German:** Bahianachtschwalbe **Spanish:** Añapero de Bahía
Other common names: Caatinga Nighthawk

Taxonomy. *Chordeiles vielliardi* Lencioni-Neto, 1994, Brazil. Only recently described; further study required, as species possibly more closely related to genus *Nyctiprogne* than to *Chordeiles*. Sympatric with *C. pusillus* in NE Brazil. Monotypic.
Distribution. E Brazil (N Bahia).

Descriptive notes. 17.5 cm. Upperparts dark chestnut spotted chestnut-brown, broadly streaked blackish-brown on crown; wing-coverts dark chestnut barred dark brown, scapulars blackish-brown edged chestnut-brown; lacks white throat patch; underparts dark chestnut-brown spotted and barred buff, becoming white barred dark chestnut on belly and flanks; lacks white markings on wings and tail; iris yellowish-brown, bill probably blackish, legs and feet yellowish-brown. Female unknown. Immature tawny than adult male, with blackish-chestnut spots on head, dark streaking on back and rump and whiter underparts; iris chestnut-brown, bill undescribed, tarsus chestnut-brown. **Voice.** Calls include series of soft "weet-weet" or "wik-wik" notes, given in flight or from perches.

Habitat. Caatinga woodland along riverbanks, especially where there are dunes and rocky outcrops.
Food and Feeding. Feeds on insects. Foraging methods not documented.
Breeding. First nest discovered in Nov 1998. No further information available.
Movements. None documented. Possibly sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in North-east Brazilian Caatinga EBA. True status unknown, but species only recently described to science, and probably requires treatment as Data-deficient. Recorded only from two sites along R São Francisco in E Brazil; recent reports of nest and at least 30 birds in area of Januária and Mocimbinho. Research and survey work required.
Bibliography. Anon. (1995c, 1995e, 1995f, 1998c), Lencioni-Neto (1994), Stattersfield *et al.* (1998).

5. Sand-coloured Nighthawk *Chordeiles rupestris*

French: Engoulevent sable **German:** Flußnachtschwalbe **Spanish:** Añapero Blanco
Other common names: White-throated Nightjar(!)

Taxonomy. *Caprimulgus rupestris* Spix, 1825, rocky islands in the Rio Negro, Brazil. Two subspecies recognized.
Subspecies and Distribution.
C. r. xyostictus Oberholser, 1914 - C Colombia.
C. r. rupestris (Spix, 1825) - NE Ecuador, NE Peru, SE Colombia and S Venezuela E through N & C Brazil and S to C Bolivia.

Descriptive notes. 19-24 cm. Sexes similar. Upperparts pale greyish-brown, mottled and streaked brown and cinnamon, no nuchal collar; wing-coverts pale greyish-brown, cinnamon and whitish, boldly spotted with blackish star-shaped markings, no scapular pattern; white throat patch; underparts greyish-white, tinged cinnamon, barred and spotted brown, becoming buff-tinged white on belly and flanks; both sexes have large white patch across back of wings, trailing edge and wing-tips blackish-brown, and all but central pair of tail feathers white, broadly tipped brown; iris dark brown, bill blackish-grey, legs and feet greyish-brown.

Immature similar to adult but paler. Race *xyostictus* is sandier than nominate. **Voice.** Call is a trilled "rrr-wo-wo-wo", given in flight or from perches; other calls include tern-like "ow-ow-ow".
Habitat. Mainly rivers and marshes in forest and secondary growth, on rocky islands, sandy beaches and sandbars; also near riverside villages and airstrips. A lowland species, recorded from sea-level to 500 m.

Food and Feeding. Feeds on insects, including moths and termites. Forages in flight, hunting low over sandbars and beaches or higher up above rivers. Also feeds over open country, usually near rivers, and on insects attracted to artificial lights. Often forages in loose flocks.
Breeding. Breeds during dry season in low-water periods, Jan and Jul to possibly late Sept in Colombia, May-Aug in Peru and Jun-Sept in Brazil; no data from other regions. Often in loose colonies of up to 200 pairs. Nest-site usually on sandbar or beach along river; no nest, eggs laid on sand. Clutch 1-2 eggs, elliptical, sandy-buff, possibly tinged bluish, and densely blotched and scrawled brown, laid at c. 24-hour intervals; replacement clutches may be laid if first lost through predation or flooding; incubation period c. 21 days; adults flushed from nest-site may perform injury-feigning distraction display; chick apparently not described.
Movements. Poorly known. Possibly some local movements in parts of range.
Status and Conservation. Not globally threatened. In Colombia, locally fairly common to common in suitable habitat, especially along Amazon, Orinoco and Negro rivers; very few published data from other regions. Eggs and chicks at risk from avian predators such as Bat Falcon (*Falco rufigularis*), Great Black Hawk (*Buteogallus urubitinga*), Roadside Hawk (*Buteo magnirostris*) and especially Black Caracara (*Daptrius ater*); humans probably most serious threat in many re-

gions, taking large numbers of eggs as part of local diet; reptiles such as snakes and iguanas occasionally take small numbers of eggs.
Bibliography. Allen (1995), Davis *et al.* (1994), Donahue (1994), Friedmann (1948), Groom (1989, 1992), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Oren & Parker (1997), Parker & Rowlett (1984), Parker *et al.* (1982), Remsen & Traylor (1989), Sargeant (1994a), Schubart *et al.* (1965), Sick (1950a, 1993, 1997), Stotz *et al.* (1996).

6. Lesser Nighthawk *Chordeiles acutipennis*

French: Engoulevent minime **German:** Texasnachtschwalbe **Spanish:** Añapero Garrapena
Other common names: Trilling Nighthawk

Taxonomy. *Caprimulgus acutipennis* Hermann, 1783, Cayenne. Birds of Baja California formerly separated in race *inferior*. Seven subspecies currently recognized.
Subspecies and Distribution.
C. a. texensis Lawrence, 1856 - SW USA S to C Mexico.
C. a. micromeris Oberholser, 1914 - N Yucatán Peninsula, Mexico.
C. a. littoralis Brodkorb, 1940 - S Mexico S through Central America to Costa Rica and possibly Panama.
C. a. acutipennis (Hermann, 1783) - Colombia E through Venezuela, Trinidad and Tobago and the Guianas and S through Brazil (absent from many parts of Amazonia) to N Bolivia and probably Paraguay.
C. a. crissalis A. H. Miller, 1959 - SW Colombia.
C. a. aequatorialis Chapman, 1923 - W Colombia, W Ecuador and possibly NW Peru.
C. a. exilis (Lesson, 1839) - W Peru and rarely extreme N Chile.

Descriptive notes. 19-23 cm; male 34-62 g, female 34-64 g. Sexually dimorphic; at rest, wing-tips reach tip of tail. Crown generally blackish-brown, rest of upperparts brownish, speckled greyish-white and boldly spotted blackish-brown; indistinct buffish or greyish-white nuchal collar; wing-coverts brownish, speckled greyish-white and greyish-brown, speckled and spotted buff, lower marginal coverts often white; scapulars blackish-brown, broadly bordered buff on outer webs; throat patch white (male) or buffish (female); underparts brownish, speckled and spotted greyish-white, cinnamon, tawny and buff, becoming buff

barred brown on belly and flanks. Male has white band across four outermost primaries and narrow white subterminal band across all but central pair of tail feathers; female has buffish or buffish-white wing-band and lacks white on tail. In flight both sexes show wing-band becoming narrower towards trailing edge of wing, with inner primaries above band spotted buffish. Iris dark brown, bill blackish, legs and feet brownish or greyish. Immature greyer or buffier than adult, with primaries and secondaries tipped greyish-white or tawny. Racial differences involve size, coloration and barring of underparts; extent of white wing and tail bands may also vary between males of some races. **Voice.** Song of male is an evenly pitched trill or slow churr. Sings in flight, from perches or ground. Courtship calls include winnowing or bleating sounds, slow, melodious trills, and long, nasal "whaa" and "whoo" calls and twangs; male also gives chucks, clucks and dove-like "c-r-rooo" calls; both sexes make guttural hissing sounds during distraction or defence displays; adult calls to offspring with soft "chunk" notes, chick utters a variety of weak "chee-uk" or "chee-ur" calls.
Habitat. Typically all types of open country, including deserts and semi-deserts, scrubland, savanna and farmland; also woodland, gardens, suburban areas, mangroves, salt lagoons and ocean beaches. Generally from sea-level to 1200 m, occasionally to 2500 m.

Food and Feeding. Diet includes crickets, beetles, winged ants, moths, mayflies, termites, dragonflies, flies, mosquitoes and bugs. Forages in flight by hunting low over savannas, fields, airstrips, roads and open country. Also feeds by making short sallies from ground. Occasionally forages during daytime, especially in overcast conditions.
Breeding. Breeds late Apr to Aug in SW USA, May-Jul/Aug in Mexico, possibly late Apr to Jul in El Salvador, Mar (perhaps) to Jul in Costa Rica, Feb-May in Trinidad and Tobago, Jun-Jul in N Colombia, Jan-Feb in S Colombia, and Feb-Mar in Ecuador; in some regions, breeding periods possibly longer than stated. Territorial; occasionally semi-colonial. Nest-site often near or beneath bush or close to vegetation, also on beach, boulders and flat roof of adobe house; no nest, eggs laid on sand, gravel, bare ground, leaf litter or possibly rock. Clutch 1-2 eggs, elliptical or elliptical-ovate, glossy, pale grey to pale creamy-white, speckled vinaceous-buff, spotted and marked grey, lilac and brown, or occasionally unmarked; incubation mainly by female, period generally 18-19 days; adults flushed from nest-site may perform distraction or defence display; eggs hatch asynchronously; chick semi-precocial, covered in buffish down with brownish mottling on upperparts; if threatened, older chicks may perform defence display by gaping and spreading wings, before running off; can fly short distances at c. 21 days of age.

Movements. Surprisingly little known; many populations possibly largely sedentary. Race *texensis* migratory, wintering from extreme S Baja California and C & S Mexico, S to Panama (Oct-Apr) and NW Colombia (Dec-Apr); occasionally also winters in S California and SW Arizona. Race *micromeris* also migratory, moving S through Central America and possibly across Gulf of Honduras; winters in Costa Rica and W Panama, possibly E to Canal Zone. S populations in South America possibly also migratory, moving N during austral winter. Often migrates in loose flocks, occasionally in large numbers. Vagrants have occurred in Ontario, Alabama, Florida, Bermuda and Trinidad.

Status and Conservation. Not globally threatened. Uncommon to locally abundant throughout range. On North American breeding grounds, locally common in California, Arizona, New Mexico and Texas; Breeding Bird Survey data for 1966-1991 suggest population generally increasing by 3.1-8.0% annually, although local declines possible in California, where loss of habitat due to mining and urbanization potential threats, and in New Mexico, where use of insecticides may be harmful. No data on territory size, though nests occasionally 25 m apart. Eggs may possibly be taken by avian predators such as Black-crowned Night Heron (*Nycticorax nycticorax*), by snakes and by mammalian predators including coyote (*Canis latrans*), kit fox (*Vulpes macrotis*), raccoon (*Procyon lotor*) and striped skunk (*Mephitis mephitis*); Loggerhead Shrikes (*Lanius ludovicianus*), Greater Roadrunners (*Geococcyx californianus*) and coyotes may possibly take chicks. Widespread and fairly common throughout much of Mexico, where also a common passage migrant and winter visitor; avian predators include Aplomado Falcon (*Falco femoralis*). Common passage migrant

through Guatemala and possibly an uncommon resident in some regions. Rare breeding species in El Salvador, first discovered nesting at two sites in Jun 1994, with 6 pairs at mouth of Río Lempa, San Vicente and 1 pair at Arcos del Espino, Usulután. Fairly common to abundant locally in Pacific lowlands of Panama, increasing between late Jul and Apr with arrival of migrants from farther N; birds once killed, dried and sold in local markets as love-charms, though no recent data on such practices. Common breeder and migrant in Trinidad, particularly common Aug-Oct. Reasonably common and locally numerous in Surinam; widespread and common in Guyana; locally uncommon to common in open, dry country in Colombia, numbers augmented outside breeding season by migrants from North & Central America. In many countries, increasing road traffic and high use of insecticides are potential threats, though no data available on effects on local populations.

7. Common Nighthawk

Chordeiles minor

French: Engoulevent d'Amérique **German:** Falkennachtschwalbe **Spanish:** Añapero Yanqui
Other common names: Booming Nighthawk

Taxonomy. *Caprimulgus minor* J. R. Forster, 1771, no locality = South Carolina.

Formerly considered conspecific with *C. gundlachii*, but the two are sympatric in S Florida. Nine subspecies currently recognized.

Subspecies and Distribution.

C. m. minor (J. R. Forster, 1771) - most of C & S Canada S to N & NE USA.

C. m. hesperis Grinnell, 1905 - SW Canada and W USA.

C. m. sennetti Coues, 1888 - CS Canada and NC USA.

C. m. howelli Oberholser, 1914 - WC & SC USA.

C. m. henryi Cassin, 1855 - SW USA and CN Mexico.

C. m. aserriensis Cherrie, 1896 - SC USA and extreme NE Mexico.

C. m. chapmani Coues, 1888 - SE USA.

C. m. neotropicalis Selander & Álvarez del Toro, 1955 - E & S Mexico, and possibly this race in Guatemala.

C. m. panamensis Eisenmann, 1962 - Nicaragua S to Panama, and possibly also N to E Honduras and Belize.

Winters in N & E South America.

Descriptive notes. 22-25 cm; male 46-107 g, female 49-101 g, average appears c. 80 g. Sexually dimorphic; at rest, wing-tips usually extend well beyond tip of tail. Crown dark brown spotted buff or tawny, upperparts brown or blackish-brown, spotted and speckled greyish-white, buff and cinnamon; no nuchal collar, although nape is spotted buff, occasionally heavily so; lesser coverts dark brown, lightly spotted greyish-white, cinnamon or pale buff, rest of wing-coverts brown, speckled and spotted greyish-white, white or pale buff, lower marginal coverts white, faint scapular pattern; supercilium greyish-white; throat patch white

(male) or buffish (female); underparts brown barred greyish-white, becoming greyish-white tinged buff and barred brown on belly and flanks, female having buffier underparts. Male has broad white band across five outermost primaries and broad white subterminal band across all but central pair of tail feathers; female has thinner, less distinct white wing-bands and lacks white on tail. In flight both sexes have white wing-band broader towards rear, inner primaries above band appearing blackish and unmarked. Iris dark brown, bill blackish, legs and feet brownish. Immature similar to adult but with underparts more heavily barred, throat patch paler and spotted, no white subterminal band on tail, and all primaries and secondaries narrowly tipped white. Races vary mainly in size, coloration, barring of underparts and, especially in males, extent of white wing and tail markings. **VOICE.** Territorial/courtship call of male is a nasal "peent", usually in flight; other calls of male include "kit-kit" or "yap-yap" in flight and "cho-ic" or "che-wip" alarms; when pairs together, male gives nasal growls or croaks, female responds with guttural "kra-a" calls; at nest, female utters variety of guttural hisses, grunts and chuckles; guttural hissing sounds given during threat or defence displays; adult uses soft, nasal "kurr" or "chuk" notes to summon offspring, chick gives soft "peep" calls.

Habitat. Favours open or semi-open arid country: savanna and open grassland, plains, grassland with scattered trees, fields, pastures, marshland, airstrips, golf courses, barren hillsides and gravelly ridges; also open forest and wood, thick spruce forest, woodland edge, burnt habitats, rocky brushland, sand dunes, beaches, desert scrub flats, coral flats with scattered vegetation, towns and cities, and edges of roads and railway tracks. In Central America, also in more humid regions. Occurs from sea-level to 2600 m.

Food and Feeding. Diet includes moths, bugs, wasps, flies, mosquitoes, mayflies, caddisflies, gnats, flying ants, plant lice, grasshoppers, locusts, crickets and beetles. Wood, vegetation and gravel are also ingested, possibly accidentally with prey. Forages in flight, occasionally very high up, over open country or water. Large numbers may forage together, feeding flocks of up to 300 having been recorded. Also feeds on insects attracted to fires and artificial lights.

Breeding. Breeds May-Jul in Canada, late Apr to Aug in N USA, late Mar to Aug in S USA, and mid-May to Aug in Central America. Occasionally double-brooded. Territorial, though occasionally breeds in loose flocks, and occasionally in loose colonies with sympatric *C. gundlachii*. Nest-site in open, barren country, in forest or wood, on beach or coral flats, in field, vineyard or garden, on stump or fence rail up to 2.5 m above ground, between rails on railway track, or on gravel roof up to 14.5 m above ground in towns and cities; no nest, eggs laid on ground, leaf litter or pine needles, gravel, brick rubble, burnt land, sand, rock or occasionally coarse moss, lichens or other vegetation.

Male performs aerial courtship display by diving steeply and producing booming sound with wings. Clutch 1-3 (usually 2, very rarely 3) eggs, elliptical and variable in colour, from dull white, greyish-white or pale creamy-white to creamy olive-buff or olive-grey, speckled and streaked grey, black, brown, olive and lilac; incubation usually by female, period generally 17-20 days; adults threatened at nest-site may perform defence or distraction displays; chick semi-precocial, covered in grey and buff down, blotched blackish-brown, fed by regurgitation, may perform threat/defence display if threatened; young often brooded for up to 20 days, though can make short flights at c. 18 days of age and catch own food at c. 25 days.

Movements. Highly migratory, breeding throughout North & Central America and wintering in South America, possibly as far S as N Patagonia. Migrates in loose flocks, large numbers often passing along favoured routes. Nominate race leaves breeding grounds late Jul to early Oct (mainly mid-Aug to early Sept), generally moving S through Central America, although some E populations may use transoceanic routes, as regular and occasionally very common autumn migrant on Bermuda. Winters in South America E of Andes, as far S as N Argentina. In spring, returning birds arrive on breeding grounds late Apr to late May (mainly middle to late May). After breeding season, race *sennetti* moves S through Colorado, Texas and Oklahoma, then possibly through E side of Central America. Race *hesperis* moves S through SW USA and Central America, although occasionally recorded E of normal routes. Race *henryi* moves SE through Central America, and possibly across Gulf of Mexico. Race *howelli* moves S through CS USA, Mexico and Nicaragua. Race *chapmani* possibly moves SE and winters from C Brazil to N Argentina. Race *neotropicalis* leaves breeding grounds in Aug and probably Sept. In spring, returning birds may begin arriving in Jan, though most not until Mar-May. Race *aserriensis* moves SE through Central America. Movements of race *panamensis* poorly documented. Vagrants have occurred in autumn in Iceland, Faeroes, Britain (mid-Sept to late Oct), at sea near Azores, and on Tristan da Cunha (late Nov).

Status and Conservation. Not globally threatened. Widespread and generally common throughout much of breeding range; widespread and locally fairly common in Mexico, where also a common passage migrant; common passage migrant in Guatemala, where may also possibly breed in small numbers; locally common to abundant in much of S Central America, e.g. in Panama a common passage migrant during spring and autumn but less common and more local as a breeding species. Widespread on South American wintering grounds, mainly E of Andes, with main range possibly E Ecuador E to S Brazil and S to Argentina. In Colombia an uncommon to fairly common autumn migrant, late Aug to late Nov, and some may overwinter; rarer in spring, Mar-Apr; winter visitor to E Ecuador, but more numerous as a passage migrant; regular winter visitor in E Peru; in Venezuela a passage migrant and possibly winters in small numbers; in Brazil a winter visitor Oct-Mar, and although most records are from S states, possibly under-recorded elsewhere; widespread and fairly common winter visitor in Paraguay; regular winter visitor in Uruguay; possibly fairly widespread in Argentina, winter range extending S to Catamarca and Buenos Aires. On breeding grounds, territory size 4-14-33-6 ha, where potential predators likely to include crows (*Corvus* sp.), falcons, especially Peregrine (*Falco peregrinus*) and American Kestrel (*Falco sparverius*), gulls (*Larus* sp.), owls (Strigidae), coyotes (*Canis latrans*), foxes (Canidae), skunks (Mustelidae), snakes, and in urban environments domestic dogs and cats; no data from wintering range. In North America, Breeding Bird Survey data show probable decline in populations, 1966-1991, in both USA and Canada, although local increases apparent over same period in Iowa, Kansas, N Dakota, Oklahoma, Utah and Vermont; listed as a species of concern (Blue List) by British Columbia Ministry of Environment 1975-1981, but not 1978, and again in 1986.

8. Antillean Nighthawk

Chordeiles gundlachii

French: Engoulevent pyramide **German:** Antillennachtschwalbe **Spanish:** Añapero Querequeté

Taxonomy. *Chordeiles gundlachii* Lawrence, 1856, Cuba.

Formerly considered conspecific with *C. minor*, but the two are sympatric in S Florida. Two subspecies recognized.

Subspecies and Distribution.

C. g. vicinus Riley, 1903 - S Florida and Bahamas.

C. g. gundlachii Lawrence, 1856 - Cuba and I of Pines; Cayman Is, Jamaica, Hispaniola, Puerto Rico and Virgin Is.

Wintering grounds unknown.

Descriptive notes. 20-21 cm. Sexually dimorphic; two colour morphs, greyish and tawny; at rest, wing-tips occasionally do not reach tip of tail. Crown darkish brown spotted pale buff, upperparts brown or blackish-brown, densely spotted greyish-white, buff and cinnamon; no nuchal collar, nape being brown spotted pale buff and greyish-white; lesser coverts dark brown, lightly spotted greyish-white, pale buff or cinnamon, rest of wing-coverts brown, speckled and spotted greyish-white and cinnamon, lower marginal coverts white, faint scapular pattern; supercilium greyish-white; throat patch white (male) or buffish (female); underparts brown barred greyish-white, becoming buffish barred brown on belly and flanks. Male has

broad white band across five outermost primaries and broad white subterminal band across all but central pair of tail feathers; female has less distinct white wing-bands and lacks white on tail; in both sexes inner primaries above white wing-band appear blackish and unmarked. Iris dark brown, bill blackish, legs and feet brownish. Immature similar to adult but with underparts more heavily barred, throat patch paler and spotted, no white subterminal band on tail, and all primaries and secondaries narrowly tipped white. Race *vicinus* apparently smaller than nominate form, and has only greyish colour morph. Voice. Territorial/courtship call of male is a repetitive "chitty-chit" or "killikadik", usually given in flight; also gives nasal "penk-dik".

Habitat. Mainly open or semi-open arid country, including recently cleared areas. In Puerto Rico, also limestone forest.

Food and Feeding. Feeds on moths, beetles and other insects. Forages in flight, hunting high up over forests, shorelines, fields, pastures and towns. Feeding birds hunt alone, in pairs or in small flocks. Recorded foraging during daytime, in overcast conditions.

Breeding. Breeds mid-Apr to mid-Aug in Florida, and Apr-Aug in Bahamas, Cuba, I of Pines, Jamaica, Hispaniola and Puerto Rico. Territorial, though occasionally nests in loose colonies with sympatric *C. minor*. Nest-site in open patch of ground, among pebbles or small stones, in cavity of rough coral rock or occasionally on dirt track; no nest, eggs laid on ground, on gravel or sand. Male performs aerial courtship display flights, diving steeply and producing booming sounds with wings. Clutch 1-2 eggs, pale greyish to greenish-white, blotched and scrawled dark grey and plumbeous; incubation mainly by female, period c. 19 days; chick semi-precocial, covered in cinnamon-brown, greyish-brown or creamy-buff down with greyish-black markings.

Movements. Highly migratory, though wintering areas undocumented. Both races leave breeding grounds by Aug (probably) and Sept, and begin returning in Apr. Outside North American breeding range, recently reported from Texas and North and South Carolina.

Status and Conservation. Not globally threatened. Generally quite common throughout much of breeding range. In Cuba, extremely common Mar-Aug in open savannas and cane-fields; on Isle of Pines common on savannas and along infrequently used railway tracks. Common in Hispaniola and Puerto Rico during Aug. Race *vicinus* has apparently undergone slight range expansion: first noted on Florida Keys 1941 and now breeding there in small numbers; since 1957 also occasionally reported from Florida mainland.

Bibliography. Anon. (1998a), Baicich & Harrison (1997), Balát & González (1982), Barbour (1943), Biaggi (1983), Bond (1985), Buden (1987a, 1987b), DeGraaf & Rappole (1995), Dod (1987), Eisenmann (1962), Greene (1943), Kaufman (1996), Kepler & Kepler (1973), LeGrand (1996), Monroe (1968), Nicholson (1950, 1957), Oberholser (1914), Raffaele (1989), Raffaele *et al.* (1998), Robertson (1978), Smith (1996), Stevenson *et al.* (1983), Stotz *et al.* (1996), Vaurie (1957), Wetmore & Swales (1931).

Genus *NYCTIPROGNE* Bonaparte, 1857

9. Band-tailed Nighthawk

Nyctiprogne leucopyga

French: Engoulevent leucopyge

Spanish: Añapero Colibandeado

German: Bindenschwanz-Nachtschwalbe

Taxonomy. *Caprimulgus leucopygus* Spix, 1825, wooded shores of the Amazon.

Five subspecies recognized.

Subspecies and Distribution.

N. l. pallida Phelps & Phelps, Jr., 1952 - W & C Venezuela and possibly NE Colombia.

N. l. leucopyga (Spix, 1825) - E Venezuela E through the Guianas and N Brazil.

N. l. exigua Friedmann, 1945 - S Venezuela and E Colombia.

N. l. latifascia Friedmann, 1945 - extreme S Venezuela.

N. l. majuscula Pinto & Camargo, 1952 - W & C Brazil and N & E Bolivia; recently recorded in NE Peru.

Descriptive notes. 16-20 cm; male 23-24 g, female 23-26 g. Sexes similar. Upperparts brown, speckled pale brown, greyish-brown and cinnamon, no nuchal collar; wing-coverts brown, speckled and spotted pale brown, greyish-brown and cinnamon; scapulars blackish-brown, broadly edged buff on outer webs; small white patch on either side of lower throat; underparts brown, speckled cinnamon and barred buff, becoming greyish-white barred brown on belly and flanks. Both sexes lack white markings on wings but have prominent white band midway across three outermost tail feathers. Iris dark brown, bill

blackish, legs and feet blackish. Immature similar to adult but slightly paler and plainer. Races vary in size and intensity of overall coloration. Voice. Song of male is a treble-noted "gole-kwoik-kwak"; calls include soft, guttural "qurk" notes.

Habitat. Typically forest and savanna, usually near water: rainforest, gallery forest, forest edges, clearings, savannas and banks of large rivers; also by marshes, ponds, streams and rivers. A lowland species, recorded from sea-level to 500 m.

Food and Feeding. Diet includes beetles, bugs and ants. Forages in erratic flight, hunting over open country, marshland and riverside vegetation, along riverbanks and above water. Occasionally, feeding flocks may contain 60 or more individuals.

Breeding. Poorly known. Breeds Jan to probably Mar in Venezuela and perhaps Guyana; no data from other regions. Eggs whitish, speckled pale and dark grey.

Movements. None documented. Possibly sedentary.

Status and Conservation. Not globally threatened. Locally numerous to fairly common near water in E Colombia; fairly widespread but local in Venezuela; locally common in Amazonian Brazil and widely distributed and common, especially May-Oct, in Mato Grosso; probably fairly abundant along Rio Iténez/Guaporé in Bolivia.

Bibliography. Bates *et al.* (1989), Begazo & Valqui (1998), Davis *et al.* (1994), Dubs (1992), Friedmann (1945, 1948), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Oren & Parker (1997), Parker, Castillo *et al.* (1991), Parker, Parker & Plenge (1982), Remsen & Traylor (1989), Sargeant (1994a), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), de Urioste (1994).

Genus *PODAGER* Wagler, 1832

10. Nacunda Nighthawk

Podager nacunda

French: Engoulevent nacunda

German: Weißbauch-Nachtschwalbe

Spanish: Añapero Ñacundá

Taxonomy. *Caprimulgus nacunda* Vieillot, 1817, Paraguay.

Two subspecies currently recognized.

Subspecies and Distribution.

P. n. minor Cory, 1915 - N & C Colombia E through Venezuela, Trinidad, the Guianas and N Brazil.

P. n. nacunda (Vieillot, 1817) - E Peru E through Brazil (S of Amazon) and S to C Argentina.

Descriptive notes. 27-5-32 cm; male 142-188 g, female 124-170 g. Sexually dimorphic. Upperparts and wing-coverts brown speckled greyish-white and greyish-brown, heavily spotted blackish, no scapular pattern and no nuchal collar; large white throat patch, may show only as white band; underparts brown spotted buff, becoming white on belly and flanks, unmarked (male) or barred brown (female). Male has white band across five or six outermost primaries and broad white tips to all but central pair of tail feathers; female has smaller white wing-band and lacks white on tail. Iris brown, bill brown with dark tip, legs

and feet greyish-brown. Immature similar to adult female. Race *minor* smaller, paler and plainer than nominate. Voice. Song of male is a soft, repetitive "prrrrr-doo", usually given from ground, occasionally from perches; calls include short "whup" and melodious "cherk" notes.

Habitat. Savanna, grassland and marshland, also edges of rainforest and gallery forest, river edges, seashores and xerophytic country, from sea-level to 1000 m.

Food and Feeding. Diet includes froghoppers, beetles, bugs, winged ants, dragonflies, damselflies, Orthoptera, moths, earwigs and flies. Forages in flight, high up over marshes, reservoirs, open country and cities, and also hunts along rivers. Also feeds on insects disturbed by fires or attracted to artificial lights.

Breeding. Poorly documented. Breeds possibly Apr in Trinidad, Jan to perhaps Jun in Colombia, mid-Sept to Nov in Brazil, Nov in Uruguay and Bolivia, and Oct-Nov in Paraguay. Nest-site usually on rocky outcrop in grassland or on rocky ground beside marsh; no nest, eggs laid on leaf litter on ground. Clutch 1-2 eggs, elliptical, cream or pinkish-cream, spotted, blotched and scrawled brown, lavender and grey.
